LECTURES ON CLUB-FOOT.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK (SPECIAL COURSE).

By JOS. C. HUTCHISON, M.D.

VISITING SURGEON TO THE BROOKLYN CITY HOSPITAL; SURGEON-IN-CHIEF TO THE BROOKLYN ORTHOPEDIC INFIRMARY; CONSULTING SURGEON TO THE KINGS COUNTY, ST. PETER'S AND ST. JOHN'S HOSPITALS, ETC.

LECTURE VI.

TALIPES EQUINUS—PATHOLOGICAL ANATOMY—CAUSES—TREATMENT—EQUINO-VARUS AND EQUINO-VALGUS—TREATMENT.

TO-DAY, gentlemen, we will consider the simplest and most frequent form of club-foot, *talipes equinus*, or *horse-foot*, so called from its supposed resemblance to the foot of the horse.

In the opinion of all authors, simple equinus is rarely congenital, but we find at birth combinations of this distortion with other varieties, such as equinus varus and equinus valgus. "I have met," says Mr. Tamplin, "with pure *talipes equinus congenitus*." It usually occurs in infants under five years of age, but it may commence much later in life.

In well-marked cases of *talipes equinus* there is complete elevation of the heel, unaccompanied by lateral distortion, either inward or outward, increase in the concavity of the longitudinal arch, producing shortening of the foot, and a corresponding prominence of the head of the astragalus on the dorsum. The patient in walking rests entirely on the heads of the metatarsal bones, which become separated from each other in consequence of the pressure of the weight of the body, so that the anterior part of the foot is increased in width.

These appearances are well shown in the cast which I hold in my hand (Fig. 20), which represents a classical case of *talipes equinus* in the adult. There are, however, various degrees of the deformity, depending on the amount of flexion in the tibio-tarsal articulation. We may have simply *rectangular contraction of the tendo Achillis*, a condition in which the heel touches the ground and the movements of the ankle-joint are free, except when the patient attempts to raise the foot beyond the right angle when the leg is extended, giving rise to great inconvenience in walking; or the deformity may involve the utmost possible elevation of the *os calcis*.

The toes are usually in a condition of forced extension—drawn up at right angles to the metatarsal bones, as you see in this cast (Fig. 21). This indicates that the anterior muscles of the foot and leg retain their power; and when they are affected with spasm, the toes are flexed upon themselves, as seen in this cast (Fig. 22).

In exceptional cases, all the anterior muscles are

completely paralyzed, and the ligaments are greatly relaxed. The foot then becomes bent upon itself, so

FIG. 20.

FIG. 21.

that the dorsal surface rests upon the ground. This condition is well represented by the cast (Fig. 23).

When we study the *pathological anatomy* of this deformity, we find that the *bones* have undergone very little change in form. This is true even in cases which, beginning in childhood, have existed for many years. The *position* of the bones, however, is materially altered. The tuberosity of the *os calcis* is

FIG. 22.

FIG. 23.

raised by the contraction of the *gastrocnemius* and *soleus* muscles, sometimes to such a degree that the upper surface of this bone is brought in contact with the posterior surface of the tibia. The degree of elevation of the heel depends not merely on the amount of contraction of the muscles of the calf, but also on the amount of flexion of the anterior or the posterior part of the foot at the transverse tarsal joint.

The degree of elevation of the heel is often more apparent than real. The elevated position of the *os calcis* causes the *astragalus* to project downward and forward, and its head presents prominently on the dorsum of the foot (Fig. 20).

The metatarsal bones approximate to a vertical position, and, in old and severe cases, their anterior ex-

tremities are separated laterally, thus increasing the breadth of that part of the foot. In the cases already mentioned, when the paralysis is complete and the foot is retroverted, the metatarsal bones are situated at right angles to the leg, as seen in this cast (Fig. 23).

The ligaments are either elongated or contracted, according to their situations on the anterior or posterior surfaces of the foot, and in proportion to the degree and duration of the deformity. The muscles chiefly concerned in the production of talipes equinus are the triceps suræ, which elevate the os calcis, and the flexor brevis digitorum, which contracts the longitudinal arch of the foot. The plantar fascia is also contracted. The structure of the muscles will be found in varying stages of fatty and fibrous degenerations, the changes depending upon the cause and duration of the deformity. In cases of paralytic origin especially, fatty and fibrous degeneration usurp the place of normal muscular fibre, while in cases of spasmodic origin and those arising from injuries, the healthy muscular tissue has degenerated very much less.

Causes.—By far the most frequent causes of non-congenital talipes equinus are muscular spasm of the triceps suræ and paralysis of the anterior muscles of the foot and leg. It also arises from wounds of the gastrocnemius, or the nerves supplying that muscle, and abscesses occurring in the course of the muscle, and about the ankle joint, long-continued unchanged position, scrofulous and rheumatic inflammations of the ankle-joint.

Prognosis.—With regard to the prognosis of talipes equinus, we must consider, in the first place, the nature of the cause—whether the ankle-joint is directly or indirectly affected.

In the former class of cases, the deformity depends usually upon paralysis of the flexors of the foot, and contraction of the triceps suræ, and the prognosis is based upon the degree of paralysis and the condition of the muscular structure.

When it is produced by a puncture or other wound of the muscles of the calf or their nerve-trunks, or abscesses in the course of the muscle or in the neighborhood of the ankle-joint, the prognosis is generally favorable, both as regards the removal of the deformity and the restoration of the functions of the foot.

When the distortion arises from causes directly affecting the joint, such as rheumatic or scrofulous inflammation, in which there is a strong disposition to bony ankylosis, the prognosis is less favorable.

The age of the patient, as well as the duration and degree of the deformity, have an important influence on the length of the treatment, and also on the ultimate result, and should cause you to be guarded in your prognosis.

In a large majority of cases the deformity can be removed by appropriate treatment, and the foot can be kept in proper position by suitable appliances; but to re-establish free motion and complete voluntary power over the foot, and to give tone to the muscles, is not so easily accomplished, especially when the distortion is due, either to complete paralysis of the flexor muscles, or to causes directly affecting the interior of the joint. In cases of long standing the bones themselves participate in the deformity, and of course this malformation exercises a material influence on the prognosis.

The treatment of talipes equinus involves the use of mechanical, physiological, and operative means depending upon the cause and degree of the deformity.

For cases caused by paralysis of the flexor muscles

the physiological and mechanical treatment is usually sufficient. We should endeavor to overcome the paralysis according to the rules previously suggested for the physiological treatment, viz., by passive exercises, frictions, dry heat, massage, electricity, etc.

We should at the same time endeavor to counterbalance the action of the extensors by the use of the apparatus I here show you (Fig. 24). It consists of two

FIG. 24.

lateral upright bars fastened to the iron sole of a strong shoe, jointed at the ankle and connected to a band below the knee. A stout elastic strap extends from a stirrup over the toes to the calf-band and supplies the place of the paralyzed flexors. This strap may be regulated to any degree of tension. The heel is retained in its place by a strap across the instep.

In mild cases—those in which the foot can be flexed with the hand—the apparatus, conjoined with the physiological treatment, will be sufficient to accomplish a cure. If these means fail, shall we, in paralytic cases, resort to tenotomy? This will depend upon the degree of paralysis of the flexors and the degree of contraction of the extensors. If there is complete paralysis of all the anterior muscles of the leg, with but slight contraction of the posterior muscles, I have no hesitation in saying that no benefit will result from the operation. The paralysis is, however, usually limited to a few muscles, while others retain a considerable amount of power. The muscles involved and the degree of paralysis can be quite accurately determined by galvanization.

When the paralysis is not complete, I should recommend section of the tendo Achillis, for it is a matter of experience that the removal of the contraction materially aids in the restoration of power to the paralyzed muscles.

The tendo Achillis must be divided in the manner previously described (page 503, vol. xiv.), and the subsequent treatment consists in keeping the foot at rest in its abnormal position for three or four days, by the use of a plaster splint, and afterwards apply the apparatus just described (Fig. 24).

The tension of the elastic strap should be so regulated as to bring the foot very gradually to its normal position, not making the extension too rapidly, lest the connecting medium be too much elongated and thus destroy the function of the gastrocnemius, or produce the opposite condition, calcaneus, nor so slowly that the tendon will be reunited before the distortion has been entirely removed. The extension should be completed in about six weeks.

What shall we do for cases of rectangular contrac-

tion of the tendo Achillis? In these cases you will remember that the heel touches the ground in standing, and there is sufficient contraction of the tendo Achillis to prevent flexion of the foot beyond a right angle with the leg, but there is no obvious deformity. This slight contraction, however, gives rise to serious inconvenience and lameness, as you can readily understand when you remember that we raise the foot beyond the right angle in every act of walking or running.

This class of cases may arise from any of the causes of talipes equinus already enumerated, and we may say generally that the same rules of treatment apply to them as to other cases, with the exception that in no case should tenotomy be performed unless the muscles are in a healthy condition. In other conditions the operation may often be performed with great benefit to the patient.

In cases of talipes equinus, the *result of active contractions or spasm of the extensor muscles*, or arising from causes affecting the joint, the treatment should be initiated by tenotomy.

Passive exercises, electricity, etc., even when combined with mechanical treatment, will not overcome the distortion, except in very recent and slight cases; but they are useful adjuvants to the operative treatment. If any of the joints that are essential to the proper movements of the foot are ankylosed, it will be useless to attempt a cure even by a section of the different tendons.

The tendo Achillis is usually the only tendon requiring division; but occasionally you will find the posterior tibial and the peronei so tense that the foot cannot be flexed, even by considerable force, after the tendo Achillis has been divided, thus making their division also necessary.

You are not often required to divide either the plantar fascia or the flexors of the toes, although they may appear quite tense and contracted before any tendons are divided. You will find that the contraction of the longitudinal arch of the foot disappears, and that the toes assume their natural position, at least as a general rule, when the foot has been brought to a rectangular position with the leg. Should they not do so, the division either of the flexor tendons or the plantar fascia, or both, in severe cases of long standing may become necessary.

TREATMENT AFTER OPERATION.

After the cutaneous punctures have healed, Scarpa's shoe must be applied, and gradual mechanical extension made, until the foot is restored to its normal position. The extension, you understand, should be so conducted as to regulate properly the length of the new material uniting the divided extremities of the tendon.

The physiological treatment must be employed as soon as the position of the foot has been restored by mechanical means, for the purpose of establishing the functions of the joints and muscles; for you would commit a very grave error if you limited your treatment merely to the removal of the malposition of the foot. "To restore the foot to its normal position," says Malgaigne, "is not to cure it, any more than we cure a fracture when we try to reduce it." Unless the power to use the limb has been restored, but little benefit has been conferred upon the patient. Electricity, shampooing, dry heat, and flexion and extension of the foot for a quarter of an hour two or three times a day are the means to be used, in these and similar cases, until the parts are brought into as healthy a condition as can be obtained.

It is often necessary, after the distortion has been removed and the functions of the joints restored, to support the ankles by two side steel supports attached to the boot, having joints corresponding to the ankle-joints and connected at the calf by a metal plate, to which a strap is attached fastening in front. A stop-joint at the ankle may be used if necessary. With this apparatus, and proper attention to exercise, there need be no apprehension of re-contraction taking place.

Equino-varus and equino-valgus are compound varieties of club-foot, characterized by a certain amount of inversion or eversion of the anterior portion of the foot, in addition to the elevation of the heel, which is the marked feature.

The special form of distortion is determined by the relative power of the adductors and abductors of the foot. The deformity is well shown in these casts

FIG. 25.

FIG. 26.

(Figs. 25 and 26). The prognosis, pathology, and treatment of both the compound varieties are essentially the same as that of simple talipes equinus, except that, in order to control the lateral inclination of the foot, it may be necessary to have the sole of the shoe divided transversely at a point corresponding to the transverse tarsal joint (Figs. 12 and 13).

A PIN FOUND IN THE APPENDIX POST-MORTEM.—Dr. L. T. Morrill, of Albany, N. Y., found the following whilst making a post-mortem upon the body of a man, *æt.* 48, killed by a railroad accident: "An old cicatricial scar at the junction of the appendix and cæcum. The appendix measured four inches in length." On making section, a common-sized *pin* was found within. Its centre was covered by a faecal concretion, the head and point being free, however. There were no signs of recent inflammation about the appendix. The patient had never complained of any local symptoms.

SODIUM ETHYLATE A CURE FOR NEVUS.—This substance is prepared by adding metal sodium, piece by piece, to absolute alcohol, in a wide-mouth bottle, until effervescence ceases, when a deposition of a crystalline substance— C_2H_5NaO —occurs. The clear liquid is the part used. It is a potent caustic. Repeated applications thereof over the nevus resulted in cure in two cases reported by Dr. Brunton to the *Lancet*. It causes less pain and scarring than acid nitric.

TRANSFUSION OF MILK VERSUS TRANSFUSION OF BLOOD.

CLINICAL LECTURE DELIVERED AT CHARITY HOSPITAL, NOVEMBER 23, 1878.

By JOSEPH W. HOWE, M.D.,

CLINICAL PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK.

LECTURE III.

(Reported for THE MEDICAL RECORD.)

REMARKABLE IMPROVEMENT FROM TRANSFUSION OF BLOOD IN SYPHILIS AND PHTHISIS—REPETITION OF OPERATION IN SYPHILIS AND PHTHISIS—RESULTS OF SIX OPERATIONS WITH COLIN'S INSTRUMENT AND DEFIBRINATED BLOOD—RESULTS OF ONE OPERATION WITH AVELING'S INSTRUMENT—TRANSFUSION WITH A GLASS FUNNEL AND RUBBER TUBE—IS TRANSFUSION OF MILK A JUSTIFIABLE OPERATION WHEN BLOOD CAN BE OBTAINED?

GENTLEMEN:—Last Saturday those two patients were brought to this amphitheatre in a very low condition. One was suffering from syphilis and phthisis; the other had phthisis in the third stage. They were both transfused with blood. To-day they are able to walk to the amphitheatre without assistance. The patient with syphilis was transfused with undefibrinated blood mixed with ammonia. Half an hour after the operation he was seized with a chill, which lasted fifteen minutes. His temperature during the chill was $100\frac{1}{4}^{\circ}$ F., and his pulse was 120 per minute. Two hours subsequently his pulse ran up to 158, and his temperature increased to 103° , and he expectorated a small quantity of bloody mucus. At 10 P.M. the same evening his pulse went down to 116, and the temperature decreased to $100\frac{1}{4}^{\circ}$. At 6 P.M. the day following, his pulse was only 88, and his temperature $99\frac{3}{4}^{\circ}$. On the third day after the operation the syphilitic ulcers on the patient's limbs showed signs of rapid healing, and on the fifth day they were covered with a thin layer of new cicatricial tissue. The pigmentation of the skin has disappeared in many places. The patient's appetite is better, and he feels stronger in every way. The remarkably sudden changes in his condition can only be attributed to the transfusion of blood. No medicine that I know of would produce them. Indeed, all the medicines he has been taking for the past six months have failed to benefit him.

The patient with phthisis whom I transfused with defibrinated blood by means of Colin's instrument, has had no bad symptoms whatever. There was no chill as in the previous case, nor was there any increase in the temperature or pulse. His temperature has not been above 99° F., and the pulse has averaged 90 beats per minute. It is now much stronger and fuller than before the operation. He says he feels strengthened in every way.

Now, I do not expect that the remarkable improvement which has taken place in these two cases will be kept up, unless transfusion is repeatedly performed. Both of them are afflicted with serious organic disease. Their blood-making and assimilating organs are working feebly, and furnish but little material to sustain their failing strength, and unless new life is given them by the introduction of fresh blood, the delicate machinery must soon cease working. To insure a successful issue, these patients should have the transfusion repeated once a week for the next six weeks. That is the only way that the fullest benefit can be derived from the operation. I doubt very much

whether they would consent to the necessary number of operations. They are willing to have transfusion performed once more. The syphilitic patient, however, wishes a respite of another week before it is repeated. The phthisical patient is willing to have it done at once.

I will defibrinate the blood as before, by whipping it for two or three minutes with a glass rod, straining it through linen, then whipping it again, and finally straining it through a piece of boiled satin into a glass dish containing a solution of ammonia. I was formerly of the opinion that, in the process of defibrination, the globular elements were diminished to such an extent as to impair the restorative qualities of the injected blood. Further investigation has convinced me that such is not the case, and you have seen here that as much improvement has followed the use of defibrinated blood as has occurred when the blood was undefibrinated.

The opening made last week in the left basilic vein has not yet healed. I will therefore open the vein in the corresponding arm and introduce the closed canula as before. The bowl of the instrument is now filled with blood and the tube attached to the canula in the arm.

Injection commenced; Dr. Stein noting the changes in the pulse.

Dr. Stein: The pulse is 84 and regular.

Prof. Howe: One cylinderful has been injected. How do you feel?

Patient: All right.

Dr. Stein: There is no change in the pulse.

Prof. Howe: There is now nearly two ounces of blood in. Do you feel any worse?

Patient: I have no bad feeling, except where the cut was made in my arm.

Dr. Stein: The pulse is not so frequent.

Prof. Howe: The cylinder of the instrument holds a little over half an ounce. I have thrown in two more, which makes over three ounces of blood added to the patient's circulation. How do you feel now?

Patient: I feel all right.

Dr. Stein: Pulse is stronger, and a little more rapid—88 per minute.

Prof. Howe: I have injected another ounce. The patient's respiratory movements are somewhat quicker. Have you any pain in your chest?

Patient: None whatever.

Prof. Howe: Have you any pain in your head, or any dizziness?

Patient: No sir; I feel all right.

Dr. Stein: The pulse is slower and quite regular.

Prof. Howe: He has now four ounces and a half of fresh blood. There have been no unfavorable symptoms in any stage or form. Can you get up without assistance?

Patient: Certainly I can.

Prof. Howe: All the changes following this operation will be carefully noted as before, and the results exhibited at our next meeting.

We have here another patient in the last stages of phthisis. She is twenty-four years old, and was perfectly well up to within three years of her admission to this hospital. She then contracted a severe cold, which settled on her lungs, and produced chronic inflammation at the apices. The lung tissue is breaking down rapidly. On the right side there is a cavity, and the whole lung seems to be involved in the destructive process. She is, as you see, very anæmic and emaciated. Her pulse is 110, and very feeble. Her temperature varies from 99° to 102° . To-day it is at the latter figure. ;

I will now show you the operation of transfusion with Aveling's instrument. This is a simple and comparatively cheap instrument. It consists of a rubber bulb, with a tube running off from each side. To the extremity of each tube is attached a silver canula—one with a bevel point and the other with a round point. The instrument is prepared for the operation by placing it in a basin of warm water, and alternately compressing and relaxing the bulb, until all the air is driven out and water drawn in to fill its place. The stop-cocks are then turned to retain the water in the tube. Having everything ready, I now distend the veins in the donor's arm by tying a bandage above the elbow and pinch up the integument over the median basilic vein, and incise it. Placing my thumb and forefinger at each end of the incision over the vein, I open the vessel a quarter of an inch. The canula, with the round extremity, is then passed into the vein from above downward, and held by the thumb and forefinger of an assistant. The vein in the patient's arm is opened in a similar manner, and the bevelled canula introduced. Now the bulb and tubes contain nothing but water. I compress the tube between the bulb and the arm of the donor, and then compressing the bulb, force the water into the vein of the patient. Before I relax my pressure on the bulb the tube near the arm of the patient is compressed. The bulb is then allowed to expand, and as it does so, the blood is drawn into it from the veins of the donor. When the bulb is filled with blood the same manœuvres are gone through with, until the necessary amount of blood is injected.

Now I have emptied the bulb nine times, and the tube has become clogged, so that no more can be injected. The bulb holds two drachms; so the patient has received sixteen drachms of blood and two drachms of water, scarcely enough to bring about any marked improvement in the patient. There have been no bad symptoms whatever during the injection, and I don't think any clots entered with the last portions of blood.

[The remainder of the hour was occupied by Prof. Howe in excising the shoulder joint of a patient suffering from long-standing arthritis.]

Saturday, Nov. 30th.—Michael Murphy, the patient with syphilis and phthisis, who was transfused with undefibrinated blood two weeks ago, was again presented. During the interval he had had a severe hemorrhage from the lungs, which, however, did not seem to weaken him. The operation of transfusion was repeated with Colin's instrument. Defibrinated blood, mixed with ammonia, was injected without a single unpleasant symptom developing either during or after the operation.

Wm. B. Mulcahy, æt. forty-eight, was next examined. He was suffering from tertiary syphilis and phthisis. Both lungs were extensively diseased. The liver was enlarged from waxy deposit. There was fluid in the abdominal cavity. The patient also suffered from profuse diarrhœa, which could not be controlled by medicines. He was exceedingly feeble, and unable to help himself in any way. Four ounces of undefibrinated blood were injected by means of Colin's instrument. Dr. Frankel, who noted the changes in the pulse, reported no unfavorable change during the operation.

H. B., æt. twenty-seven, was admitted to Charity Hospital March 19th, suffering from tertiary syphilis and phthisis. She was sinking rapidly when first examined, and there was every evidence that death would soon terminate her sufferings. Transfusion was performed Thursday, Dec. 5th. The instrument used was

a glass funnel, to which a rubber tube and canula had been attached. Nearly four ounces of defibrinated blood passed into the circulation. The pulse at the commencement went up to 160, but afterward fell to 130; temperature, 102°. No other change was noticed during the operation.

On Dec. 6th her pulse went down to 103; temperature fell to 99° F.

Dec. 11th she was in much better condition than before the operation, and is desirous of having it repeated.

On Dec. 11th, C. S., in a dying condition from syphilis and phthisis, was transfused with defibrinated blood by means of Colin's instrument. She was insensible when the operation was performed. Her pulse varied from 140 to 180, and was often imperceptible. Five ounces and a half of blood were injected without any further development of dangerous symptoms. A few minutes after the operation the pulse went down to 126, and the respiratory movements became more regular. The insensibility was also lessened. The improvement, however, did not continue, and death took place the next day, Dec. 12th.

Recapitulation.—We have had nine operations for transfusion performed during the past five weeks. All of the patients were suffering from advanced phthisis and syphilis. They were selected from the lowest and worst cases that enter Charity Hospital. They were all supposed to be beyond the reach of ordinary therapeutical measures. The first patient was transfused with milk (three and a half ounces). Symptoms indicating speedy dissolution developed during the operation. These subsequently disappeared, and some improvement in the general condition occurred, and continued for nearly two weeks. The patient did not wish the operation repeated. I could not find another who wished to try the milk. The second case was transfused with undefibrinated blood, mixed with ammonia. The operation was performed with the aspirator, which I had previously used in twelve cases. Dizziness, dimness of vision, and pain in the chest, with increased rapidity of the pulse, took place during the transfusion. Remarkable improvement followed. The syphilitic ulcers healed over, and strength and appetite returned. Two weeks afterward the operation was repeated on the same patient with Colin's instrument and defibrinated blood. The second operation was characterized by an entire absence of all the unfavorable symptoms which appeared when the aspirator was employed, and was followed by a corresponding progress toward a healthy state.

In the third case transfusion was performed *twice* with Colin's instrument, and defibrinated blood mixed with ammonia injected as in the previous case. No unfavorable symptoms developed during or after the operation. Marked improvement followed each transfusion, and the patient is still in excellent condition.

The fourth case was transfused with Aveling's instrument. Little or no improvement followed, because the quantity of blood injected was too small.

In the fifth case Colin's instrument was used as before on a patient in a moribund condition. There were no bad symptoms during or after the transfusion. Death occurred on the fourth day.

In the sixth case, defibrinated blood mixed with ammonia was used. The instrument employed was a glass funnel with rubber tube and canula attached. Patient is still improving.

The seventh patient was in articulo mortis when transfusion was performed. Five ounces and a half of defibrinated blood mixed with ammonia were injected with Colin's instrument. No bad symptoms

occurred from the operation. The improvement, however, did not last more than two hours, and death took place the following day.

Colin's instrument was used *six* times without any unfavorable symptoms attending the operation, and as much improvement occurred as when the defibrinated blood was used. I was somewhat surprised at this, because the first time I used the instrument in 1876 the symptoms were alarming and the operation had to be suspended. I think, however, that the blood in that case was not thoroughly defibrinated.

Judging from the results obtained during the present session, I am satisfied that transfusion of blood may be performed in the most extreme cases of exhaustion from excessive hemorrhage or organic disease without danger. The only thing necessary is to defibrinate the blood thoroughly and mix it with ammonia and inject it with Colin's instrument. Though I have not lost a patient from the use of my own instrument employed in thirteen cases, the symptoms exhibited have been often of such a startling nature that I feel justified in adopting for future use an operation which is free from these unfavorable symptoms, and at the same time one which is followed by equally good results.

An examination of the twenty cases transfused with blood by me during the past five years show that marked improvement followed the operation in eight cases, an improvement that could not be brought about by ordinary means. Improvement lasting but a few days occurred in seven cases. In *three* no beneficial change resulted, because faulty instruments were employed and the operation had to be suspended. One of the patients was in articulo mortis when the operation was performed, but even in this one, change for the better occurred. One made a complete recovery.

If we carefully compare the results of transfusion of blood with the results obtained from transfusion of milk, it will be readily seen that the symptoms developed during the latter operation indicate greater danger to life than those which are witnessed in the former, and that much more improvement follows the injection of blood than has ever been brought about by the intravenous injection of milk. Some of the improvement which took place in the cases reported by Prof. T. G. Thomas, of this city, and Dr. Charles Hunter, of Philadelphia, was undoubtedly due to stimulants administered during and after the operation. Brandy and ammonia were administered freely to some of Dr. Thomas's patients, and quinine in twenty-grain doses to Dr. Hunter's. These powerful remedies could not but induce an increase in the vital forces. It would not be reasonable, under the circumstances, to attribute the favorable change solely to the milk. Milk in the circulation is a foreign material, and though it is possible that the milk globules may ultimately be converted into blood-globules, yet the period of conversion would be so great as to preclude the probability of an immediate restorative effect. In this connection I may mention that Dr. Prout, of Brooklyn, in a communication to the *MEDICAL RECORD*, May 11, 1878, gives some interesting experiments in milk transfusion made by Dr. Wulfsberg, of Göttingen. Dr. W. found that a few hours after the injection of milk, the milk globules became enclosed in a colorless blood-corpuscle, and that ultimately the number of these colorless globules became very much increased. Dr. W. considers the intravenous injection of milk a dangerous operation unless the quantity employed is very small.

There is no doubt in my mind that the intrave-

nous injection of milk is a dangerous operation, and one that should only be resorted to when blood cannot be obtained. Blood is the natural vitalizing element of the tissues, and with the precautions which I have pointed out, may be injected into the veins in all cases of acute anemia, and excessive exhaustion from organic disease, without any danger to the patient.

Original Communications.

A CONTRIBUTION TO THE MEDICINAL TREATMENT OF CHRONIC TRIGEMINAL NEURALGIA.

By E. C. SEGUIN, M.D.,

NEW YORK.

(Read before the New York Neurological Society.)

HAVING recently met with three cases of severe chronic cases of neuralgia of the trigeminus which have been favorably influenced by the internal administration of medicines, I have requested the privilege of presenting a report upon them to the Society.

CASE I.—Epileptiform neuralgia of thirteen years' standing: cure.—J. W., a farmer, aged 63 years, presented himself at my clinic for Diseases of the Nervous System on or about June 15, 1878, and gave the following history: Has suffered from neuralgia in the right side of the face for thirteen years. The first pain, slight and stinging, made its appearance near the external angular process of the frontal bone. There was a gradual increase in the frequency of the paroxysms, and in the severity of the pain until the time of examination. During three years has had almost constant pain, *i. e.*, the paroxysms have been repeated every two or three minutes. There has been much pain at night, but the greatest suffering has always been experienced in the forenoon. The seat of neuralgia has been the right malar region and the lower anterior temporal region. Paroxysms have been excited by the contact of clothing or of the finger; by talking or eating, and by pulling the hair on the lip and cheek. The pain has never been periodical.

The patient's general health has always been good; he has had two attacks of malarial fever; one when a boy, the last six years ago. When the attack began he was living in Marlboro, Ulster Co., N. Y., considered a healthy place. Has never had syphilis; has always been temperate.

Attack witnessed at the clinic: A sharp and exceedingly severe pain appears in the region defined above, accompanied by injection of the cheek and eye, and the escape of tears. The paroxysm lasts several seconds, and returns every two or three minutes. Nitrite of amyl seems to mitigate the suffering. Examination of the affected and of adjacent parts is negative; there is no anesthesia or true tender points, or any exciting cause of pain within the mouth. The etiology of the affection is unknown.

Treatment.—From June 17th to 21st, hypodermic injections of Squibb's chloroform were made daily through the mucous membrane of the cheek toward the malar region, from one to ten minims being used each time. In making these injections care was taken to avoid the point of exit of the infra-orbital nerve. The last injection was made near the supra-orbital nerve. These injections produced some smarting pain and secured relief for several hours each day, but did

no more; the pain returning the next day as severely as before. Some bad effects were, however, produced, and these are worthy of consideration because hypodermic injections of chloroform in the face are usually considered harmless. I observed in this case some swelling at the seat of injection, paresis of the lower facial muscles of the type produced by lesions of the cerebral hemispheres; there was also marked numbness and slight anaesthesia in the skin of the cheek near the angle of the mouth, and over the eyebrow. The electro-muscular reactions remained normal, no abscess followed, and the paresis gradually passed away. I might add that similar unpleasant results ensued in another case in my practice about a year ago.

On June 26th, 27th, 28th, daily injections of Fowler's solution (diluted one-half) were made in the affected cheek through the mucous membrane without good or bad effects.

From June 21st to 26th, I tried Thompson's solution of phosphorus, in doses of one teaspoonful ($=\frac{1}{15}$ gr.) three and four times a day without marked benefit.

Still, on the whole, at the end of June, the patient was somewhat improved, having severe paroxysms only from four to ten times a day; though slight, sharp pains were still very frequent.

About the end of June he was given iodide of potassium in gradually increasing doses of a saturated solution. He began with ten drops three times a day, and by an increase of five drops per day at each dose, he attained a maximum of ninety-five drops three times a day. No evident benefit resulted from this course, which was terminated on July 12th.

On July 13th, was ordered five drops of the fluid extract of gelseminum four times a day. July 15th.—Reports himself as very much relieved; no special symptoms have been produced by the drug; is directed to take eight drops four times daily. July 16th.—Yesterday had no paroxysm except while eating;—there have been frequent but bearable "ticks" of pain in the vicinity of the right external angular process of the frontal bone. Is ordered to take ten drops four times a day.

August 1st.—About this time, as the patient could no longer stay in town, and as I was unwilling to let him take gelseminum while away from observation, the solution of iodide of potassium was again given in doses of sixty drops three times a day.

August 10th.—Patient returns to town, and reports himself no better; he has taken the medicine regularly, and has kept a journal of the attacks. The number of attacks per diem, usually excited by eating, etc., have varied from four to eight. The iodide is suspended. The actual platinum cautery is gently applied over the right malar and temporal regions, and five drops of Fowler's solution are given in water three times a day, to be gradually increased. August 20th, the diary shows a decrease in the number and in the severity of the pains; only from three to five paroxysms each day; three yesterday. Has been cauterized three times.

August 22d.—About this time the neuralgia ceased altogether, the dose of Fowler's solution being ten drops three times daily.

September 22d.—Patient has had no pain since the last note—a period of thirty-two days. Absolutely no pain has been felt, and the hyperaesthesia has disappeared; patient can eat, talk, wash, or rub his face with impunity for the first time in many years. The paresis of the lower face, produced by the injections of chloroform, has nearly passed away, and there is no more numbness. No toxic effects have been caused by the arsenic; but, as he has taken ten drops so long, a

change is made to Thompson's solution of phosphorus, one teaspoonful three times a day.

On September 24th a few slight paroxysms occurred, and the patient, of his own accord, resumed the arsenical solution in full doses, and in a day or two the pains ceased, and they have not returned.

Early in November this patient was shown at my clinic. He then asserted that he was perfectly well, and his healthy and cheerful aspect confirmed his statement. As he has not returned, I feel reasonably sure that the good result has been permanent.*

CASE II.—*Epileptiform trigeminal neuralgia of ten years' standing greatly relieved by treatment.*—H. S., aged 29 years, a janitor by occupation, consulted me on October 2, 1878, and gave the following history: Previous to the development of the present affection he had been subject to occasional dull headaches. Ten years ago he suddenly experienced a very severe sharp pain all through his head, "as if devils were at work there," lasting half an hour. There was no dizziness, or nausea, or faintness, or impairment of sight, or paralysis. For a period of six months he remained free from pain, and, indeed, was perfectly well; then a "dull, stupid pain" began over the right eye, extending from the supra-orbital notch inward to the nose, and down the side of the nose to the ala. This pain was paroxysmal, and worse in the day-time. Later the pain extended to the eyeball, and was exceedingly severe; the paroxysms recurring from ten to twelve times a day. In the course of two or three years pain made its appearance in the right temple, worse at night.

In the last few years the most pain has been on the top of the head, above the temple, and in front of the ear to the bregma. There has lately been an occasional and rare pain in the nose; not much in the temple. During the past summer and since, there has been some occipital pain on both sides, more on the right. In the last year there has also been pain in both jaws, in the upper lip near the median line; none in the tongue. In the last four years vision has been dim, and glasses have not corrected this defect. Five years ago, while taking medicine, had temporary diplopia. At various times during this long illness has had "dizzy spells" with varying frequency; seldom in the last few months. Has had no symptoms in other parts of the body; memory is impaired; the virile power quite lost. Had severe dyspepsia and vomiting three years ago, and has been costive during the whole period of the disease. The various painful regions are hyperaesthetic, but not numb, and the tactile sensibility is perfectly preserved on both sides. There is no facial paralysis; the right pupil is positively small, the left normal. After dilatation by atropine, the ophthalmoscope shows nothing abnormal in the bottom of the eye. Hearing, smell, and taste are normal. The urine has been frequently examined by physicians and always found normal; it is now free from albumen. Marked anæmia is present in the skin and mucous membranes; has always been pale.

The paroxysms of pain are the most terrible which I have ever witnessed; the patient fairly writhing in his chair or falling to the floor in his agony. During the attack the right eye is very much injected and waters.

The patient states that no medicine has ever relieved him, and he has tried a great many. I at once prescribed Duquesnel's crystallized aconitia, a remedy

* A letter from this patient's wife, received about December 10th, states that he remains well.

with which I had obtained remarkable results during the year. The prescription was:

R. Aconitiæ (Duquesnel's)..... gr. $\frac{1}{4}$
 Alcoholis,
 Glycerinæ, aa..... $\frac{3}{4}$ i.
 Aq. menthæ pip. ad..... $\frac{3}{4}$ ij.
 M.

S.—A teaspoonful three times a day between meals.

I also gave him one teaspoonful of Wyeth's dialyzed iron every evening at bed-time.

Oct. 3d.—Has severe paroxysms every day; seven on October 3d, and nine yesterday.

Oct. 11th.—Has only slight physiological effects (numbness) in the finger-tips; from six to nine attacks each day. Now takes $\frac{1}{10}$ gr. aconitia three times a day.

Oct. 14th.—On the 12th had twelve severe spells; only two yesterday. He yesterday took, by mistake, 3 ij. of aconitia solution, or $\frac{1}{10}$ gr., twice, and two doses of 3 i., and this morning 3 ij. This is the equivalent of $\frac{1}{10}$ gr. of aconitia in twenty-four hours. He is very nervous, feels as if electricity were passing through his body and limbs; he "cannot contain himself." As this was a mistake, I directed him to resume the prescribed doses of 3 iss. ter die. The results of this mistake were, however, most fortunate; improvement began from this strong impression of aconitia upon the system, as shown in the tabular record of paroxysms:

Oct. 19th.—Excellent record; since October 13th has had only from one to three severe attacks; ordered to continue aconitia and to begin a saturated solution of iodide of potassium in five drop doses.

Oct. 31st.—Continues to do well, *i. e.*, has from one to two or three severe paroxysms daily, and a number of slight twinges. Feels numb and "very cold" from three doses of aconitia. Can't be warmed even by an overcoat; general condition much improved; physiognomy calm and contented. Besides aconitia, takes twenty-eight drops of solution of potash.

Nov. 30th.—Improvement maintained. Passes some days without severe attacks, and a few with no pain at all. Has done much of his work as janitor of late. The aconitia has lately (since 23d) been taken twice a day, and has hardly any numbness.

On Dec. 19.—Pills of arsenic $\frac{1}{15}$ gr., quinia gr. iii., and belladonna $\frac{1}{2}$ gr., were substituted for the iodide of potassium. The iron is kept up at night, 3 i. of dialyzed iron.

CASE III.—*Neuralgia of Right Inferior Maxillary Nerve of eight years' duration; cure.*—Observed at the College of Physicians and Surgeons. Mrs. A. D., aged fifty-seven; was first seen at clinic for diseases of the nervous system in the autumn of 1874. She gave the following history: In 1870 had trouble with the teeth in the right lower jaw, "caught cold in the gums," and the present pain began. It occurred in paroxysms of sharp, severe pains in the right lower jaw, right half of tongue, and right half of lower lip. She suffered with no intermission up to the time when Dr. D. M. Stimson sent her to the college. The medicinal treatment which I then advised had no more effect on the neuralgia than others which had been tried, including extraction of the teeth.

In the succeeding summer, 1875, Mrs. D. again came to see me, representing herself as under no physician's care. I accordingly took charge of her, and excised at least one-quarter of an inch of her infra-maxillary nerve by the intra-buccal method, also known as Lizars'.

This was followed by absolute cessation of all pain in lip, tongue, and jaw, and by anæsthesia of the right half of the lower lip.

In a few weeks—patient thinks three or four—some return of sensibility occurred in the anæsthetic district, and has increased until now; even delicate tests reveal no anæsthesia. No pain recurred until the early spring of 1877, a period of twenty months. In April, 1877, patient's husband died, and she sat a long time near the ice-box in which his body was preserved. Immediately had a return of neuralgic pain in the same regions, viz., tongue, gum, and lower lip of right side. The pain was again sharp and paroxysmal. She suffered greatly until late in the autumn of 1877, when spontaneous relief took place, and she had pain only at intervals during the whole winter. The only medicine which she took during this time was cod-liver oil. She had no powerful drugs. In the spring and early summer of this year she had as frequent and as severe attacks of pain as at any time; many paroxysms each day, attacks epileptiform in suddenness of appearance and in severity. She presented herself at the Clinic for Diseases of the Nervous System for the third time, in July 13, 1878, and the following notes from the clinic case-book embrace her history since that date:

July 15th.—The pain begins in the gum of the right lower jaw, then darts into the right half of tongue along its whole length, especially in its anterior portions; it also affects the right half of the lower lip. She has no pain in the upper jaw or in the distribution of first branch of trigeminus, but it should be stated that she has a good deal of pain, also neuralgic in character, in the right side of the head behind the ear, the right side of the neck, and right shoulder. From almost the commencement of her illness, more or less of this pain has existed, varying greatly at times, but not annoying so much by far as the maxillary neuralgia. The paroxysms of pain in the jaw and tongue come on every few minutes. Once in a while, the patient adds, when the pain is greatest in the above described region, a little of it shows itself in the gum of the right upper jaw. Is ordered a tonic mixture.

July 20th.—Is better, generally, than last week. Ordered extract gelsemini fld., gtt. v., t. i. d., the dose to be increased by one drop each day.

July 27th.—Pain relieved by the gelseminum, gtt. viij. of which produced queer sensations and double vision. In the last few days has taken only gtt. vi., t. i. d. Ordered gtt. v. twice a day and gtt. x. at bed-time.

August 3d.—No marked benefit from above treatment, although much distress was produced by doses. Ordered $\frac{1}{40}$ grain of Duquesnel's aconitia in solution t. i. d.

August 10th.—On the 7th reported at my office, and as the above doses had produced no effect, I directed her to take $\frac{1}{60}$ grain t. i. d. on an empty stomach. To-day (three days after beginning the larger doses) she is free from neuralgic pain, though some soreness of the parts remains. After each dose of $\frac{1}{60}$ grain had some tingling in extremities and face. Treatment to be continued.

August 31st.—Has had no paroxysm of pain since beginning the $\frac{1}{60}$ grain dose. Has only noticed an occasional soreness in the tongue, provoked especially by acids. Can eat with comfort, whereas four weeks ago attempts at mastication caused agony. States that effects of one dose of aconitia consist in tingling in the whole body, most marked in the toes and fingers, and in peculiar chilly sensations.

The pain in the neck and shoulders is not wholly relieved. Complaints of much sweating at nights. To take for two or three days one ten-grain dose of sulphate of quinia at bedtime. The aconitia to be omitted, and Fowler's solution to be taken instead, in doses of gtt. iij. after meals, gradually increased.

September 14th.—Has remained perfectly free from facial neuralgia, and has had only moderate pain inside of neck, right shoulder, and upper arm. Has taken gtt. x. of Fowler's solution without unpleasant effects; sweating arrested. Ordered to cease taking arsenic, and to use ʒi. of Thompson's solution of phosphorus (= $\frac{1}{19}$ grain of phosphorus), night and morning.

September 21st.—Had slight return of pain in right lower jaw and tongue on September 18th and 19th; arrested by a few doses of aconitia. To-day is perfectly well, except that right side of neck and arm are painful.

October 11th.—Has had no return of neuralgia since last note, and neck has not been so painful. States that she has more or less pain in the whole right side from behind the ear to arms and down lower extremity to heel at times. With exception of slight neuralgic pains on September 18th and 19th, has had no recurrence of inferior maxillary or lingual neuralgia since August 7th, a period of sixty-five days.

It seems to me that three conclusions may legitimately be drawn from the above related cases:

1. That there is a possibility of relief in most severe cases of epileptiform trigeminal neuralgia. The usually received opinion is that, in such cases, recourse must be had to operation upon deep branches of the nerve, excision of Meckel's ganglion, etc., and to the systematic use of morphia to make life endurable. After my experience with the above cases, I am disposed to urge a sufferer from trigeminal neuralgia to make a trial of medicinal treatment.

2. The advantage of using medicines systematically. Not only should the doses of any one remedy be administered regularly and in progressively increasing doses, but several remedies may be used in succession, so as to profoundly affect the system. Of the medicines applicable for the treatment of neuralgia, the following are those which I can recommend most highly: aconitia, arsenic, iodide of potassium, gelsemium, belladonna, quinia, morphia, galvanism, the actual cautery, Thompson's solution of phosphorus.

3. In the treatment of chronic neuralgia and of many neuroses, it is necessary to obtain the physiological effects of the drug employed, in order to do good. This principle of heroic medication is one which ensures success in seemingly desperate cases, and its execution requires the utmost watchfulness on the part of the physician, and intelligence and faithfulness on the part of the patient and his attendants. Many unpleasant consequences of such treatment may be avoided if we at first give very small doses of the remedy, and then make a very progressive increase. The good effects of giving medicines to the production of physiological effects are illustrated in the above cases; in the treatment of chorea by arsenic; of malarial affections by quinia; of spinal congestion and myelitis by belladonna; of syphilitic disease by mercury and iodide of potassium, etc., etc.

Inasmuch as the good effects noted in Cases II. and III. were obtained by the action of Duquesnel's aconitia, it may not be amiss to close this short communication by quoting the conclusions of a report on

aconitia recently made to the N. Y. Therapeutical Society by its Committee on Neurotics.*

The chairman of this committee says:

"From the above cases the following conclusions may be justly drawn, I think:

1. The susceptibility of individuals to Duquesnel's aconitia varies enormously; one individual in the series having been severely affected by $\frac{1}{200}$ grain, while another tolerated with no special symptoms $\frac{1}{10}$ grain every three hours. On the average, distinct physiological and therapeutical effects were obtained by giving $\frac{1}{100}$ grain three times a day.

2. Out of six cases of severe trigeminal neuralgia, one, probably a reflex neuralgia from a decayed tooth, was not at all benefited.

Three cases, epileptiform in character, were slightly or only temporarily relieved. Two cases were cured. One of these had existed for seven years, with an interruption of twenty months, procured by resection of the affected nerve.

It would thus appear that, while we cannot indorse Prof. Gubler's statement that Duquesnel's aconitia never fails, we must recognize in it one of the most powerful and best agents for relieving and curing trigeminal neuralgia.

3. We do not as yet know the forms of trigeminal neuralgia which can be most influenced by aconitia."

MEDIO-LATERAL LITHOTOMY, IN A COMPLICATED CASE OF VESICAL CALCULUS.

By JOHN A. WYETH, M.D.,

NEW YORK.

A GENTLEMAN, aged 53, a native of Bermuda, was sent me by my friend Dr. John H. Arton, practising in that island. Several years ago he had suffered from renal colic, and a few days afterwards had passed by the urethra two small stones, about one-quarter of an inch each in diameter. These I found to be phosphates. In 1876 symptoms of vesical irritation appeared, which increased until, in November, 1878, he was forced to seek relief by an operation. Upon sounding him, a stone was detected, not in the fundus, but seemingly caught in a pocket just behind the pubic symphysis, well above the urethral opening of the bladder. Its size could not be accurately estimated by the sound, owing to its being touched on only one side. After consulting with my friends, Prof. F. H. Hamilton and Dr. E. A. Banks, after a preparatory course of treatment for ten days, it was determined to attempt lithotripsy under ether, and, this failing or being deemed impracticable, to resort to lithotomy. With the assistance of these gentlemen, and of Drs. Russel, Irquhart, Wardwell, and Wilkinson, I introduced a Thompson's lithotrite, and, after the most patient and persistent effort, it was found impossible to engage the stone in the jaws of the instrument. Upon sweeping the floor of the bladder with the convex surface of the lithotrite, the stone could not be felt; but, by depressing the handle well towards the coccyx, the tip of closed blades could be felt to strike the calculus, which was rough; but, although the bladder contained about five ounces of water, and the blades were carefully separated to as much as two inches, and were felt grating against the stone, it could not be firmly engaged between them. There was left the *dernier ressort* of cutting.

* *Vide* N. Y. Medical Journal, Dec., 1878, p. 621.

and the median operation was performed. Upon introducing the finger to dilate the prostatic urethra, the stone was discovered well up behind the pubis, caught in a vesical pouch, in which it was crushed by the large forceps, and the pieces were scraped out with considerable difficulty. This part of the procedure, owing to the large size of the stone, and immense number of fragments, was so tedious that, before it could be completed, owing to threatened collapse on the part of the patient, it was discontinued temporarily. He rallied quite well in the course of ten or twelve hours, passed his urine through the wound and urethra simultaneously, and, in addition, through the wound, some small pieces of stone. Three days later, the temperature being only 100° F., and condition otherwise good, the wound was enlarged laterally, under an anæsthetic, and the remaining fragments removed, the bladder thoroughly washed, and a large drainage-tube left in the bladder. Putting the pieces together, the calculus measured two inches in diameter, and was almost round—the fragments, which were preserved, weighing 624 grains (troy). The patient vomited while the effects of the ether were passing off, and this gastric intolerance continued to such an extent that no aliment could be retained in the stomach. Enemata were regularly given every few hours, and fifteen grains of quinine hypodermically each day, and, although the temperature at no time reached more than 101½, the patient died of exhaustion due to gastric intolerance, eight days after the last operation. The wound was doing nicely, the drainage was free and uninterrupted, and there was no symptom of pyæmia or peritonitis, and no complaint of suffering other than the extreme nausea. An autopsy was not obtained. An autemortem examination of the urine showed no signs of renal disease.

Reports of Hospitals.

THROAT CLINIC AT CHARITY HOSPITAL, B. I.

SERVICE OF DR. ELSBERG.

(Reported by C. C. RICE, M.D., Resident Physician.)

1.

THE LARYNX IN CASES OF LEPROSY (ELEPHANTIASIS GRECORUM).

VERY few laryngoscopic examinations of leprosy patients have hitherto been reported. Indeed, in this country, the disease itself is so rarely met with that every contribution to its statistics is of some value.

CASE I.—Emilio Trenal, æt. 19; single; native of Santiago, Cuba; admitted to hospital June 21, 1878. The patient is a bright, intelligent boy. He knows very little about his parents, as they died when he was quite young. He lived in Cuba until he was nine years of age, and has been in New York since. Nothing definite as regards hereditary taint could be learned. He thinks his mother had white spots on her face, similar to the cicatrices on his own body, but never heard that she had leprosy. She died of cholera. His father died of yellow fever. He never saw any one suffering from this disease until the admission of the other patient (Case II.) in July, 1878. His general health has always been good. He describes very accurately premonitory symptoms, which he ex-

perienced four years ago; they correspond to those spoken of by Duhring,* such as malaise, sleepiness, headache, chills and fever, and pains in bones. These continued with varying intensity for a year before he noticed any manifestation of the disease. First, two red spots, and then, on the same places, hard, brownish red lumps showed themselves on his left cheek near the nose, and the neighboring tissue became somewhat indurated. The disease seems to have made but very little progress for two years. In June, 1876, he had an acute attack of rheumatism, and was admitted to Charity Hospital as a patient. He was told at this time by the visiting physician that he had leprosy. He received some medication, and the tubers decreased in size, leaving brownish white cicatrices. In July, 1877, new indications of the disease appeared. The lower portions of the forehead became hard and brawny; a little later the surface was raised into tuberculous masses. These tuberosities range in size from that of a cent to that of a silver dollar. They are hard and involve the skin, which cannot be moved above the mass. Some of them seem to be an aggregation of smaller ones, but as a rule they are arranged singly. Their outline is quite well defined, and they are surrounded by healthy tissues. His eyebrows came out. His hair, which was formerly black, turned to a dingy brown. The eruption gradually spread over the lower portion of the face, involving especially the nose, lips, chin, and cheeks. The ears were only slightly affected. The overhanging eyebrows, the large nose studded with tuberculous excrescences, and the cheeks and chin thrown into rough and uneven appearing ridges, all help to give the patient the peculiar expression of the face called "leontiasis." There is nothing on the body but a few white scars, which were formerly dark macule. The forearms and legs have become much darker, and are covered with brawny scales, which desquamate constantly. There are only three points of ulceration on the body, two on the calf of the right leg and one on the inner side of the left thigh. These are not at all painful, and there seems to be more or less anæsthesia of the upper and lower extremities, though he thinks his face is rather more sensitive than in health. During the last year he has noticed a gradual change in his voice. He has always been fond of music, and sang a high tenor; now he speaks in a peculiarly husky or muffled tone, and, when he attempts to reach a high note or sing softly, he finds that he is not able to make any sound. He is obliged to constantly clear his throat, and he suffers a little from dyspnoea after exertion. He has no difficulty in deglutition, but in drinking water he is relieved by pressing on his thyroid cartilage. When examined with the laryngoscope by Dr. Elsberg, it was found that the air-passages have undergone changes similar to those on the face. All the portions of the mouth and throat rich in loose connective and adipose tissues are more or less involved, while, where the mucous membrane is attached more closely to the harder structures beneath, it is intact. The tongue is large, swollen, and fissured, but there are no ulcerations. The uvula is long, and the surface made uneven by the presence of several small tubers. With the exception of some hyperæmia and hyper-secretion, there are no pathological changes on either the hard or soft palate or the pharynx. The laryngoscope revealed a large, thick, congested epiglottis (Fig. 1.) Its free margin had lost its symmetry, and seemed to be carried backward over the larynx by the weight of the tuberculous masses, which

* A Practical Treatise on Diseases of the Skin, by Louis A. Duhring, M.D., Philadelphia, 1877, page 432.

covered it so that only its lingual surface could be seen. Such masses were on each side of the frenum and extended forward toward the tongue. Only the arytenoid cartilages and parts of the vocal bands appeared in the mirror when the epiglottis was slightly raised during forced inspiration. To see all the parts required a number of views and various manœuvres. The upper aperture of the larynx has become irregular

FIG. 1.

and altogether smaller. The ary-epiglottic folds are tumefied and studded sparingly with small tubers. The ventricular folds present the same swollen and congested appearance, with a number of tuberosities, and partially cover the vocal bands, so that during phonation only the inner edges of the latter can be seen. These are white and glistening. The mucous membrane covering the arytenoid cartilages is greatly swollen and dark-red in color. Two tubers of somewhat larger size are on the right arytenoid and one on the left. The parts move sluggishly during phonation. The mucous membrane of the larynx and surrounding parts hypersecretes. The patient's general health is fair; he suffers considerably from mental anxiety. His appetite is good. He has no pulmonary or cardiac trouble, and the kidneys seem to be in a normal condition.

CASE II.—Abraham Brown, aged forty-five; native of New York; bricklayer; admitted July 5, 1878.

His family history is excellent. Nothing of importance, or that relates in any way to his present disease, can be stated of patient up to his thirty-second year. His habits were good, and he worked in New York at his trade as a mason until of that age. He then went to Santiago, Cuba, and remained three years. He returned to New York, and has lived there since. Like Trenal, he never had seen a case of leprosy until he came to the hospital. He noticed nothing in regard to himself until one month before the eruption appeared on his face. The prodromata in this case were somewhat similar to the other. He also had frequent chills, and was considerably troubled with drowsiness and languor; but these were not severe enough to prevent his working. In March, 1878, the face became covered with tubers, and now presents a more characteristic appearance of the disease than the other case. The lumps are somewhat larger than those upon Trenal's face, but their physical character is very similar. The eyebrows are quite prominent, and give to the patient a very savage appearance. The nose, chin, and lips are like Trenal's, but the lobules of the ears are very much enlarged, and hang down like immense ear-rings. The whole face has become much darker. The body for the most part has preserved its integrity. The legs and arms are brownish-red, and covered with fine scales. The disease has gone on to ulceration on the fingers and toes. Hands and feet are swollen, the two last phalanges covered with bad-looking sores, which discharge very little, and are only slightly painful. The nails have almost entirely disappeared, except those

upon the great toes, and they are already loose and will soon be gone. The mouth and pharynx have not escaped. The tongue is so thick that the patient speaks like a drunken man, and saliva dribbles from his mouth. The gums are red and somewhat swollen, but there is no ulceration; the tonsils seem to be very slightly affected. The palato-glossal and palato-pharyngeal folds have been ulcerated through and become adherent in several places. The inner side of the cheeks and posterior wall of the pharynx are dotted with small papillary excrescences; there is one large ulcer on the hard palate. The patient has ozenic catarrh, and although the pituitary membrane seems to be injected, none of the tuberosities are apparent in either the nasal organ or pharyngo-nasal space. The epiglottis is considerably tumefied, its free edge thick and irregular, with angular lateral boundaries. (Fig. 2.) It hangs heavily back over the larynx, and seems to have lost its elasticity. The ary-epiglottic folds and the ventricular bands are enlarged, congested, and uneven, covered with a few large and many smaller tubers. The lumps partially hide and give to the arytenoid cartilages an ill-defined and shapeless appearance. The posterior halves of the vocal bands are masked beneath this new growth.

FIG. 2.

Two large lumps are seen, the one anterior and the other posterior to the left arytenoid, on its inner side. The right arytenoid, although involved throughout its whole extent, has no tuberosities which rise above the general level and which are sharply defined. There is less swelling about the anterior half of the rima glottidis, and the vocal bands can be seen to approach each other during phonation. They are of a dirty yellow color. In the inter-arytenoid space one large tuber stands out prominently into the larynx.

The general condition of the patient is not as favorable as that of Trenal.

The accompanying drawings were made by Dr. H. Levy, Assistant House-Physician.

Professor Elsberg made some additional remarks on laryngeal leprosy. He said that the systemic cachexia which constitutes the disease, as manifested in the skin, nerves, etc., as well as on mucous membranes, is not sufficiently understood to enable us to speak positively as to its nature.

"*Lepra arabum*" and "*elephantiasis græcorum*" are equivalent designations for leprosy, but "*elephantiasis arabum*" and "*lepra græcorum*," though sometimes confounded, are names for two diseases differing from each other and from leprosy. *Elephantiasis arabum* is a hypertrophy of the skin and subcutaneous (sometimes also submucous) connective tissue, while *lepra græcorum* is a scaly skin disease, a variety of psoriasis.

The laryngeal disease occurs in all, or nearly all, cases of leprosy. It appears secondarily in time to the cutaneous, although occasionally the latter is for a time so slight, in comparison with the affection of the

mouth, throat, and larynx, that this assumes prominence. At the present day, leprosy occurs almost exclusively in certain countries, chiefly tropical, or in persons who have visited or resided for a longer or shorter time in such countries.

Topographical circumstances have most to do with the affection. Although its cause is shrouded in mystery, climatic agencies, including noxious soil, environment, habitation, food, and other local (endemic) or personal unhygienic influences are recognized as producing the disease. Hereditary predisposition exerts considerable effect; but it is not contagious.

The three types or forms recognized in the skin affection—*lepra maculosa*, spotted leprosy, *lepra tuberosa*, lumpy leprosy, and *lepra anæsthetica seu mutilans*, anæsthetic or mutilating leprosy—usually occur as stages merely in the laryngeal disease. The first pathological change noticeable is vascular injection; the vessels become very visible, the veins are varicose, then, on spots ordinarily small, but sometimes large, the epithelium is found lost, and in places more or less deep infiltration occurs; hypersecretion is present in almost every case. The infiltrated masses may be seen to be covered with a thick layer of epithelium, of which they are easily deprived, and which is as easily regenerated. These lumps, though at first sometimes very firm, have a decided inclination to ulceration; but the destructive process does not usually involve more deep-seated structures. Form-changes of various parts of the larynx occur from the infiltration, later from ulceration, and then from cicatrization. The lumen of the upper aperture is almost always interfered with, and, in the progress of the case, stenosis, possibly sometimes to a dangerous and fatal extent, is sure to take place.

By the aid of the laryngoscope, it is usually easy to determine whether and to what extent the larynx is affected in a case of leprosy. At first, dilated blood-vessels are seen on the epiglottis, with a peculiar reddish-yellow appearance of the interior of the larynx; then, frequently, gray or dirty discoloration of the vocal bands; and later on, with increased vascularization, the lumps and ulcers. The latter are readily distinguished, from their peculiar appearance and localization, from laryngeal carcinomatous granulations and ulcerations. The diseases which produce similar appearances are lupus, syphilis, and phthisis. The clinical history, and especially the cutaneous and other manifestations generally, make a differential diagnosis between these and laryngeal leprosy a matter of no great difficulty. The intense vascular injection is absent in phthisis, and Dr. Elsberg prefers to avoid the term tubercle, which has come to be identified with phthisis, when designating the lumps or tubers of leprosy.

The peculiarly husky voice of lepers was well known in the Middle Ages,* and constituted an important sign in the *inspectio leprosum*. Dyspnœa also occurs in the course of the disease, but cough and pain in the region of the larynx very seldom; there is more or less anæsthesia, and the introduction of instruments produces no reaction. Deglutition is sometimes affected; but this, too, is comparatively slight and disproportionate to the destruction that may take place in the upper part of the larynx and the lower portion of the pharynx. The prognosis of laryngeal leprosy is always unfavorable. The voice cannot be restored, even though life may not be destroyed by the disease of the larynx.

In addition to the other therapeutic and particularly hygienic measures to be adopted in the case of leprosy patients, the condition of the larynx requires cleansing spray and soothing local inhalations. A diluted emulsion of gurjun oil (balsam dipterocarpi) has of late years been praised very highly as a local as well as internal remedy in leprosy. Applications of saturated solution of iodoform in sulphuric ether have proved grateful. To prevent death from laryngeal stenosis, tracheotomy should be performed, but it has not been called for in any case within Dr. Elsberg's knowledge.

Progress of Medical Science.

MEMBRANOUS CROUP AND DIPHThERIA.—At a recent meeting of the Royal Medical and Chirurgical Society, Dr. Andrews presented the report of the committee appointed to examine into the relations existing between these two diseases. The following are the conclusions arrived at: 1. Membranous inflammation confined to or chiefly affecting the larynx or trachea may arise from a variety of causes, as follows: (a), from the diphtheritic contagion; (b), by means of foul water, of foul air, or other agents, such as are commonly concerned in the generation or transmission of zymotic diseases; (c), as an accompaniment of measles, scarlatina, or typhoid, independently of any ascertainable exposure to the especial diphtheritic infection; (d), it is stated, on apparently conclusive evidence, that membranous inflammation of the larynx and trachea may be produced by various accidental sources of irritation—the inhalation of hot water or steam, the contact of acids, the pressure of a foreign body in the larynx, and a cut throat. 2. There is evidence in cases which have fallen under the observation of members of the committee, that membranous affections of the larynx and trachea have shortly followed exposure to cold, but their knowledge of the individual cases is not sufficient to exclude the possible intervention or coexistence of other causes. The majority of cases of croupal symptoms directly traceable to cold appear to be of the nature of laryngeal catarrh. 3. Membranous inflammation, chiefly of the larynx and trachea, to which the name "membranous croup" would commonly be applied, may be imparted by an influence, epidemic or of other sort, which in other persons has produced pharyngeal diphtheria. 4. And, conversely, a person suffering with the membranous affection, chiefly of the air-passages, such as would commonly be termed membranous croup, may communicate to another a membranous condition, limited to the pharynx and tonsils, which will be commonly regarded as diphtheritic. It will thus be seen that, in the opinion of the committee, these two diseases are identical. It is suggested that the term "croup" be henceforth used wholly as a clinical definition, implying laryngeal obstruction, occurring with febrile symptoms in children, which may be membranous or not membranous, due to diphtheria or not so. The term "diphtheria" is the anatomical definition of a zymotic disease, which may or may not be attended with croup. It is admitted, however, that when obviously occurring from a zymotic cause or distinct infection, and primarily affecting the pharynx, constitutional depression is more marked, and albuminuria is more often and more largely present, though in both conditions some albumen in the urine is more frequently present than ab-

* Says HANS VON GERSDORF, in his *Feldbuch der Wundarznei*, 1536: "Das erst zeichen ist die heysere in der stym und red, edge des otems."—VIRCHOW'S *Die Krankhaften Geschwülste*, Vol. ii., p. 519.

sent. That this position taken by the committee will not be unchallenged may be inferred from the editorial remarks of the *Medical Press and Circular*, which, in commenting upon the report, says: "If 'croup' and 'diphtheria' can be shown to be mutually communicable, to arise from one and the same cause, and to be attended, in many instances, with the same constitutional symptoms, then, and then only must the old distinction between these diseases fall to the ground. But with regard to this point the report of the committee is not so clear as might be desired."—*Medical Press and Circular*.

In connection with this subject, particular interest is attached to the investigations into the pathogeny of diphtheria, conducted by Drs. Edward Curtis and Thomas E. Satterthwaite, in pursuance of a resolution of the Board of Health of this city. The question proposed for solution by these investigators was the nature of the infective principle of diphtheria, and the circumstances that determine the infection. Experiments were made upon rabbits by inoculations of the diphtheritic membrane, at first upon the cornea, and afterwards into the muscular tissue of the thighs. The first method was not followed by definite results, but by the second a fatal disease was induced, which many investigators have deemed identical with diphtheria in man, but which these researches have shown to be essentially dissimilar. The results of these investigations may be summed up as follows: "I. Inoculation of diphtheritic membrane into the muscular tissue of the rabbit produces severe local lesions, and even constitutional disturbances and death. But these effects differ so in their pathology and clinical history from diphtheria in the human subject that there is no warrant for defining them as diphtheria, or for applying conclusions drawn from this inoculation disease in the rabbit to the case of diphtheria in man. II. Effects exactly similar to the foregoing and of equal severity can, moreover, be produced by inoculation of a material not only non-diphtheritic, but non-infectious to the human subject under conditions where the diphtheritic membrane is infectious; *i. e.*, when brought into contact with the mucous membrane of the mouth and throat. The material referred to is the pulpy scraping of the upper surface of the healthy human tongue. III. Effects generally similar to the foregoing, though not of equal intensity, can furthermore be produced by inoculation of a putrescent matter which is not even of immediate animal origin—namely, Cohn's fluid—allowed to spontaneously decompose (Cohn's fluid is an aqueous solution of ammoniac tartrate, potassic and calcic phosphates, and magnesian sulphate. IV. The foregoing inoculation effects are not due to simple mechanical irritation, for inoculations of sand produce no effect whatever. V. Thorough filtration of a proven virulent aqueous infusion of diphtheritic membrane or of putrid Cohn's fluid removes the infectious property of the same. Hence, in such diphtheritic infusion the poisonous quality probably inheres in some *particulate* thing, from which it is not separable by the action of cold water. VI. Thorough trituration of proven virulent diphtheritic membrane and tongue-scrapings with a high percentage of salicylic acid fails not only to remove, but even markedly to modify the intensity of the infectious quality of those substances. Hence, since salicylic acid, in even a minute percentage, is capable of permanently suspending the vital activity of bacteria, the inference is that the infectious quality of the diphtheritic membrane upon the system of the rabbit is not correlated to the vital activity of the bacteria present in such membrane. VII. If, as is not

improbable, the noxious principle in diphtheritic membrane, which produces in rabbits the effects described, be the same with or even analogous to the principle which produces diphtheria in man by direct infection, then the conclusion of VI. will apply to the infectious quality of such membrane in its relation to the reproduction of diphtheria in the human subject. If this be the case, it follows, as an important practical corollary, that *there is no theoretical ground for assuming that preventing the bacteria of a diphtheritic patch from making their way through the underlying mucous membrane will, per se, prevent general diphtheritic infection of the system.* VIII. There is no relation between inoculable virulence of a diphtheritic membrane and the period, within three days, that has elapsed between the detachment of the membrane and the inoculation of the same, nor between inoculable virulence and gross amount of bacteria present in the membrane. IX. There is a rough relation between inoculable virulence of a diphtheritic membrane and the severity of the original case of diphtheria, so far as this can be estimated by the termination of the case in death or recovery. These nine propositions are not put forth as *proven*, but merely as the results of the experiments and observations, as far as the latter go, stated in abstract form. Before the propositions can be considered proved as truths, a large number of corroborative experiments will have to be made."—*Report of Investigations into the Pathogeny of Diphtheria*, 1878.

ADENOMA OF THE UTERUS.—Prof. C. Schroeder reports two cases of adenoma diffusum uteri and two of adenoma polyposum, all of which were cured by operation. The two former were treated by scraping with the sharp curette, followed by injections of the perchloride of iron. Microscopical examination of the pieces scraped off revealed thickened uterine mucous membrane, enclosing closely packed and enlarged uterine follicles. In one of the cases of adenoma polyposum the tumor was found in the vagina; it was as large as a child's head, and was attached by a long pedicle to the body of the uterus. It was removed by the wire *écraseur*. On microscopical examination, it was found to consist of uterine glands, many of which had developed into large cysts, and of connective tissue rich in nuclei; the pedicle, which spread out like a tree in the interior of the tumor, was composed of connective tissue and smooth muscular fibres. In the other case, the microscopical structure was the same, except that none of the follicles had developed into cysts.

Prof. Schroeder states that a characteristic feature of the vegetations of the uterine mucosa—called also endometritis fungosa by Olshausen—is that the cervical canal is greatly dilated, while the os internum, on the contrary, is closed. The adenoma polyposum has as yet been but little studied, but it cannot be regarded as a pure product of the uterine mucous membrane. It is a peculiar fact that the adenoma polyposum has as yet only been met with in elderly women who never were pregnant, while the adenoma diffusum has been met with both in nullipara and in multipara.—*Allg. Med. Cent. Zeit.*, No. 47, 1878.

HAMBURG TEA.—R. Senna leaves, 8 parts; manna, 4 parts; coriander, 1 part. Mix.—*A Correspondent in "New Remedies."*

New York, January 4, 1879.

HOSPITAL PATIENTS WHO CAN PAY.

THE discussion bearing upon the contemplated experiment at St. Thomas's Hospital, London, in regard to "patients who can pay," is bringing many matters to light connected with hospital management there which have a striking correspondence with the abuses in our own systems of medical charity. There, as here, the poor are not the only ones ministered to, but fully one-third of the aggregate number of so-called pauper patients are able to maintain themselves outside, and pay a small fee for medical services besides. These belong to a class of patients who would hesitate to ask charity from any other source, and yet would not be backward in using any means for securing free attendance in hospital. The *Lancet* very truly says: "Employees in receipt of good salaries, members of the families of well-to-do tradesmen, and even those of higher station, do not scruple to abuse the charity of these institutions, and evade the payment of just fees to medical men. More particularly is this the case in regard to special maladies, when the pitiful excuse of being unable to pay for the 'best advice' is adopted to disguise meanness and dishonesty." While it is fair to suppose that this abuse of medical charity would be carried to an extreme where there are no means to check it, as for instance, in hospitals which have no provisions for pay patients, it is equally reasonable to inquire whether the establishment of such a department in the St. Thomas's Hospital will entirely remedy the difficulty. Although it may do so in a measure, it will not do so absolutely. Patients who can afford to pay good fees to outside practitioners will constantly present themselves as ordinary pay patients to such an hospital, and as long as the superintendent and managers are satisfied with the amount offered for board and lodging, no questions will, as a rule, be asked as to outside pecuniary capability of the applicants. As far as the managers are concerned, this is a pure business ar-

angement to make the institution pay as a boarding-house. The benefit of a doubt as to the ability to pay for medical services extra is always given to the patient who is ready to pay his board-bill. It is said that any misunderstanding between the managers of the hospital and the medical staff regarding this point will be satisfactorily anticipated by a scrutinizing inquiry into the worthiness of the patient's application. Without showing any want of faith in the good intentions of the managers, or any want of appreciation of the innocence of the staff, we are, nevertheless, very much interested to see how the promise can be fulfilled.

But if, contrary to the general experience in this city, we allow thus much to be possible, there is still a chance for abuse in the admission, at a nominal board fee, of good paying patients, whose cases are from a medical point of view interesting ones. The temptation on the part of the hospital staff to treat such patients, entirely irrespective of any fee, is too strong to be generally resisted. Perhaps the only exception to the rule is the ordinary college professor, who so uniformly refuses all such cases when they present themselves at his clinic, and who takes such pains to refer them back to their family physician. Whoever knew a clinical teacher to forget the claims of the profession by prescribing for well-to-do patients simply because clinical material was scarce, or merely for the reason that such cases were sometimes interesting? If the same practice would only hold good at the hospitals, it would be easy for the ordinary practitioner to protect himself against the robbery of his patients, and to prevent even interesting cases from receiving free treatment in such institutions. We are compelled to say, however, that despite the best intentions on the part of hospital managers, and a most earnest desire on the part of the medical staff to protect the interests of the general practitioner, occasionally an interesting case finds admittance, occasionally a good-paying patient is lost to some family physician, and occasionally the patient himself will make the profession feel under obligations to him for the splendid opportunity of studying his case. But every one in or out of the hospital knows that this is such an exception with patients of the paying class, that it is unworthy of serious consideration in connection with the present abuse of the pay system in hospital management here, or of the abuses of the prospective system in London.

A SANITARY INSPECTION OF OUR PUBLIC SCHOOLS.

So much has been said in these columns of the want of sanitary regulation in our public schools, that we feel almost like apologizing to our readers for referring to the subject once more. We are so firmly impressed, however, with a duty we owe to the public in general, and the school children in particular, that we cannot omit an opportunity of repeating an old story in the

hope that it may be heard at last, and that its moral will be taken to heart. The school children cannot speak for themselves, the teachers dare not, and the Board of Education, which is omnipotent in school matters in this city, says that the sanitary condition of the schools is perfect. This latter assertion would appear to settle the question, but unfortunately it does not, as the fact of frequent inspections abundantly prove.

For years the Board of Education has refused every reasonable appeal to remedy defects in ventilation, in heating, in lighting the buildings, and in caring for the water-closets outside. The only answer that has been vouchsafed to such requests has been that the schools are in good enough condition, and that no change is necessary. Several members of the Board have, by virtue of the emergency, created themselves authorities in sanitary matters, and there has been a dead-lock to any impartial investigation of the real merits of the question. When we consider that the Board is managed in the interests of a political ring, and that it is quite necessary that the ignorance, neglect of duty, and stupidity of said Board should not be brought to light, the outlook towards reform is quite unpromising. We are encouraged, however, in seeing that a new and powerful element is at work to bring about a change in the management of the affairs of the Board. *The Herald* has caused an inspection to be made of the school buildings, and has recently published a lengthy report upon the subject. No one can read this report, the authenticity and impartiality of which cannot be questioned, without being startled by the disclosures. Only a few of the schools were visited by the inspector, and these were principally primary departments. The latter are invariably upon the ground floor. The rooms are dark, ill-ventilated, crowded, exposed to drafts of cold air on one side and intolerable heat on the other; and are in close proximity to water-closets, which, by the negligence of janitors, are kept in an abominably filthy condition.

Perhaps we cannot serve our present purpose better than by making a few extracts from the report. In Grammar School No. 18 the infants in the lower seats of the gallery class are "literally roasted," while those on the upper benches "are shivering from the cold draughts pouring directly on their heads and shoulders from the lowered sashes." In another room of the same school "the heating is so defective that upon examination the temperature was found to vary from sixty-five degrees to over seventy-five degrees. No general record is taken. The children are packed as closely as possible in these rooms. As to the floor and air-space, as required by the provisions of the by-laws of the Board of Education, no attention whatever is paid, the reason given being that it is impossible under the present packing system."

Although Grammar School No. 69 is a new building, having been only opened in the latter part of 1876, we learn that "the children in the gallery classes

are in the same condition as in the other schools—are dangerously close to the radiators on the one side, and exposed to the draughts from the open windows on the other. The thermometer in this department seems to be at a discount, as no record whatever is taken of the temperature." Also the "urinals are constructed of wood, being plain wooden troughs, without lining or cover. No means have been taken to prevent the foul odors and poisonous emanations from entering the adjacent class-rooms."

In Grammar School No. 32, in the class-room on the ground floor, adjacent to the water-closets, the air was intolerable, and as a mere coincidence, of course, "several of the pupils were absent on the sick list."

The closets in Grammar School No. 33 were in the same condition as the last schools visited. "In one of the rooms the day before this visit the temperature was as low as 56°. The record of temperature in this school is not kept, as the Principal thought it useless to do so under the present circumstances."

Grammar School No. 70, in Seventy-fifth Street, like all of the preceding, is badly lighted; the staircase, which is of wood, is entirely enclosed, and is extremely dangerous in case of fire; ventilation in some rooms amounts to almost nothing, as all the fresh (?) air attainable is through the hallways, it being necessary to close the windows to keep out the foul odors of the water-closets. The playground is reported to allow not over "one square foot of ground-space for each pupil attending."

But it is useless to rehearse the results of this inspection: suffice it to say that they repeat themselves to a greater or less degree in all the schools visited. Some of the class-rooms are so dark as to compel the lighting of the gas throughout the greater portion of the day.

These facts are not by any means new to us, neither will they be to any one who has given any attention to public school hygiene in this city, but it is a matter of congratulation that they have been presented to the general public in a manner which may invite the attention of the Board and cause it to reconsider its oft-declared assertion that the sanitary condition of the schools is good. Is it not time, in any event, to demand such a change in the administration of the Board as will do away with its stupid opposition to what every one else believes to be reasonable and necessary sanitary reforms? In the Board, as at present constituted, there is no hope for any change. Is it then worth while to change the Board? This may be a question which public opinion may ask the new mayor to answer.

REPRESENTATION IN THE STATE MEDICAL SOCIETY.

A GLANCE over the Transactions for 1878, of the Medical Society of the State of New York, brings to light some interesting, not to say curious, facts.

We find first that in the State there are sixty counties, all of which, except Hamilton, have county medical societies, the total membership of which numbers 3,238. New York County has the most members (710), and Putnam the least (14). The different societies are, according to a law passed in 1855, entitled to send representatives to the State Society, the number of delegates being equal to the number of assembly districts in the several counties at the time the law was passed. All of the county societies, with the exception of Putnam, have elected delegates in accordance with this law. Comparing the number of delegates with the total county society membership, we find that the ratio is about 1 to 25. In the practical application of the law, however, notable deviations from this ratio are constantly met with, and in some counties more delegates are elected than in others which have a larger society membership, as will be seen from the following examples: Thirty-one counties whose membership varies from 15 (Rockland) to 58 (Queens), send one delegate each. Thirteen counties whose membership varies from 26 (Columbia) to 42 (Niagara), have two delegates each. Steuben, with 50 members, and Jefferson with 68, have also two delegates each.

Seven counties with memberships from 38 (Saratoga) to 118 (Monroe), have three delegates each. Oneida and Albany Counties, with respective memberships of 94 and 133, have four delegates each, and Erie County, membership 123, has five delegates. Lastly, Kings (278 members) and New York (710 members), have respectively 9 and 21 delegates.

Broome (56 members) and Queens (58 members) have but one delegate each, while fourteen counties with smaller memberships have two delegates each, and two counties, also with smaller memberships, have three delegates each. Queens and St. Lawrence have each 58 members, but the former is entitled to but one delegate, while the latter has three. The greatest contrast, however, is between Queens and Saratoga. The former with 58 members and one delegate, and the latter with 38 members and three delegates. New York County also suffers in comparison with many other counties, for if the average proportion (1 in 25) were preserved, it would have 28 instead of 21 delegates, as at present.

We commend these facts to the attention of those interested in the medical politics of the State.

TREATMENT OF IDIOCY BY TREPPANING THE SKULL.
—Dr. Fuller, of Montreal, removed with the trephine a portion of the skull of an idiot child two years of age, with a view to permit the expansion of the brain, and as a consequence, the development of the faculties. After the operation, paralysis of the arm with general coldness of the extremities set in, but disappeared after a time. The mental condition of the child has improved in a very marked degree since the operation, and, encouraged by this result, Dr. Fuller intends soon to remove another circle of bone.

Reviews and Notices of Books.

THE PRINCIPLES AND PRACTICE OF SURGERY, Being a Treatise on Surgical Diseases and Injuries. By D. HAYES AGNEW, M.D., LL.D., Prof. Surgery in Med. Dept. University of Pennsylvania. Profusely Illustrated. In two volumes. Vol. I., Svo, pp. 1,062. Philadelphia: J. B. Lippincott & Co. 1878.

A NEW work on surgery, at a time when there are so many excellent treatises upon the subject, gives rise to one of two thoughts in the mind of the reviewer. Either the author wishes to make a book merely after a particular plan, perhaps, and without originality, or he feels it his duty to present to the profession the results of his experience, and stamp the work with his individuality. How far either or both of these reasons may apply to the present case we shall see as we proceed.

To begin with, its scope is very extended. As this first volume contains over one thousand pages, and is devoted merely to the consideration of the following general subjects: "Diagnosis," "Inflammation," "Wounds," "Injuries of the Head," "Injuries of the Chest and Abdomen," "Wounds of the Extremities," "Diseases of the Abdomen," "Diseases and Injuries of the Blood-vessels," "Ligation of Arteries," "Surgical Dressings" (including bandaging), and "Injuries and Diseases of the Osseous System" (not including dislocations), we can readily infer that volume number two will not be smaller than the present, by the consideration of what remains to be executed, more especially as Dr. Agnew does not intend to omit diseases, injuries, and operations upon the eyes.

The arrangement of the general subjects is eminently systematic and practical, and embraces: 1. Name of Injury or Disease; 2. Anatomical Considerations; 3. Varieties; 4. *Ætiology*; 5. Pathology; 6. Symptoms; 7. Diagnosis; 8. Prognosis; 9. Treatment; 10. Complications and Treatment; 11. Sequelæ and Treatment. This order is the rule, to which there are some exceptions.

The author's style, though clear, is rather prolix. While we highly commend his minuteness of detail, we must certainly admit that nothing would have been lost, but much gained, by greater conciseness. Especially is this latter remark applicable to the historical details. Nor have we any great love for, nor can we see any special utility in, the introduction of so much that is statistical in such works. We allude particularly to the sixty-six pages of tables on fractures. A plain statement of the author's conclusions would have been far preferable, and would have saved much valuable space.

The introduction, "Surgical Diagnosis," is an excellent article.

Chapter I., "Inflammation," its nature, varieties, terminations, treatment, results and their treatment, opens the book proper. A more lucid exposition of the present views upon the pathology of inflammation we have not had the pleasure of reading. Our author describes its phenomena as due to: 1. "Disturbed nerve-action; 2. Disorder of the blood-vessels and their contents; 3. Passage of the contents of blood-vessels through their walls; and 4. Change in the perivascular tissues of the inflamed parts."

After the pleasure we experienced in the reading of what preceded, we were greatly disappointed to learn that our author is no milk-and-water advocate of general blood-letting or calomel as means of overcoming or limiting inflammation. The very admission of *dis-*

turbed nerve-action, which means a *diminution*, and not an *increase*, of nervous vitality, is a refutation of the soundness of the practice which employs most powerful nervous and general debilitants. The clue to the author's reason for their employment may be gained from his interpretation of the phenomena of inflammation (p. 55): "The more carefully we analyze and compare the phenomena of normal nutrition and inflammation, the more we are disposed to formulate them into a single compact statement, and conclude that inflammation is *hypernutrition*, carried on under such an extravagant plenum of supply that the germination and mutation of cell-life are generally too hurried to mature, and are therefore unstable and short-lived." *Change the italicized word to hypnutrition* and the erroneous view immediately disappears; the former says, "put a stop to so much *activity*," whilst the latter says, "tone up the *diminished* vitality."

The various forms of suppuration and ulceration are well treated, and require no special mention. Then come the different kinds of mortification, including hospital gangrene, eight pages being devoted to its history. Hemorrhage and its treatment, the treatment of wounds in all their varieties (including glanders, farcy, malignant pustule, hydrophobia, wounds of snakes, etc., and gunshot wounds) form the subject-matter for Chap. II. This division is excellent in its general and detailed descriptions, and is well and profusely illustrated. Lister's antiseptic plan is described. The "Surgical History of the War of the Rebellion" has been used to excellent advantage on the subject of gunshot wounds.

Chap. III.—"Injuries of the Head" is quite full upon fractures of the skull, concussion and compression of the brain, gunshot and arrow wounds of the head, fungus cerebri, and trephining. The various wounds of the face, salivary fistula, necrosis of the facial bones, excision of nerves in facial neuralgia, and wounds of the neck are also found in this division of the book. Wounds of the chest and contents, and abdomen and its organs, are lucidly treated in Chap. IV., as are also wounds of the bladder, anus, and rectum. The management of artificial anus from a fecal fistula is also described. Chap. V. treats of "Wounds of the Extremities," and Chap. VI. of "Diseases of the Abdomen." The article on intestinal obstructions needs a greater detail of the symptoms and diagnosis, as well as a more positive and clear indication of the line of treatment to be pursued in special cases. Strangely enough, the author makes no allusion to complete posterior or antero-posterior rectotomy for the relief of rectal stricture. Bougies and the dangerous resort to divulsion, with or without multiple nicks, are alone mentioned. We are surprised at this omission. Fifty-five pages are devoted to the consideration of herniæ. Although unnecessarily prolix, and in spite of some very bad woodcuts, the author has given us a very good and valuable article upon this subject. We are especially glad to see that he questions the justifiability of operations for "radical cure." The differential diagnosis of herniæ is very clearly made.

Under the head of "Diseases and Injuries of the Blood-vessels," the veins are thoroughly well considered and then the arteries. Aneurism is treated of in a masterly manner—its etiology, pathology, complications, diagnosis, and treatment. We are especially well pleased with the fulness and detail of its diagnosis, being arranged as a differential schema. The author should have detailed, instead of merely mentioning, Balfour's plan of treatment by rest and potas-

sium iodide. The reader would be at a loss to prescribe the proper doses of the salt, since no mention thereof is made in the text, nor is there any foot-reference where the details of the plan may be found. Otherwise the article on treatment is very satisfactory and complete, occupying eighteen and a half pages. Then follows a description of the symptomatology, diagnosis, prognosis, and treatment of special aneurisms.

We call special attention again to the excellence of the differential diagnosis described under each head; in this respect this work is in advance of many of its predecessors, and possesses a purely individual excellence.

Chap. VIII. is devoted to the "Ligation of Arteries." First, the surgical anatomy is given; then the point or points of election are pointed out; finally, the operation is described. This same plan is pursued for each artery. The illustrations in this portion of the book are simply execrable—so exceedingly bad that the author owes his readers an apology for their appearance.

Surgical dressings, including all the various kinds of bandages, are described and well illustrated in Chap. IX.

The last chapter is devoted to fractures and diseases of the bones. Eight pages are allotted to the description of the "repair of fractured bones," and a very excellent exposition it is. The rules for the general treatment of these injuries are judicious. The author's conclusions from his sixty-six pages of tables on pseudarthrosis must receive the support of all practical surgeons. The diagnosis and treatment of fractures are given at length, and no reader can find any fault on the ground that a paucity of apparatus or plans for treatment exists. The author plainly indicates his preferences, but describes all other good methods of the day, gives detailed explanations of the mode of applying the various apparatus, and does not omit certain historical data.

He prefers the weight and pulley (Buck's) apparatus for the treatment of fractures of the femur. We have no hesitation in stating our decided preference for that dressing. We are glad to note: "I do not hesitate to say that a fracture in the shaft of the thigh-bone which is cured with one-half or three-quarters of an inch shortening is a good cure, and gives no room for complaint on the part of the patient; and that the surgeon who obtains this result may walk among his professional brethren without being conscious of the least inferiority or want of skill in the management of this class of surgical injury." We protest against the indiscriminate employment of Dupuytren's apparatus in the treatment of Pott's fracture—the only treatment mentioned by our author—in the face of the fact that the plaster-of-Paris is immeasurably superior. The illustrations in this chapter are valuable in the elucidation of the text; they are profuse, but a few of them are quite bad, as figs. 574, 686, 741, 748; nor has the engraver been very happy in his delineation of figs. 757, 776, and 809, although the defect is of little moment.

The remaining articles of this work—periostitis, ostitis, caries, endostitis, osteomyelitis, sclerosis and necrosis of bone, rachitis, osteomalacia, fragilitas ossium, hypertrophy and atrophy of bones—are worked up and illustrated in a thoroughly satisfactory manner. Nineteen pages of "index" complete this volume. The strong points of the author are diagnosis and treatment. Pathology is unravelled to an extent sufficient to elucidate treatment. Each operation is described as it is alluded to (as a rule), which is an ad-

mirable arrangement for the student in particular. While we think that one smaller and less expensive volume, giving the personal observations and views of the author, would, under existing circumstances, have been preferable, we can nevertheless recommend Dr. Agnew's work on its general and individual merits.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Nov. 21, 1878.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

THE HISTORY OF SIX CASES OF ABDOMINAL PREGNANCY.

DR. T. GAILLARD THOMAS made a valuable contribution to obstetric surgery by a report of the history of six cases of abdominal pregnancy. Five cases were operated upon, and the patients recovered; the sixth case was still under observation. His experience in extra-uterine pregnancy extended to fifteen cases. Of those seven were tubal, two were interstitial, and six were abdominal pregnancy. For the physiologist and the pathologist many varieties of extra-uterine pregnancy existed, but for the general practitioner at the bedside all the varieties could be placed under three heads: 1. Tubal; 2. Interstitial; and 3. Abdominal.

By rational and physical signs those varieties could be distinguished from each other, and in certain cases the propriety of surgical interference could be based upon the conclusions reached.

The events of abdominal pregnancy were the following:

1. The fetus thus unnaturally attached might die in the early months of its life, become encysted, and in time be cast off through the rectum, through the bladder, or through the abdominal walls.

2. The pregnancy might advance to the end of the ninth month, when nature would make a persistent effort to expel the child, but, on account of absence of any way of exit, would fail. The fetus would then be retained, become encysted, and perhaps remain for years.

3. The child, shut up in its unopened shell, might act as a foreign body and give rise to suppurative action, and in that way develop hectic from absorption of septic material. All those events were illustrated by the cases related.

CASE I.—Abdominal Pregnancy—Death of Fetus early in Gestation—Discharge through the Rectum, with Recovery of Mother.

This case occurred in the practice of Dr. H. F. Walker, of New York.

CASE II.—Abdominal Pregnancy—Death of Fetus in early Gestation—Discharge through the Rectum, with Recovery of the Mother.

This case was almost an exact counterpart of the first, and occurred in the practice of Dr. Olcott, of Brooklyn.

Diagnosis of abdominal pregnancy was based upon the following data:

1. All the rational signs of normal pregnancy existed.

2. The uterus, though enlarged, was smaller than it would have been had utero-gestation existed at the time the examination was made.

3. The uterus was lifted up and pushed forward by

a soft elastic tumor, which gave none of the evidences of being a hematocele or an ovarian cyst.

4. The uterus did not present the appearance of being occupied by the products of conception when examined by the sound.

CASE III.—Abdominal Pregnancy—Laparotomy Performed at the End of the Eleventh Month of Gestation, with Recovery of the Mother.

This case occurred in the practice of Dr. Hadden, of New York.

The uterine cavity measured three and a half inches in length.

The cyst was tapped, and a fluid removed which closely resembled the fluid from an ovarian cyst. It was submitted to an eminent microscopist for examination, who reported that it contained corpuscles which he believed to be ovarian. The diagnosis of abdominal pregnancy was based upon the following data:

1. The existence of nausea and vomiting during the early months of the patient's illness. Those gave place to

2. Distinct foetal movements.

3. The presence of pigmentary deposit in the linea alba and in the areola of the breasts.

4. The presence of a large but empty uterus, without evidences of inflammation.

5. The existence of a large solid body, which rolled about freely in the cavity of the abdomen.

When the operation for the removal of the fetus was performed the placenta could not be seen; but in the light of his experience in a case of tubal pregnancy, in which he removed the placenta, and the patient's life was nearly sacrificed by hemorrhage, and the additional fact that a slight scratch of the peritoneum in the present case gave rise to troublesome hemorrhage, Dr. Thomas decided to let the placenta remain undisturbed. A drainage tube was placed in the lower extremity of the abdominal incision. The child was a female, and weighed seven pounds. The funis at one point was surrounded several times by a long hair, which cut off all circulation, and in that manner destroyed the life of the child. The patient did very well until about the fourteenth day, when she had a slight chill, that was followed by a rise of temperature to 104 F., and septicæmia seemed imminent. A clot was removed from the abdominal cavity; the cavity was washed out thoroughly and regularly by means of antiseptic injections, and the case again progressed favorably. Five weeks after the operation a small portion of the placenta was found protruding from the abdominal opening, and by careful manipulation the entire placenta was removed.

The following points in the case were regarded as specially important:

1. Had positive diagnosis not been made before the operation, and the procedure commenced as for ovariectomy, the immensely hypertrophied peritoneum would doubtless have been so wounded that the case would have terminated fatally by hemorrhage.

2. Had an effort been made to remove the placenta, disastrous consequences would probably have ensued.

3. Had the abdominal wound been allowed to close by first intention, an imprisoned and foetid placenta would have led to a fatal issue.

CASE IV.—Abdominal Pregnancy—Laparotomy at the End of Seventeen Months, with Recovery of the Mother.

In this case the fluid removed by tapping was submitted to microscopical examination, was found to

contain the ovarian corpuscle, and was believed by the examiner to be unquestionably fluid from an ovarian cyst.

A well-developed girl, weighing nine pounds, was removed at the operation. The cord was twisted upon itself in such a manner as to arrest circulation and cause the death of the fetus. The placenta was attached to the bladder and the anterior abdominal wall. It was left undisturbed, and the abdominal incision was closed in such a manner as to leave an opening for its escape. The patient rallied well from the operation, and for some time the case progressed favorably. The pulse and temperature were carefully recorded by Dr. Van Voorst, House-Surgeon at the Woman's Hospital, and from his report the following abstract was read:

Three hours after the operation the pulse was 108, and the temperature 99° F.

Twenty-four hours later the pulse was 108, and the temperature 101° F.

At the same hour on the following day the pulse was 103, and the temperature $99\frac{3}{4}^{\circ}$ F.

At 8.30 A.M. of the same day, the pulse was 120, and the temperature $102\frac{1}{2}^{\circ}$ F.

At 12 noon, the temperature was $103\frac{1}{2}^{\circ}$ F., and at 6 P.M. $102\frac{3}{4}^{\circ}$ F.

At 8.15 A.M. the following day, the temperature was 103° F. The patient was taken with vomiting.

At 12 M., the following day, the temperature was $103\frac{3}{4}^{\circ}$ F., and at 3 P.M. the same.

At 3.30 P.M., the abdominal cavity having been washed out with a solution of carbolic acid, the temperature was $100\frac{1}{2}^{\circ}$ F.

At 7 P.M. of the same day the temperature was 103° F., and at 8 P.M. the cavity was again washed out.

At 10 P.M. the temperature was $102\frac{2}{3}^{\circ}$ F. The carbolic injection was repeated.

At 11.15 P.M. the temperature was $101\frac{1}{2}^{\circ}$ F.

The case thus progressed, the temperature rising to 102 and 103 or more, and almost invariably falling after each antiseptic injection.

From time to time portions of the placenta were discharged as the cavity was washed out, and finally the patient was permitted to return to her home, with a small, hard portion of the placenta still remaining attached to the abdominal wall. She was able to continue the injections herself. The placenta was finally entirely discharged, and a complete recovery made. The case illustrated the great value of antiseptic injections.

CASE V.—Abdominal Pregnancy of Twenty-two Months' Standing—Fetus delivered by Laparotomy, with Recovery of the Mother.

The case occurred in the practice of Dr. Coates, of Connecticut, and had been published in full in the volume of Transactions of the Connecticut State Medical Society. The operation was performed at the Woman's Hospital. The tissues were severely lacerated by forcible removal of many of the bones.

Special attention was directed to the point that hereafter, in a similar case, instead of tearing the bones out, he would remove those only which could be easily taken away; then, leaving the abdominal wound open, he would keep up antiseptic injections, and await their spontaneous discharge.

CASE VI.—Abdominal Pregnancy now advanced four Months, and under Observation.

The patient was a woman thirty years of age, and under the immediate care of Dr. Franklin, of New York.

The diagnosis of abdominal pregnancy was based upon the following conditions:

1. The existence of all the ordinary signs of pregnancy.

2. The existence of a painful tumor behind the uterus.

3. The expulsion of deciduous membrane without abortion.

4. Displacement of the uterus by a tumor, which gave none of the evidences of hematocele, ovarian cyst, or fibroid tumor.

In watching the case Dr. Thomas was governed by the principles, that although he had successfully operated in the cases related, he had not resorted to operative interference without good reason to believe that delay would be dangerous. Operative procedure should be delayed until nature pointed to the channel of extrusion which she selected.

In the case under observation the tumor seemed to be burrowing downward, and that tendency might make it possible to remove the fetus through the vagina in the event that surgical interference became necessary.

Commenting upon the cases, Dr. Thomas remarked that, if they were reported simply as six cases of abdominal pregnancy, they would lead to erroneous conclusions, for surely it might be inferred from the results that extra-uterine pregnancy had been bereft of its old-time dangers. But the cases were not so reported.

Of the remaining *nine* cases of extra-uterine pregnancies, two were interstitial. Of these one died, and one recovered only after passing through a most dangerous surgical interference. The remaining seven were cases of tubal pregnancy. Of those six died, and one survived only after submitting to a capital operation, which of itself might have destroyed the patient's life.

With reference to the time for surgical interference in cases of abdominal pregnancy, it was often wise to allow the process to continue until the time of full development of the child and await the efforts of nature.

But suppose it was pretty certain that the woman was carrying a dead child, was it wise to resort at once to surgical interference? In answering the question the following facts were to be taken into consideration: one danger attending operative interference was hemorrhage. The longer the placenta was allowed to remain, the more certain was it to undergo such changes as rendered hemorrhage less liable to occur when operative interference became necessary. Another danger was septicemia. The more thoroughly the foetal envelopments became atrophied, the less the danger from that complication.

No fixed rule applicable to all cases could be given. The following were given as general rules to guide us in the management of cases of abdominal pregnancy:

1. Before full term, if the child was alive, its growth might be carefully watched with the hope of being able, at the end of the ninth month, to deliver by the operation of laparotomy a living child, and also of saving the life of the mother.

2. Should the child die early in abdominal pregnancy, delay was advisable, but it should not be carried to the development of hectic and septicemia.

3. At full term it was doubtless the best rule to await the evidence of constitutional disturbance, and then to meet its development promptly by operative interference.

The paper being before the Academy for discussion,

Dr. W. T. Lusk remarked that the success obtained in the cases reported was most astonishing. It would seem from all statistics which had been furnished that to wait was the proper course to pursue, but Dr. Thomas had resorted to surgical interference when it seemed necessary, and all must agree that, from the results obtained, a serious revision of our views upon the subject must be made.

Dr. Lusk referred to the fact noted by Dr. Thomas, and also by Spiegelberg at about the same time, namely, that the sac became attached to the abdominal walls so that when the incision was made it entered the sac directly.

It did not always happen, however, that such attachment took place, so that the opening was directly into the sac, and reference was made to a case illustrating that point. The patient finally recovered from the operation, but only after a long period of suppuration and an attack of septicæmia. She died soon after of phthisis.

With reference to cases in which the child was living at the time the operation was performed, there had been reported eight cases in which living children had been delivered, and the lives of four of the mothers were also saved.

Dr. Lusk also thought there was no question but that one of Dr. Thomas's cases would have terminated fatally had it not been for the most efficient after-treatment and the benefits which the patient derived from his large experience in ovariectomy.

Dr. FORDYCE BARKER remarked that one of the most important points alluded to by the author of the paper was the results of the surgical operation. They were such as rendered all rules with regard to these cases more or less doubtful at the present time. There were two points in the method of procedure which were to overturn the value of preceding statistics with reference to operative interference in cases of abdominal pregnancy.

One was, leaving the placenta *in situ* after the operation. It was generally accepted at the present time, by the most advanced men, that the safety of the patient depended greatly upon the fact of leaving the placenta undisturbed.

The second point was the great value of the subsequent antiseptic treatment.

Those two points were sufficient of themselves to change entirely the future results of this operation, consequently we might say that past statistics were at the present time really of but little value as a guide to the management of this class of cases.

To the conclusions reached by Dr. Thomas, Dr. Barker gave his hearty concurrence. To be sure, many cases were seen which terminated satisfactorily by the efforts of nature; but that fact did not in the least invalidate the value of surgical interference.

The advancement which had been made in surgery and in the after-treatment of important operations was such as enabled us to obtain results which would not even have been dreamed of years ago. To the cases referred to by Dr. Lusk, Dr. Barker added four, already reported, in which the life of the mother was saved by surgical interference.

Reference was then made to two cases of abdominal pregnancy occurring in his own practice, which were cured by nature, the fœtus being discharged through an opening in the abdominal walls in the left iliac region.

A third case was referred to, which had been diagnosed by several eminent surgeons of the city as cancer of the rectum. It proved to be a case of abdominal pregnancy, with an opening into the rectum

through which the fetal bones were discharged. A recto-vaginal fistula was also formed in the same case.

Further reference was made to a case, reported several years ago at the Medical Society of the State of New York, by Dr. Parkhurst, of Herkimer, in which the fetus was carried fifty years, and then removed at post-mortem examination.

In conclusion, Dr. Barker expressed his firm belief that the success which would be obtained hereafter by adherence to two principles, namely, leaving the placenta undisturbed and adopting a judicious antiseptic treatment, would entirely revolutionize the statistics which had been published upon the question of operation in cases of abdominal pregnancy.

Reference was made by Dr. Sell and Dr. Mundé to a case which occurred in the service of Dr. Brown, in one of the Vienna hospitals.

The Academy then adjourned.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, December 2, 1878.

DR. J. C. SHAW, PRESIDENT, IN THE CHAIR.

CERVICAL PACHYMEINGITIS.

DR. V. P. GIBNEY read a brief paper, in which he reported two cases of cervical pachymeningitis. The following is an abstract of the histories:

CASE 1.—*Pachymeningitis Cervicalis Hypertrophica occurring in a Lad—Cervical Paraplegia, with General Paralysis almost Complete—Case still under Observation and Progressing Favorably.*

THE patient, a boy at 10½ years, was admitted to the Hospital for the Ruptured and Crippled, August 22, 1878. His family history was exceptionally good. He had been considered a delicate child until he was eighteen months old. From that time until one year prior to his admission to the hospital he had enjoyed fair health and was free from any paralysis or deformity. In August, 1877, he was pushed against a pile of lumber, striking his back in the lower spinal region. It was not a severe injury; he complained very little, and his mother was unable to find any bruise. The immediate effect passed off within twenty-four hours, and nothing was complained of or observed until the January following, when he had a paroxysm of shooting pains in the back. For a period of two weeks the paroxysms were frequent, and were most severe at night. Relief then came, and he seemed perfectly well until the beginning of June, 1878. Without known provocation, he then began to bend his neck forward in walking and complained of pain post-cervical. In the month of July considerable pain and tenderness, associated with a peculiarity in his walk were observed, and there was also a moderate degree of scoliosis. There was also a cervico-dorsal prominence, though slight and uniform. There was no angular deformity. When admitted to the hospital in August the following symptoms were recorded: a stooped position, the head deflected forward more than twenty degrees from the vertical bearing, a moderate dorsal scoliosis and an unusual degree of care in walking or sitting. There was no angular prominence at any portion of the spinal column, no tenderness on pressure over the spinous processes—though that had been a prominent sign—and no tenderness on concussion.

On percussion over the posterior wall of the pharynx the patient complained of pain, yet no tumefac-

tions or bony irregularity could be discovered in that region. Motion in the upper cervical region was normal, but was limited in the lower cervical and the upper dorsal.

No reliable signs of a spondylitis or of a spondylarthrocaia could be detected. The thorax presented some rachitic changes anteriorly. A head-support was applied, and with that the deformity was nearly overcome. Cod-liver oil and a tonic were prescribed.

During the following month he did very well. In the month of October the head showed a great disposition to fall forward; the head-support became irksome; the patient slept poorly considerable of the time, and the pain and tenderness in the cervico-dorsal region increased. He took to his bed; his chin, in the lateral decubitus, rested upon the sternum. He could not be induced to change his position, and, if left undisturbed, made no complaint. He had vomiting, and the tongue was heavily coated. Ergot, iodide of potassium, and vesication, were the special medicinal measures employed. On the first of November there was a decided improvement; but on the fourth he was again worse, and on the 11th there was loss of power absolute in the arms, and partial in the forearm and hands, and there was almost entire loss of power in the lower extremities. The reflexes were exaggerated. Anesthesia on posterior surface of thighs well marked. Pulse, 120; respiration, 20; temperature, 99½ F.

Nov. 14th. Exaggeration of reflex abnormality of sensibility remained. The limbs frequently jerked on the slightest provocation, and assistance was required to restore them to the desired position. Urine drawn by catheter. Pulse, 112; respiration, 26; temperature, 100¼ F. No appreciable atrophy had occurred. All the muscles acted well to medium Faradic current. The electro-sensibility was perceptibly diminished.

Nov. 17th. Has moved the right arm since yesterday. As the forearms were in pronation the hands exhibited a typical approximation to the *main-en-griffe* of Charcot and Joffroy.

Nov. 20th. Urine had specific gravity of 1012, faintly acid, and contained flaky deposits and phosphates. Temperature, 100¼ F., the highest yet reached.

Nov. 21st. Decubitus dorsal, with lower extremities extended, a position he had not been able to assume since his confinement to bed. Was able to raise both arms from his side to a right angle and to extend the forearm completely.

Nov. 25th. Epileptiform tremors in legs were marked. He could flex the left thigh with considerable force.

Nov. 28th. Was able to sit up all day, and to use his left arm in feeding himself.

Nov. 29th. Incontinence of urine and of feces. Electrical responses as good as they were one week ago.

Dec. 2d. No incontinence of either urine or feces during last two days. Pupils for the first time dilated. Fundus of the eye normal. Sensation in the thighs returning. Ergot and iodide of potassium had entered largely into the treatment. Commenting upon the case, Dr. Gibney thought we were left to accept one of these conditions in making a diagnosis:

1. Was it a spondylitis? The absence of any exostotic growths either on the bodies of the vertebrae anteriorly or on the processes, the history of the disease, and the kind of paralysis, in his opinion, excluded spondylitis.

2. Was it spondylarthrocaia, or Pott's disease of the spine? The history of a fall without evidence of

external violence would suggest very forcibly vertebral disease. Still, within twenty-four hours all tenderness and immediate effects of the fall had subsided, and he was perfectly well and free from deformity for *three months*. The fall was charitably considered as an improbable factor in the etiology of the disease present. It was to be remembered that the first real signs of the disease began in January, 1878, when colds were very prevalent, and, in the absence of any known exciting cause, it was assumed on circumstantial evidence that he contracted a cold, and that the effects of the cold were confined to the cervical spine. The shooting pains about the head and neck were paroxysmal and severe; they lasted about two weeks, and the patient was relieved. Then for five months he seemed perfectly well. Vertebral caries did not act in that manner.

Again, when the torticollis appeared, the deflection of the head was forward, and not backward, as was the rule in torticollis from vertebral disease. Since he had been under the doctor's observation, over three months, tenderness on pressure over the spinous processes had been nearly continuous. As a *rule*, to which there were but few exceptions, that sign was not present in spinal caries. Furthermore, extension and support of the head were intolerable. On those grounds Pott's disease was excluded.

3. Was it a case of pachymeningitis cervicalis hypertrophica? From the symptomatology as described by Charcot and Joffroy, from the exclusion of the two diseases mentioned, and from the kind of paralysis—that which belonged to spinal compression, Dr. Gibney arrived at that diagnosis. The case as yet was not complicated with any notable cord-lesions. There was no surety, however, that such lesions would not follow sooner or later, but it was hoped that the iodide of potassium would save the patient from their development.

CASE II.—*Pachymeningitis Cervicalis Hemorrhagica—Partial Recovery.*

The patient was a girl *æt.* 17 years, and of German parentage. Family history unreliable. The history of the case was that, in September, 1874, she went to bed in good health, slept well, but about half an hour after rising on the following morning, and while at work, she felt a sharp, sudden pain all over the "front walls of her chest," and moderate pain in her back. The pain passed off in about a minute. She had no vomiting, and probably no fever. Shortly after she tried to sew, but found it impossible. At about that time she experienced a numbish sensation in the arms and the forearms, and creeping down the body and lower extremities. She attempted to drink her coffee, but the cup fell from her hands. She tried to walk, but failed in the attempt. By noon she had complete paralysis of all four limbs, and suffered from severe pains in her thighs. She was carried to the German Hospital, and had to be fed for three months, during which time she was unable to sit up or to walk. Her urine was drawn with catheter, and the bowels moved involuntarily. She had bed-sores. She remained in the hospital thirteen months, and within that time there was considerable improvement, so that she could use her extremities, and the incontinence ceased. August 20, 1877, when she came under Dr. Gibney's observation, he found no evidence of disease in the thorax, the teeth were in good condition, the tongue and uvula normal, hearing good, and fundus of the eye normal, and no trouble with the urinary organs. Menstruated twice when sixteen years old, but never since. General health

good. No spinal tenderness or kyphosis or skoli-osis. There was neither paralysis nor atrophy of the lower extremities. The right arm was normal, but the forearm was somewhat smaller than the left. There was complete atrophy of the thenar and the hypothenar eminences, and the hand and the wrist presented the classical *main-en-griffe*. A detailed account was then given of the reactions obtained by the use of the Faradic and the galvanic currents.

Dr. Gibney believed that the suddenness of the onset of the attack and the result were so characteristic of meningeal lesions as to leave no room for difficulty in diagnosis. As to the cause of the hemorrhage, he had no means of knowing, and in a girl of that age it was a matter of speculation.

The paper being open for discussion,

Dr. E. C. SEGUIN remarked that the cases reported, he thought Dr. Gibney would admit, were characterized by a certain degree of acuteness in their development, which was rather against the course of chronic pachymeningitis cervicalis.

He thought that the first case was open to a fourth supposition in diagnosis, and that was common meningo-myelitis. The development of that disease was frequently subacute, and there was a combination of symptoms, such as irritative neuralgic pains in the spine, and perhaps in other parts of the body, and sometimes involvement of the spinal cord.

With reference to the second case, there could be an expression of stronger doubt as to its being one of pachymeningitis, even of the hemorrhagic variety, for the dura mater was a tissue which was not liable to hemorrhagic infarctions. With but few exceptions pachymeningitis hemorrhagica, whether cerebral or cervical, was in the first place pachymeningitis which gave rise to certain symptoms, and was followed by a clot in the newly-formed tissue.

Another objection was the well-defined paroxysmal symptoms without the occurrence of spasmodic symptoms so frequently accompanying the escape of blood between the arachnoid and the dura mater. If there was an escape of blood into the healthy dura, it was difficult to say why it should be localized, and not extend up and down. As to the pathological condition which might give rise to the symptoms of the second case, Dr. Seguin suggested hemorrhage into the gray matter of the cord. Another possible explanation would be acute red softening of the spinal cord. That was an exceedingly rare lesion, but he had seen one case, and in that instance the diagnosis of hemorrhage into the spinal cord had been made.

His main reluctance to accepting the diagnosis given by Dr. Gibney was the acute and subacute course of the two cases.

Dr. GIBNEY remarked that he excluded meningo-myelitis because there was no elevation of temperature whatever. As to the suddenness of the invasion, it was to be remembered that in the first case the patient suffered from an attack some eight or nine months prior to the appearance of the paralysis, which lasted for only two or three weeks, and then there was an apparent recovery. Following that were other attacks, which were accompanied by pains for three or four months, which agreed well with the painful stage of the disease as described by Charcot and Joffroy.

With reference to the second case, the diagnosis was based upon the tremors present three or four years subsequent to the sudden attack, the contractures, the position of the hand, and the method of invasion. He thought there was hemorrhage into the dura mater, and that it probably involved the cord itself.

Dr. SEGUIN remarked that the symptom *main-en-griffe* did not necessarily indicate the existence of pachymeningitis cervicalis. It was simply an expression of paralysis of muscles supplied by certain nerves, without reference to the situation of the lesion.

TREATMENT OF CHRONIC TRIGEMINAL NEURALGIA.

Dr. E. C. SEGUIN reported three cases of chronic trigeminal neuralgia which were cured by medicinal treatment (see p. 6).

The paper being before the Society for discussion, Dr. GREY inquired whether any member had tried the galvanic current in the treatment of trigeminal neuralgia. He referred to a case reported by Niemeyer, in which cure was effected by the use of the galvanic current after all other known means had failed; and also to a case under his own care, in which violent neuralgia of the thigh was relieved by the same means and under like circumstances.

Dr. KINNICUTT remarked that he had employed the galvanic current in the treatment of acute cases of trigeminal neuralgia, and that relief had been afforded, but it was only temporary.

Dr. SEGUIN remarked that the galvanic current was a measure which should be used more than it was, but there were practical difficulties which to a very great extent rendered it unavailable. It was rare that the physician could spare the necessary time, or the patient meet the necessary expense, attending that method of treatment.

Dr. SPITZKA remarked that heretofore, in cases of trigeminal neuralgia, when he had not been able to discover indications for treatment arising from reflex causes, or central disease, or constitutional phases, he had told his patients that he could do nothing for them whatever; but, from the results obtained in the cases reported, he should be encouraged to adopt the plan recommended by Dr. Seguin. He then asked the following questions:

1. What were the indications for the use of aconitia in the treatment of cases of trigeminal neuralgia?
2. Why was the term epileptiform used in connection with one of the cases reported?
3. Should not the diplopia, the unequal pupils, the loss of memory in one case, be regarded as symptoms pointing to some general central disease?

With reference to his own experience in the use of aconitia in other painful affections, pushing the remedy until its physiological effects were produced had seemed to be a rather dangerous procedure in some patients.

In one case he had pushed the remedy so that it simply produced a slight tingling, and had not strong measures been resorted to the case would have terminated fatally.

Dr. SEGUIN in reply stated:

1. That he knew of no special condition which indicated the use of the aconitia.
2. He used the term epileptiform because it best described the suddenness with which the attacks came on.
3. He did not believe the patient referred to had any central disease, for he had tested him in every direction with the view to such discovery, and had found nothing.

With reference to impairment of memory, it could reasonably be expected that the memory of a man, who for ten years had suffered untold agony, might be affected.

The contracted pupil was upon the same side with the pain, and was due probably to simple irritation of the trigeminus.

The diplopia was present only while the patient was taking medicine.

Dr. KINNICUTT remarked that he was induced to use ergot in the treatment of one case of trigeminal neuralgia of eight years' standing, because the nitrite of amyl always produced bad effects. The result obtained by the use of the ergot, given in doses of one drachm and a half of the aqueous extract in the course of twenty-four hours, had been favorable.

Dr. G. M. BEARD remarked that the conclusions arrived at by the author of the paper harmonized with his own convictions regarding the use of powerful remedies and pushing them until marked physiological effects were produced. The idea was old, it was true, and there had also been a reaction against it which had been carried too far. The principle was illustrated in the treatment of syphilis and other diseases in which the best results were obtained by producing the physiological effects of powerful drugs.

With regard to the use of electricity in the treatment of the disease under consideration, judging from his own experience, the prognosis certainly was very bad, while in the treatment of ordinary trigeminal neuralgia the prognosis was very good. He had no recollection of ever having cured a case of epileptiform neuralgia by the use of electricity. He had not been able to confirm the German case referred to, and regarded the result obtained there as an exception, the like of which might not be seen in a thousand years to come. Such was not the fact, however, with reference to ordinary trigeminal neuralgia.

Dr. Beard thought all would agree that neuralgia was only a symptom, and that when twenty cases were treated, we might in reality be treating twenty different diseases. Therefore it was not safe to generalize with reference to the action of any special remedy.

With reference to the use of gelsemium, his custom was to begin with doses of from three to five drops, and gradually increase. If no idiosyncrasy was discovered, he ceased to fear the ill effects of the remedy, and did not hesitate to push its administration to full doses.

Dr. SEGUIN wished to record his favorable experience in the use of phosphorus in the treatment of ordinary trigeminal neuralgia. He had obtained more satisfactory results from its use than from the use of gelsemium.

Dr. GREY remarked that he had been made aware of the danger of pushing powerful remedies until they produced their full physiological effects, and referred to cases of chorea in which he had seen dangerous symptoms produced by the use of arsenic.

Dr. SILAW shared in the opinion that pushing remedies until they produced full physiological effects was the true method for obtaining the most satisfactory results in the treatment of many diseases.

Dr. McBRIDE directed attention to the importance of determining that no cardiac disease was present in cases which were to be treated by the use of aconitia.

The Society then adjourned.

IRON WHICH WILL NOT RUST.—Prof. Barff has discovered that if iron be subjected to the action of steam having a temperature of 1500° F., it is covered by an incorrodible coating of the magnetic oxide, giving the finished article a dull-black appearance, susceptible of a slight polish. Salt or fresh water, vegetable acids, and all other ordinary oxidizing agents have no effect on the iron prepared by Barff's process. It should be called "BARFF'S iron," after the inventor.

New Instruments.

A CONVENIENT INHALER.

Dr. J. O. ROE, of Rochester, N. Y., has devised a convenient and inexpensive inhaler, which promises to give very general satisfaction.

The apparatus is made of Japanned tin, and, as will be readily seen, consists of a lower portion or receptacle for the hot water and medicated solution, and an upper portion or cover. The lower portion is simply a large cup holding about a quart, with a head or mark to indicate the proper amount of fluid to be used. The cover is essentially an inverted cup fitting inside of the lower and extending about two-thirds to the bottom, with a flange around the base which fits the edge of the other. The portion of the cover above the upper border of the cup tapers sufficiently to admit the attachment of a flexible tube, which may be of any required length, with a simple mouth-piece at the extremity for inhaling. The double-valve mouth-piece and the thermometer of Mackenzie are dispensed with, as they are ordinarily quite unnecessary and render the inhaler more complicated and costly. In the flange of the cover, and also near the edge of the rim, numerous small holes are punctured for the passage of air.

ROE'S INHALER.

The inhaler is used as follows: The cover (A) is removed and the cup filled with hot water (from 160° F. to nearly the boiling point, as required) up to the head or mark (C) on the side of the cup; the medicine or medicated solution to be inhaled is then put in, and the cover replaced, when the inhaler is ready for use. On inhaling, the air is drawn or exhausted from the cavity or air chamber in the upper portion of the cover above the fluid rushing in again through the openings in the flange at (D) and drawn through the corresponding openings in the rim at (E) and up through the solution, as shown by the direction of the arrows, breaking up into fine bubbles on the surface and passing on to be inhaled, carrying the medicated steam with it. The apparatus is manufactured by Geo. Tiemann & Co., N. Y.

A NEW SUBCUTANEOUS SAW, KNIFE, AND BONE RASP.

By GEORGE F. SHRADY, M.D.

A SHORT time ago, having occasion to operate upon a case of ununited fracture of the tibia and fibula, I felt the want of a subcutaneous saw and rasp which would bare and roughen the ends of the fragments at the same time there would be no danger of injuring the soft parts. I accordingly devised this instrument, which was made for me by Mr. Stohlmann, of the firm of Geo. Tiemann & Co. It could not, however, be finished in time for use in the case for which it was designed; in fact, it is just now completed. This statement is perhaps necessary to explain why I have not, as yet, made a trial of it in a similar case or in any other of the many operations which may come within the range of its adaptability. I believe, however, that there can be no doubt of its perfect working and of its extended usefulness, and accordingly offer it to the profession.

As will be seen by the cuts, the instrument consists of a trocar, fenestrated canula (Fig. 1), and a

staff (Fig. 2), with handle and blunt extremity. A portion of this staff at a short distance from the extremity is flattened, one edge (B) being made into a knife-blade, and the other edge (C) being provided with saw-teeth. This staff (Fig. 2) is intended to replace the trocar in the canula after the latter is introduced. When in position (Fig. 3) either the saw (C) or the knife (B) edge of the shaft, according to the way the latter is turned, corresponds with the opening in the canula. The saw or knife can then be worked to and fro within the canula by a piston-like movement, the canula being steadied by grasping the flange (D) at its base. If it be necessary to work the instrument as an ordinary blunt-pointed sheathed saw or knife, the shaft can be fixed in the canula and made into one piece by a thumb-screw in the handle. The portion of the canula at the back of the opening is made extra

strong and is of the same thickness as the blade, so that in sawing there is no stoppage to the passage of the instrument through any thickness of bone. At the risk of prematurely bespeaking its usefulness, I am willing to believe that the instrument can be employed in any operation where it is necessary to use a saw, rasp, or knife upon any bone, or other tissue, under the skin, and through a small opening. In ununited fracture the ends of the bones may be perforated with the trocar, may be roughened by the saw or rasped by the knife. Subcutaneous osteotomy may be performed by it, as for instance, Adams' operation for ankylosis of the hip, Ogston's operation for genu-valgum, Marsh's operation for "bow-legs," the various excisions, and also operations upon the jaws, upper and lower,—in fact upon any bone the surface or edge of which can be reached by a trocar. The soft parts are protected from injury, no matter which way the instrument may be worked. The saw-blade is blunt at its extremity, and is guarded on all sides except on its limited cutting surface. The same may be said of the knife. The working of the saw to and fro in the canula is sufficient in sweep to insure the division of any bone having a diameter less than the length of the cutting edge. Still, as this process is much slower than when the saw is used in the ordinary way, it is perhaps better to restrict its employment to operations on the smaller bones, to cramped localities, and to situations where there is special danger of wounding some neighboring vessels. All that is necessary in using this saw is to thrust the trocar and canula into the limb, the fenestra of the canula being alongside of the bone upon which the operation is to be performed. The trocar is then withdrawn, the staff introduced in its place (Fig. 3) and worked as already described. The instrument is made of different sizes, to suit the different purposes for which it may be employed.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 22 to December 28, 1878.

TILTON, H. R., Major and Surgeon. Par. 5, S. O. 245, A. G. O., Nov. 12, 1878, granting him an extension of his leave of absence for two months, is amended to grant said extension on surgeon's certificate of disability. S. O. 274, A. G. O., Dec. 21, 1878.

KINSMAN, J. H., Capt. and Asst. Surgeon. Leave of absence extended one month. S. O. 104, Div. of the Atlantic, Dec. 23, 1878.

Medical Items and News.

VACCINATION IN THE PUBLIC SCHOOLS.—Since the commencement of the present school year, eight thousand eight hundred and twenty-seven vaccinations have been made by the Health Board upon the children of the public schools.

YELLOW-FEVER FUND.—Among the earliest subscriptions to this fund was the handsome sum of one hundred dollars from Messrs. Wm. Wood & Co., medical book publishers of this city. Dr. Thomas L. Neal, of Dayton, Ohio, writes: "There is a small fund unexpended here from the Yellow-Fever Relief Committee, which the Treasurer informs me can be allowed to go to the relief of the widows and orphans of deceased physicians. Dr. Minor, of Cincinnati, promises to try and secure any remaining fund there may be at that place."

Original Lectures.

AVOIDANCE OF PAIN IN THE DRESSING OF SURGICAL CASES. HYPERDISTENTION OF ABSCESSSES.

BEING REMARKS BY

GEO. W. CALLENDER, F.R.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, LONDON.

Delivered at the Bellevue Hospital Medical College, N. Y., Jan. 4, 1879.

(Phonographically reported for THE MEDICAL RECORD.)

(Mr. Callender, having been invited by Dr. Lewis A. Sayre to occupy his lecture hour, and having been appropriately introduced, spoke as follows:)

GENTLEMEN:—I cannot but be pleased by the too flattering manner in which you have received me. I came here to mark, to listen, and to learn; but perhaps, as I am now present with you, and as the old saying has it, "the looker-on often sees most of the sport," I may perhaps venture to offer some remarks upon two or three points which have attracted my attention during the brief time I have been among you.

And first, in reference to your hospitals. Those that I have seen have all been well and efficiently managed, and their general excellence seems to me beyond all praise. I have noticed with satisfaction the great care exhibited on all sides for the welfare of the patient. I cannot express myself too strongly respecting your clinical teaching, which, so far as my experience goes—and you must know that I have visited all the great centres of medical learning in Europe—is unsurpassed anywhere. And then there is another point which interests me, and it is this: that, as I hope I may safely say it is in my own country, so I am sure it is in this, that the well-being of the patient is the first consideration. The interest shown in this direction by the united and harmonious efforts of the visiting staff, the house staff, and the nurses, stand out as a great and shining light. I am glad to find the surgeons here are not cramped by any preconceived view or prejudiced by any treatment, but are willing to try any plan or method, and to be influenced entirely by the results obtained under their own observations.

If I may be permitted to detain you a few moments, I think I may say modern surgeons have quite come to this point respecting all of their cases—I allude more particularly to surgical cases and operations—that patients may be expected to convalesce as a matter of certainty; and, as far as life is concerned, the results are invariably good. But there is another point which, apart from saving life, more particularly interests me, and to which I have been giving attention of late, and that is, patients should convalesce with certainty; but not only this, but so convalesce without an ache or a pain. I think I may venture to say that even so serious a case as the amputation of any one of the members may be conducted, from first to last, without causing the patient any pain. You may think I dwell too much upon details, but it is, and I have always held that it is, on the careful attention to such minutiae that the success and perfection of our treatment depends. May I be allowed to offer two or three illustrations as an explanation? You all know that certain little patients come under our notice who are suffering from what is commonly called harelip. When we operate upon such patients in my

country—and I presume it is pretty much the same in yours—we relieve the patient of much suffering by placing him under an anæsthetic. For such little children we use chloroform; for such grown up children as ourselves, we use ether. Besides the irritation produced by the wound, it is common to draw the margins of the wound together, and support them by strips of adhesive plaster drawn across the face. This procedure becomes a source of discomfort to the child, who cries and complains, as would be expected. But now, gentlemen, to avoid this, and to save that little one from a considerable amount of pain, it is my constant practice—and I trust you will not think me egotistical in frequently referring to my personal experience—to apply such strips to the face of the child for some three or four days prior to the operation. The child thus becomes accustomed to the restraint, and when it comes out from under the influence of the anæsthetic, it suffers, from the reason of its being so accustomed to this restraint, less than would otherwise be inevitable.

Now, I dare say that few of you think, unless your attention has been directed to the subject, of the great discomfort that is caused by the removal of adhesive plaster from a surface upon which hair may happen to grow. Perhaps some of you may have chanced to have had plaster applied to some such parts of your person, and if so, your experience is far less pleasant upon its subsequent removal. I would recommend you to so apply plaster as to never necessitate its removal until the treatment is complete. Now, take a breast amputation, and let us suppose that we secure the dressing by means of straps of plaster. Plaster so used should never be removed until the treatment is complete. When the dressing has to be changed, you are to cut out the space over the dressing, at the point where it leaves the wound and passes on to the skin. Renew your dressing, and rejoin the divided plaster by means of a strip laid over that first applied. And this may be done again and again every successive dressing, leaving the first applied plaster still adherent to the surfaces of the integument. Although this seems like a small matter, yet I assure you that these small matters materially add to the comfort of the patient, and to your success as a practitioner.

Another small matter. We are often called upon to deal with large wounds resulting from the removal of mammary tumors. It is a common practice to retain the arm across the anterior portion of the chest by means of a bandage lightly passed around the neck. Now, when the time comes for dressing the wound, some twenty-four or forty-eight hours after the operation, the bandage is loosened and the forearm and the arm are removed to the side of the body. And what takes place? The muscles have been restrained for some time; when this is done they resent the movements; you will feel them quivering under your hand. First, the biceps, and then the pectoral muscles quiver under the movement; and the patient with a great start cries out with pain. Now, why is this? Why, irritated by the action of the biceps, the pectorals, from their insertion to their attachment, are started into action; the whole wound is disturbed. The adhesions are probably rent asunder, and it is no wonder that the patient under these circumstances complains of pain. Now, let me tell you, gentlemen, how all this may be avoided, and in the simplest possible manner; and perhaps Professor Sayre will permit me to use him as a model on which to demonstrate its simplicity. If I want to prepare for the dressing of the wound, I grasp the arm firmly so as to control entirely the biceps. I now take hold of the forearm

and move the arm to the extreme of extension, and as I do this I feel the biceps quivering under my grasp; but it is unable to act, and no irritation follows in the pectorals. While grasping the biceps the arm is moved slightly to the side and is now so circumstanced that the dressing may be easily removed. I can from a practical point of view tell you that, by taking this precaution, the dressing may be effected without occasioning the patient the slightest pain. Now let me commend this to you.

Then again, with reference to amputations, not only must the patient be gotten well, but during his convalescence he should be kept free from pain. In the case of an amputation of the lower extremity I place the limb upon a splint and see that it is carefully adjusted and swung; the splint is provided with an arrangement that will allow of dressing the stump without in any way disturbing the parts. I hope I may have an opportunity of showing this instrument to you upon some future occasion. You are all probably acquainted with the manner in which the barrels of our ordinary breech-loading fowling-pieces are dropped, so as to receive the cartridges. In a similar manner a catch placed under a portion of the splint allows of sufficient of that splint being dropped from beneath the stump to permit of the removal of the dressings and of their replacement without the slightest disturbance of the parts, and without giving rise to the slightest pain. I can assure you that in this way you can dress and redress an amputation stump without the patient's even knowing the applications are being changed. And to show you how carefully these operations have to be conducted, I may add that, if during the change of the dressings, the slightest jar of the apparatus is permitted, the patient will at once recognize the error in treatment by starting of the limb and by complaints of pain.

Now, there are many ways in which pain and discomfort may be induced. I will mention one condition. There are, what I have ventured to write upon, emotional irritations. I mentioned a case of this kind only yesterday, in visiting one of your hospitals, that of a child who had been cut for stone. I will give you another instance in point: A man lay in Kenton Ward, a ward which had come to me by descent, through Sir James Paget and Mr. Stanley. The man had sustained a severe injury of his forearm. The muscles, and tendons, and nerves, indeed all there was to divide, save the bone, had been cut through in a machinery accident. We stitched all these structures together, and I suppose you do the same here; and we are hoping the day is not far distant when not only tendons, but nerves also, may be reunited and made to regain their function. Now, I commonly dress these cases by swinging the extremity by means of a very simple apparatus. I take a slate, or rather the framework of a slate, and to this I attach a pad of sawdust, on which the arm is laid. The arm is then swung by means of pulleys and a bar fixed over the bed, the arm of the patient being counterweighted by means of a graduated tin, filled with shot, so as to exactly balance the part suspended.

In this way the patient can, without an effort, raise or depress the part, and is even allowed sufficient liberty of movement to permit of his getting up and moving around his bed.

Now, although I thought I had made this man as comfortable as he possibly could be, yet he soon became irritable, and his temperature rose to 103° or 104°. There was nothing to account for this, save that he complained of the apparatus, and said that it irritated him. Now, I always attend to the com-

plaints of my patients, and you will always find they have some good reason, or at least, if not attended to, will make themselves ill over nothing at all.

Well, I had to take it all down, and laid his arm simply upon the bed. At once he was relieved, the irritation was at an end, and the temperature fell to the normal point.

Now, gentlemen, I pray you always to attend to the slightest complaints of your patients. If you do not, some slight irritation, such as I have been describing to you, will vex and continue to vex them, which at last may grow into such an irritation as to produce not merely pain, but considerable constitutional disturbance.

But these rough mechanical movements are not the only conditions which give rise to unrest in a wound. In these days, when we endeavor to secure union in a wound by first intention, we bring into close apposition the margins of the wound. But we know that in connection with all wounds there is a certain amount of blood-stained fluid necessarily effused, and if this remains locked up in a wound, what must of necessity ensue? Not only is the patient made restless, and pain occasioned by the swelling caused by the accumulation of the fluid, to say nothing of the risks of some one of those forms of constitutional disturbances which we speak of collectively under the name of blood-poisoning, but, as you can readily understand, the fluid, as it collects, of necessity separates more and more widely the parts, which, if they are to unite by primary union, or by granulation, must needs lie in absolute contact. Now, to avoid this cause of pain and irritation, all wounds must be effectually drained. It matters not what form of drainage-tube you may employ; sometimes a silver tube may be used, or a piece of elastic tubing, or a bit of cat-gut, or that which I very frequently employ, a strip of gutta-percha tissue carried through the depth of the wound; but in some way drainage should be effectually secured, so that all this fluid may have a ready escape, and thus free the patient from the irritation which would otherwise necessarily be induced.

I do not think we have ever sufficiently recognized the great importance of the truths respecting drainage, first enunciated by Chassaignac. I think we are largely indebted to him for introducing the subject to our notice, and of its vast importance I cannot too strongly speak.

As bearing upon this point, I may venture to tell you, that, with the large number of tumors which I have removed in our theatre during the last seven years, there has been but one fatal case.

Of all the breast operations we have lost only one. That, of the greater operations performed upon bone there has not been one fatal case during the same period. Of the amputations which I have performed during this period, which have been some eighty, I have lost only four cases, and one of these, I must in truth, confess, was lost from my own ill-treatment of the case. And here let me add, that I consider it most important that we should always look at home for faults; and before we condemn the constitution of the patient upon whom we operated, or the hospital surroundings, we should ask ourselves whether we may not have committed some errors of treatment by the avoidance of which a more favorable issue might have been attained. In illustration, I may mention, that, at a meeting of our Clinical Society, Mr. Cadge, of Norwich, one of our ablest provincial surgeons, referring to a projected rebuilding of the hospital in that city, in consequence of its unhealthiness, stated that he would not rest con-

tent until he had brought it into the same satisfactory condition as that which I related of St. Bartholomew's. A year later he was able to state, in a lecture published in one of our medical journals, *The Lancet*, that, during the twelve months previous, his practice had been free from pyæmia, and he had, I believe, no fatal cases of erysipelas.

These may seem to you as unimportant details, but I maintain that it is by attention to these that the success of your treatment and of the avoidance of pain will entirely depend.

We have at our annual meeting at St. Bartholomew's an old toast to the health and ease of our poor patients. So far as surgical operations are concerned, I think I may truly say that their health and well-doing is thoroughly insured. It is during their convalescence to guard our patients from pain that I think we should now strive, and I hope I may have made clear to you, at all events, some of the points which, if attended to, may insure also the accomplishment of this.

I really ought not to occupy more of your time, but, to comply with the request of Professor Sayre, I will make a few remarks upon the treatment of abscesses; and, in continuing my remarks, I am reminded of that which happened to me the other day, when I had placed before me some fourteen dishes, which constituted my dinner, and from which I had to complete that which is one of the most important operations of the day. I fear that, just as I was then embarrassed by the multiplicity of choice, so you also may suffer from having so many subjects crowded in so brief a time under your notice. The time is scarcely passed—indeed, if you will refer to any of the works on surgery of the present day, you will find it laid down as a rule that, when you have a patient suffering with an abscess developed in the course of some chronic disease, it is better to leave the abscess to pursue its course, carrying mischief among the muscles, and widely diffusing such mischief in distant parts of the body, because it is stated, that when such an abscess is opened there is risk of grave constitutional disturbance, and sometimes even of inflammation of the abscess sac, leading to blood-poison and to the death of the patient. At the best, the opening of such abscesses was held to be followed by such an increase of the discharge as rapidly to exhaust the patient, and thus to hasten the fatal result; and, no doubt, treated as these abscesses usually were, such consequences often ensued. I now have no hesitation in opening such abscesses, and I may say that it constantly happens that patients are admitted to the wards for the purpose of having such abscesses treated, and within a week or ten days thereafter are discharged, to be again out-patients, the abscess having been opened without the slightest constitutional disturbance or inconvenience to the patient. We effected this by what I have spoken of as hyper-distention—a somewhat barbarous expression, but I believe in medicine we are permitted to make use of such expressions. To effect this we make a lotion of one part carbolic acid to twenty of water, diluted at the time of its use by the addition of hot water, so as to bring its strength to one in thirty. An incision is now made into the abscess; I usually employ one of a crucial shape, about the size of a double-edged scalpel, and the lotion is injected with an ordinary syringe provided with an elastic nozzle. The pus having been first evacuated in the ordinary way, as much as will flow being allowed to escape, and as much more as can be got at being evacuated by means of pressure, as the fluid is forced in and the sac becomes distended,

the elastic nozzle expands and fills up the opening, and in this way almost any amount of pressure may be brought to bear upon the distention of the abscess cavity. When distended as far as possible, the lotion is allowed to escape from the cavity, and the injection is repeated again and again until it runs clear from the wound. We then know that the abscess has been thoroughly cleaned out. I do not say it is always possible to effect this, for sometimes we meet with exceptions to the general rule, and find that some muscle or tissue hangs, valve-like, over a portion of the abscess sac, and renders it impossible for us to force the fluid to the extreme limits of the cavity; but such is an exceptional condition, and can only be taken as referring to the general truth that all good rules must have their exceptions. After the distention has been completed, and the drainage-tube is introduced, and the wound is covered with some carbolized oil, lint, and a sheet of gutta percha tissue, there may be some little discharge, partly of the fluid injected and not evacuated at the time of the operation, which may be mingled with pus for a few days; but presently the abscess contracts to a mere sinus. I do not mean to say that this sinus can be always closed; the treatment does not profess to cure the carious condition upon which the abscess may depend; and so long as a cause of irritation exists, whether deep carious bone or dead bone, or whatever else may be the cause, the sinus will remain as a canal along which the discharge necessarily goes. But there will be no constitutional disturbance consequent upon the operation. All extension of the abscess is prevented, and the patient, so far from suffering, rapidly improves in his general condition consequent upon the evacuation which has been effected. If there be no such cause of irritation, the sinus will presently heal up.

In the case of acute abscesses the effect is still more marked. For example, a case which I recollect, that of a large abscess upon the side of the chest, consequent upon a local hurt; the hyperdistention of the abscess is followed by the rapid contraction and healing of the sac.

It so happened, that some time ago I had under my care a case in which two abscesses had formed in consequence of disease following the course of the vena saphena interna. Not disease of the vein itself, for I do not believe in such an occurrence. One of these abscesses was opened in the ordinary way, and it was three or more weeks before it healed. The second abscess I distended, and the result was, that in some two or three days it had entirely closed. I do not know when I have had a case which impressed me more with the benefits attending this particular method of dealing with abscesses, acute or chronic.

A NEW PHILADELPHIA DISPENSARY.—The building formerly known as the Retreat, on the Spruce Street side of the Pennsylvania Hospital grounds, in Philadelphia, was opened on January 1st, 1879, as a free dispensary for medical and surgical relief, free to all unable to pay for the same. The reception room is cosily fitted up, and there are two rooms besides for the medical and two for the surgical patients, with appropriate closets and washstands, the heating being from open grates. The hours for surgical treatment are from 10 to 11 A.M., and from 11 to 12 for medical relief. The dispensary will be open every day except Sunday, and visitors to patients will be admitted only on Mondays, Wednesdays, and Fridays, from 2 to 4 P.M.

LECTURES ON CLUB-FOOT.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK (SPECIAL COURSE).

By JOS. C. HUTCHISON, M.D.,

VISITING SURGEON TO THE BROOKLYN CITY HOSPITAL; SURGEON-IN-CHIEF TO THE BROOKLYN ORTHOPEDIC INFIRMARY; CONSULTING SURGEON TO THE KINGS COUNTY, ST. PETER'S AND ST. JOHN'S HOSPITALS, ETC.

LECTURE VII.

TALIPES CALCANEUS—CONGENITAL—TREATMENT—NON-CONGENITAL—CAUSES—TREATMENT—CALCANEO-VALGUS AND CALCANEO-VALGUS.

I invite your attention to-day, gentlemen, to another deformity of the foot, viz., *talipes calcaneus*, which, like the varieties hitherto described, occurs both as a congenital and non-congenital affection—the two varieties differing so greatly, both in pathology and treatment, as to demand a separate consideration. The congenital form is almost as rare as equinus. The essential characteristic of *talipes calcaneus* is depression of the heel. In the *congenital* variety, which we will first describe, there is, in addition to the depression of the os calcis, marked flexion of the dorsum of the foot against the front of the leg (Fig. 27), and

FIG. 27.

the condition is exactly the reverse of *talipes equinus*, in which there is an extreme degree of extension of the foot. The foot is retained in a flexed position by the contraction of all the muscles whose tendons pass over the front of the ankle-joint, and stand out very prominently.

The *bones* undergo very little change in their relative positions; indeed, the deformity is only an exaggerated degree of one of the natural motions or positions of the foot, and the deformity, in the infant, can be easily overcome by gentle manipulation; but on removing the hand, the foot is immediately drawn up again by the contraction of the muscles. The facility with which the foot can be brought to a normal position indicates that structural shortening has not taken place, either in the *flexor muscles*, or in the *ligaments* on the anterior part of the foot. In rare cases, however, the foot is held firmly in its flexed position in consequence of the structural shortening of the anterior muscles of the leg and the anterior ligaments, and operative proceedings may be necessary to overcome the distortion.

Prognosis.—Congenital *talipes calcaneus*, which is only seen in infants and young children, may be regarded merely as a malposition from intra-uterine pressure. It is the least important, as well as the rarest deformity of the feet, and yields readily to the simplest treatment. Surgical interference is not usually required. It is only necessary in ordinary cases to

extend the foot, to make frequent passive motions of the ankle-joint, and to use frictions with the hand over the anterior muscles of the leg. The cure may be hastened by the application to the front of the leg and foot of a well-padded metal splint, which should be straightened from time to time, as the foot improves.

In the rare cases in which there is permanent contraction of the flexor muscles (namely, the extensor longus digitorum, peroneus tertius, extensor proprius pollicis, and the tibialis anticus), they should be divided as they pass over the ankle-joint, where they are tense and prominent. A sharp-pointed tenotome is inserted close to the inner side of the extensor longus and carried outward beneath the tendon of that muscle, and also of the peroneus tertius, which are then divided towards the skin; the knife is withdrawn, and reintroduced and passed inward beneath the anterior tibial and extensor pollicis tendons, which are divided in the same way. You will avoid the risk of puncturing the anterior tibial artery by keeping the point of the knife close to the tendons to be divided. The wound should be immediately closed by a pledget of lint, retained by adhesive plaster and a bandage.

After three or four days you should begin the mechanical treatment, which consists in the application of the padded metal splint, in the manner which I have just described. The foot should be extended daily, and you will, in the course of three weeks, without much pain or inconvenience, be enabled to bring it to a state of complete extension. When this has been accomplished, the splint may be left off an hour or two each day, and passive motions and manipulations practised until the tendency to contraction has ceased. This is of the greatest importance also to the development of the infantile muscles. There is but little tendency to relapse, and in the after-treatment no retentive apparatus is required.

NON-CONGENITAL TALIPES CALCANEUS.

This deformity of the foot has been designated by one writer (Barwell) as *talipes curvus*, by another (Bauer) as *talipes simplex sive plantaris*, and by others it is described as *talipes calcaneus valgus*. I prefer to

FIG. 28.

describe it under the name of *non-congenital talipes calcaneus*, because of its resemblance, in the early stage, to congenital calcaneus, for, in addition to depression of the tuberosity of the calcis, there is, in the early stage, slight elevation of the anterior part of the foot (Fig. 28). At a later period, however, the foot becomes flexed upon itself at the transverse joint, the anterior portion is bent downward, the transverse arch is lost, while antero-posteriorly the sole is deeply arched. This affection is usually of paralytic origin, the paralysis being generally confined to the triceps surae, but sometimes it extends to all the extensor muscles. I

cannot better describe this deformity than by directing your attention to the appearances presented by the cast I here show you, which was taken from the

FIG. 29.

right foot and leg of a girl eleven years old, who was the subject of infantile paralysis, affecting the triceps extensor muscles of the leg, at two and a half years of age (Fig. 29). It will be noticed that the foot in front of the transverse tarsal joint is bent downward. The flexion of the anterior part of the foot is secondary, and is due to the action of the peroneus longus chiefly, assisted by the posterior tibial, these muscles supplementing the sural muscles as extensors of the foot. These muscles acting, while the triceps surae are paralyzed, in their efforts to keep the foot normal by their extending force, must necessarily drag down the anterior tarsus, so that the ball and the heel approximate each other, and the sole is so deeply arched that a mouse could run under it without touching it, as was the case in Lady Hester Stanhope's foot, which was remarkable for a high plantar arch. The transverse arch has disappeared. The foot is also a little rotated outward by the action of the peroneus longus, its farther rotation being prevented by the action of the posterior tibial. It will be perceived that the head of the metatarsal bone of the great toe is forcibly depressed. This is due to the normal contraction of the peroneus longus, which is unopposed in this part of its function. It will be seen also that the os calcis is depressed, so that the patient walks on the tuberosity instead of walking upon the normally under-surface of the bone, and that the only parts of the foot which touch the ground are the ball of the great toe and the tuberosity of the heel. The muscles of the calf are wasted, owing to the long-standing paralysis, and the back of the leg, from the knee downward, is very nearly straight, instead of presenting the curved outlines observed in the normal leg. Even the os calcis has lost its prominence, and the tendo Achillis feels like a thin and narrow ribbon. The limb is cold, the circulation languid, and the patient suffers easily from chilblains; in fact, we have here the usual concomitants of a paralytic limb.

You can imagine that the inconvenience caused by such an affliction is very great, and the lameness considerable; the relaxation of the ligaments deprives the foot of all useful motion and firmness, and walking is accomplished with great difficulty without the aid of artificial support.

The usual cause of non-congenital calcaneus is in-

fantile paralysis, principally confined to the sural muscles; but sometimes all the muscles below the knee are paralyzed, except those whose contraction produces the deformity. It may also be caused by improper union of the tendo Achillis after section or accidental rupture, by separating the ends too far before they had united, or it may be produced by the contraction of a cicatrix resulting from a wound or burn on the dorsum of the foot. A condition of the foot resembling non-congenital calcaneus is artificially produced among the Chinese women of the higher order by confining the feet by short shoes and improper bandages during infancy (Fig. 30).

FIG. 30.

It has been found, upon dissection, that the relative position of the bones is considerably changed. We have already alluded to the depression of the tuberosity of the os calcis, while its anterior part is elevated; and, as a consequence of this, there is a great obliquity of the astragalus, its trochlea projecting posteriorly, while the articular surface of the tibia is thrown forward upon the neck of the astragalus, and the anterior portion of its trochlea. The bones in front of the transverse tarsal joint are pulled downward by the action of the peronei muscles, diminishing the length of the foot, and increasing the longitudinal arch.

Owing to the changed position of the bones, the ligaments on the dorsum of the foot and behind the ankle-joint are elongated; those in front of the ankle-joint and those in the sole, together with the muscles with which they are connected, are contracted.

When the distortion arises from paralysis, and is of long standing, the muscles are in a state of atrophy and fatty degeneration, more or less complete.

The prognosis in cases of this deformity arising from paralysis is usually unfavorable, and our treatment can only be palliative. We can remove the deformity in a measure, but we cannot give power to the muscles.

Treatment.—In paralytic cases, if the patient is seen soon after the distortion has begun, we can not only prevent any considerable deformity by the use of suitable appliances, but muscular power can, in a measure, be restored by means of electricity or galvanism, heat, stimulating applications, rubbing, etc. The apparatus which I would advise is the one I here show you (Fig. 31, Tiemann's). It consists of two lateral side steels, carried up the leg and secured by a band around the calf, with a joint at the ankle. The anterior part of the foot is depressed, and the heel is elevated by a steel spiral spring placed on a pivot, and playing between brackets of the leg and ankle-stem. This apparatus I consider preferable to the india-rubber cords fastened posteriorly to the heel below, and to the calf-band above, so as to imitate the tendo Achillis. If, however, the latter apparatus should be employed, the spur projecting from the posterior part of the heel should be dispensed with

(because it is in the way, and liable to catch, especially when descending the stairs), and the cord fastened directly to the heel by means of a leather strap.

You may be surprised to learn that this affliction is usually overlooked in the early stage, and, when it is recognized and brought to the attention of the surgeon, considerable deformity has taken place. The earlier it is treated, the more readily is the distortion overcome. When, unfortunately, much time has elapsed before the deformity is discovered, there is marked depression of the os calcis and great increase of the longitudinal arch of the foot, and the ligaments and muscles have adapted themselves to the

FIG. 21.

altered condition of the foot, so as to give it a considerable degree of firmness, which enables the patient to walk quite well. In such a case, while physiological treatment and mechanical appliances may increase the usefulness of the foot, and may be used in appropriate cases, it is extremely probable that tenotomy would, on account of the paralysis of the muscles, allow the foot to dangle about and become almost useless, and render some mechanical apparatus indispensable. Operative treatment is less appropriate in this than in other forms of club-foot. In exceptional cases it may be necessary to divide the contracted extensor and other tendons, and the plantar fascia, and then proceed to extend and elongate the foot by the use of a Scarpa's shoe, and by pressure on the dorsum of the foot. When the distortion has been reduced, the patient may wear the shoe which I have just shown you, for the purpose of supporting the limb. I desire to warn you against exciting the expectations of your patient too much. He should be informed that the treatment can only be palliative—that there is no reasonable probability that the paralyzed muscles will regain their normal power.

In cases of talipes calcaneus, the result of non-union of the divided tendo Achillis or of too great elongation of the reuniting medium. Dr. Little advises incising the edges of the ununited tendon, or dividing the uniting medium with a tenotomy knife, and then approximating the ends by placing the foot in an extended position. In such a case he has known an abundant effusion of plastic material to take place, and firm union of the tendon at the end of two weeks.

When the distortion is caused by cicatricial contraction on the front of the leg or dorsum of the foot, such a treatment should be adopted as seems to be indicated in each particular case.

Calcaneus varus and *calcaneus valgus* are slight and unimportant modifications of talipes calcaneus. Their characteristics are sufficiently indicated by their designations, and the pathology and treatment are essentially the same as in the simple varieties, and do not therefore deserve separate consideration.

I have now, gentlemen, completed what I have to say to you upon the subject of club-foot, in accordance with the plan which I proposed for myself at the outset. No attempt has been made to treat the subject exhaustively, or to amuse you with novelties, and I have endeavored to avoid *ad captandum* or random statements. It has been my purpose to give you in as concise and simple a manner as possible the results of my personal observations and reflections upon the subjects we have considered, to unfold to you, as I stated at the outset, a much neglected, but a most attractive chapter of modern surgery, and to impress upon you general principles which I trust will enable you to treat club-foot wherever you meet it, without the assistance of the specialist or the hospital surgeon.

To those of you who may desire to study more fully and more in detail the subject of talipes, I would recommend the great work of Mr. William Adams, of London, by far the ablest monograph upon this subject in any language.

In conclusion, gentlemen, I desire to express my sincere thanks for the interest you have manifested and for your uniform courtesy, and to wish you every success in the profession of your choice.

ACUTE ARTICULAR RHEUMATISM.

TWO LECTURES DELIVERED BEFORE THE MEDICAL CLASS OF THE UNIVERSITY OF PENNSYLVANIA,

BY ALFRED STILLÉ, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE.

(Reported for THE MEDICAL RECORD.)

LECTURE I.

THE CAUSES OF ACUTE ARTICULAR RHEUMATISM—TRUE ARTICULAR RHEUMATISM NOT A TRUE INFLAMMATION—GONORRHOICAL RHEUMATISM NOT A TRUE FORM OF ARTICULAR RHEUMATISM—COLD AND DAMPNESS AS EXCITING CAUSES OF ACUTE ARTICULAR RHEUMATISM—ACUTE ARTICULAR RHEUMATISM AS PRODUCED BY THE PRESENCE OF LACTIC ACID IN THE BLOOD—ACUTE ARTICULAR RHEUMATISM DUE TO BLOOD-POISON—THE LOCAL SYMPTOMS OF ACUTE ARTICULAR RHEUMATISM.

ACUTE articular rheumatism is one of the most common of all diseases. Although but rarely, if ever, fatal in itself, it is always liable to cause permanent deformity, and is often followed by serious and destructive complications. You all know, indeed, that it is one of the most potent and frequent causes of organic disease of the heart. Its presence is marked by pain, swelling, heat, and redness, the usual signs of the inflammatory process. These symptoms manifest themselves in one or more of the joints. Though in all instances accompanied by fever, there is but slight, if any, tendency to suppuration. As far as I am concerned, I have never known of suppuration to occur in this disease. This fact shows us conclusively of itself, if we had no other facts as proof additional, that acute articular rheumatism is not an inflammation in the ordinary sense of the word. The patient may recover entirely, so far as the joints are concerned, and yet die from one of the numerous complications of the disease. Acute rheumatic inflammation of the joints seldom leaves behind it the results of inflammation in the joints themselves, no matter how severe may have

been the attack. When lesions of the joints have been found after death, and such cases are of exceeding rarity, they have undoubtedly been the result of an arthritis due to other causes, such as pyæmia, and by pyæmia I mean a general blood-poison, accompanied by a tendency to suppuration all over the body, in the joints as well as elsewhere.

TRUE ACUTE ARTICULAR RHEUMATISM NOT A TRUE INFLAMMATION.

Now, perhaps some of you may be surprised that I should speak in this way, and you may say to me, "You have not always taught us this." Very true; I must confess that my past teachings have been far from my present convictions on this point. I have been compelled to waver, because those whom I am bound to consider as my own teachers have held at different times, within recent years, the most various and contradictory views of this matter. But, with the better and more conclusive light which has quite lately been thrown upon the subject, I am to day able to give you my complete and final judgment in the matter, which is, that in *acute rheumatism of the joints there is no true inflammation, in the proper sense of the term.*

Acute articular rheumatism is said by some to be an hereditary disease. I have always had, and still hold to, my doubts as to whether it ever occurred without the intervention of a direct cause, such as cold and dampness, poor food, and improper clothing. Of course, these conditions are most frequently met with among the lower classes of society, and the children of these people, being exposed to the same predisposing causes as their parents, are subject to the same disease, and yet it would be far from logical to state that such children acquire the disease from a simple inherited predisposition to it.

One thing, however, is very certain, and that is, that a person who has had one attack of acute articular rheumatism is much more liable to a second attack than he who has not been attacked before. One attack is wont to leave behind in the system a great susceptibility to the disease and to its cause. One who has suffered from acute articular rheumatism will always feel the approach of cold and damp weather, and will, as it were, become his own barometer.

Although attacking children frequently, it is comparatively rare until the age of puberty. It frequently follows dysentery and scarlatina. Every now and then we see it in the puerperal state. I can imagine no common element which is able to account for its presence in each of these three conditions. The diseases themselves are certainly widely different.

Males are much more susceptible to the disease than females. And this is so, of course, because they are much more exposed to the vicissitudes of weather than the gentler sex. This rule holds good in this country among all classes of society, and in England and the continent, among the middle and upper social strata; but where the women perform the same outdoor labors and are consequently as much exposed as the men, which is the case almost universally among the lower classes in Europe, they do not differ so much from the men in the frequency of being attacked.

Certain classes of people, owing to the nature of their employment, are the most exposed to the disease. Of all persons, sailors are proverbially the most rheumatic, and with good reason. Next in order come soldiers on active campaign duty. Among trades, bakers, going as they do, in a moment from a very hot to a more or less cold temperature, and dyers and coachmen, and in fact, outdoor laborers of all kinds are much exposed to the peculiar conditions which

produce the disease, and are of a necessity more subject to it than others.

You have heard, no doubt, of gonorrhœal rheumatism?

GONORRHOËAL RHEUMATISM NOT A TRUE FORM OF THIS DISEASE.

I have great doubts as to whether rheumatism of the articular type can be produced without the interference of cold. Gonorrhœal rheumatism is not a rheumatism in its true sense. Those who hold that it is so are, I think, in much error. Gonorrhœal rheumatism is a species of synovitis. Such are those rare, so-called cases of acute articular rheumatism in which lesions have been found in the joints after death, to which I directed your attention a few moments ago.

COLD AND DAMPNESS AS EXCITING CAUSES OF ACUTE ARTICULAR RHEUMATISM, WITH AN EXPLANATION OF THEIR ACTIONS.

The great exciting cause of acute articular rheumatism is cold, especially when the body is perspiring; hence, where east winds prevail, rheumatism is rife. Rheumatism is very frequently met with in the British Isles, because the climate is so cold and damp. In America, the further you recede from the influence of the east winds the less rheumatism you will find.

There has been much discussion regarding the rationale of the action of cold and dampness upon the body in producing this disease. Cold, of course, tends to carry away caloric from the body, while dampness not only deprives the body of caloric and of electricity, but also exerts a depressing influence upon all the functions of life. Not only do the cold and dampness carry away these vital stimulants, but they prevent exhalation, and so cause the retention of effete material within the body. (I shall allude hereafter to the theory of the presence of a poison in the blood in this disease; but you can very easily see how, if exhalation from the surface of the body is prevented, there is of necessity a poison retained and circulating in the blood.) Many of you have noticed, no doubt, how much more tolerable is a really intense degree of dry cold than a much less degree of damp cold.

Cold and dampness act more upon the joints than upon other parts of the body, *i. e.*, affect them sooner, because the joints are not protected by muscles and fat, and have less blood and therefore less heat in them.

Cold, as you know, always produces a temporary suppression of habitual discharges, such as the menses, the flow of milk, and the secretion of pus. Whatever produces a suppression of discharges may, of course, bring on articular rheumatism; but cold and dampness, when they check such discharges, always produce it. This disease, as is well known everywhere, is infrequent in warm weather. In countries where the temperature is always high, it is hardly ever known to occur. This would seem to be quite sufficient proof of the powerful effect of cold and dampness in producing it.

ACUTE ARTICULAR RHEUMATISM AS PRODUCED BY THE PRESENCE OF LACTIC ACID IN THE BLOOD.

It is very hard to know exactly how cold and dampness produce acute articular rheumatism. There have been very many attempts made to explain the real and direct cause of the disease, but none of the theories advanced have been consistent with all the facts of the case, *i. e.*, have so far explained away the difficulties of the situation as to constitute themselves

trustworthy explanations. One theory, however, stands preëminent among all the rest as clearing up very many dark points. This theory is of quite recent origin, and is, that the phenomena of acute articular rheumatism are all caused by the accumulation and the retention of lactic acid and of other acid products in the blood. Certain it is that these acids must be retained in the blood if the elimination of effete products is checked.

One well-authenticated fact makes this theory, in semblance at least, a very plausible one. Large doses of lactic acid, as given to patients with saccharine diabetes, occasionally produce all the symptoms of acute articular rheumatism. The administration of lactic acid, as you all know, in saccharine diabetes, causes an immediate and most marked reduction in the quantity of sugar in the urine. In one case on record, this same treatment was seen to produce all the symptoms of acute articular rheumatism several times in succession. Dr. Foster, of England, had under his charge a patient with well-marked symptoms of diabetes, who was treated with lactic acid, and most carefully watched. This patient had never suffered from an attack of acute articular rheumatism, and had been in the hospital under treatment for diabetes for some time before the lactic acid was employed. No sooner had several doses of the lactic acid been administered than the man began to complain of pains in the joints, while the joints themselves became swollen, red, and painful to the touch. Upon the inception of these undoubted symptoms of acute articular rheumatism, the use of the lactic acid was suspended, and, no other treatment being employed in the meantime, the symptoms aroused by the use of the acid gradually, but completely, disappeared. Again the acid was administered, and again the redness, swelling, pain, and heat in the joints came on—only to disappear for the second time upon the suspension of the drug. A third time the medicine was given—a third time the same symptoms came and disappeared. Whether the remarkable and consistent effects of lactic acid in this case of Dr. Foster's show any real and palpable connection between the assumed cause of the disease and its real cause, whatever that may be, I do not, indeed, know; but of one thing I can be absolutely certain, and that is, that the lactic acid in the above cited case at least, if not in ordinary cases of acute articular rheumatism, directly produced the actual symptoms peculiar to acute articular rheumatism.

The acidity of the blood in this disease has been conclusively proven to be greater than in any other affection, while the salutary and immediate effect of the administration of alkalis in its treatment gives additionally strong support to the idea that all the trouble is caused by the over-abundance of some acid in the circulation, whether that acid be lactic acid or not.

Attention has been called to the fact, that while one person exposed to cold and dampness is seized with acute articular rheumatism, another individual, after exactly the same exposure, may have an attack of dysentery, etc., etc., and the conclusion has been drawn that cold and dampness are not important factors in the causation of the disease. You should all know that one person may have a decided predisposition to one form of disease, while his neighbor is equally strongly predisposed to another of a widely different nature, and that when these two persons are exposed to cold and dampness, the great exciting causes of many different diseases, one is attacked with one, and the other with another disease.

The early symptoms of acute articular rheumatism are those of all other diseases which are attended with the symptoms of inflammation, viz.: a chill, a feeling of general debility, a hot skin, a frequent pulse, loss of appetite, headache, thirst, and more or less highly colored urine. None of these conditions are distinctive of this or any other form of acute disease. The joint affection is *the* symptom; soon after the above prodromic phenomena have set in the joints, one or more of them, or all of them simultaneously, become swollen, red, and painful.

Occasionally the local symptoms precede the constitutional, *i. e.*, the joints become swollen, red, and painful before the fever, and headache, and general lassitude are felt. But, as a general thing, the fever and the other attendant symptoms are the first to appear.

If the symptoms were merely local, or always primarily so, the disease would be only a local disease. But the first occurrence of general symptoms which sometimes occurs, points indubitably to the existence of blood-poison.

ACUTE ARTICULAR RHEUMATISM DUE TO BLOOD-POISONING.

There is no question about this. It is proved beyond all cavil by what I have just told you of the causation and symptoms of the disease. *Rheumatism* means, etymologically, *a defluxion of some humor upon the joints*. This old definition is confirmed by the most recent researches. It is a general systemic disease, which assumes a local form.

THE LOCAL SYMPTOMS OF ACUTE ARTICULAR RHEUMATISM.

Pain is the first local phenomenon. This pain may amount only to a simple feeling of tension, or it may be lancinating, or throbbing, or boring; of whatever kind the pain may be, in its degree it is often intolerable. There is no other pain of the joints, except that of gout, which is worse than that of acute articular rheumatism.

The pain is felt most upon motion, *i. e.*, upon movement of the part. The least movement, a breath of air, a touch of the bed covers, produces the most violent exacerbation of pain. The pain too is always worse at night. The inflammation has a great tendency to leave its seat and migrate to another joint, or to all the other joints at once, or to one of the internal organs. Herein lies another proof that we have no local disease to deal with. Again, the disease may leave one joint altogether, and settle upon another joint, or upon an internal organ, and then, leaving this second point of disease, return again to its first seat. Again, all the joints of the body may be the seat of the disease, and the patient become as rigid as a statue.

It is a strange fact that the disease, when leaving one joint and seizing upon another, is likely to attack the same joint upon the opposite half of the body, or if two joints are simultaneously affected, they are apt to be the corresponding joints on the opposite sides of the body.

The next symptom which we have to consider is the *heat*. This is very sensible to the hand when applied to the affected parts. The temperature is never so high, when but one joint is affected, as when all the joints are attacked simultaneously. In ordinary cases the thermometer applied to the skin marks from 100° to 104° F. In exceptional cases—particularly the so-called cases of *hyperpyrexia*—the temperature runs up to 110°, or is sometimes even as high as

112. (It is in these cases of so-called hyperpyrexia that a certain kind of treatment is supposed to be valuable on account of its power of reducing the temperature.)

The *redness* is never so great in acute articular rheumatism as in other forms of inflammation—seldom being more than a light pink.

The *swelling* likewise is not so marked, but as it occurs in the joints is easily detected—particularly in this the case where the ankle, elbow, or knee-joint is affected. In the case of the hip joint, there may be a considerable amount of swelling around the joint without any external sign of its existence. This is also the case in rheumatism of the vertebrae, where the swelling is generally of a diffused nature, and not marked on the surface.

The swelling is generally of two kinds, occupying (1) the connective and other tissues around the joints, or (2) attacking the tendinous fosse or the synovial cavities. In this latter form, the joint may become lobular in shape, and percussion may elicit considerable fluctuation, and give to the patella a regular sea-saw motion as it hangs suspended in the fluid.

(To be concluded.)

COOK COUNTY HOSPITAL, CHICAGO.

CLINICAL REMARKS

BY EDWARD W. LEE, M.D.

(Reported for THE MEDICAL RECORD.)

DIFFUSE TRAUMATIC ANEURISM OF THE PALMAR ARCH.

We have here a case of diffuse traumatic aneurism. Some eight weeks since this man sustained a wound in the palm of the hand by means of a piece of broken glass. The wound healed kindly and he thought nothing more of it till about a month subsequently, when he noticed a small pulsating tumor making its appearance at the site of injury; it gradually increased in size till it became as large as a walnut. One night during sleep it ruptured, and a considerable quantity of blood was lost. A compress was applied, which controlled the hemorrhage. I examined the injury for the first time about forty-eight hours since. On removing the bandage and compress the blood spurted out with great force, so that I was obliged to make forcible compression on the radial and ulnar arteries in order to control the hemorrhage. I do not know of any lesion the treatment of which proves more troublesome, or taxes the skill and patience of the surgeon more, than this. The bleeding-point was at the deep palmar arch as it gives off its first interosseous branch; from its depth it was a matter of great difficulty, without making such an extensive dissection as to endanger the integrity of the hand, to reach it, and as the soft parts had become pulpified by the pressure of the tumor, the difficulty was still further enhanced. It is always the best practice, if it can be accomplished, to secure the vessel at the seat of injury, as you may ligate the radial and ulnar arteries; yet the anastomotic supply furnishes sufficient blood to maintain the hemorrhage. I made a longitudinal incision over the centre of the tumor, and turned out the clots and broken-down tissue; this procedure made quite a good-sized cavity, at the

bottom of which the bleeding vessel could be seen. Repeated efforts were now made to ligate the injured artery, but without success. I, however, made acupuncture by means of a curved needle passed beneath the vessel at the proximal side, and in this manner succeeded in controlling the supply of blood from that direction. An attempt to execute a similar manœuvre on the distal side was unsuccessful, for want of a needle with a suitable curve. I found a tenaculum, however, which possessed the requisite curve, and, by passing it under the vessel and compressing the transfixed tissue with silver wire, I succeeded in controlling the hemorrhage completely. So great had been the difficulty in attaining this object by *any* means, I thought it would be imprudent to disturb the existing order of things, and so determined to leave the tenaculum in situ. The handle of the instrument was protected with wads of oakum and a bandage applied over all—rather a cumbersome-looking dressing, as you may perceive, yet thoroughly effectual. I shall leave it undisturbed for two or three days, when it may be removed with perfect safety.

ANTISEPTIC DRESSING WITHOUT THE SPRAY.

The next case we have illustrates what we may do with many small wounds in the way of antiseptic dressing, dispensing with the spray, gauze, etc., as used in the Lister method. This young man received three weeks ago a crushing injury of the hand. The index finger received a lacerated wound, the middle a compound fracture, and the ring finger was so badly mutilated that amputation was rendered necessary. The injured parts had been exposed to the atmosphere for a couple of hours before the first dressings were applied. I carefully cleansed the wounds, then thoroughly washed them with a solution of carbolic acid (15 grs. to the ounce of fluid made of one part each of alcohol and glycerine and six of water); then, with lint steeped in this solution, I wrapped the injured fingers, securing them with a narrow roller bandage neatly and closely applied, so that the dressing was quite thick. The dressings were again saturated with the solution, and directions given to keep them constantly moistened with it. The patient was seen daily and carefully examined for evidences of suppurative inflammation. In the absence of such the dressings were allowed to remain on a full week, and then their removal was simply a precautionary measure, as I believe they might have been allowed to remain undisturbed to this day, with positive benefit. Not a drop of pus was visible; healing had progressed kindly. The dressings were renewed. Another week passed by: still no evidence of suppuration. The wounds were again dressed as before, the same healthy condition being found. The finger least injured was nearly healed. Three full weeks have now passed by, and for the third time I shall remove the dressing. From the length of time that has elapsed and the exposure of the wounds to the air, it would seem reasonable to expect to find some pus this time. As I remove the bandages you perceive no pus is present, and the wounds are in a perfectly healthy condition.

In adopting this modified antiseptic plan you should watch the case very closely: if you find pain has been experienced running up the limb, or that heat is complained of in the part—if fever or glandular and lymphatic irritation is present, you must immediately remove the dressing. On the other hand, in the absence of all those symptoms, you may permit them to remain undisturbed. I have before now dressed a compound fracture of a finger in the manner detailed, and, guided by the symptoms, permitted the original dressing to

be retained full thirty days; on removing it at the end of that time, I found the bone fully united and the wound healed.

This mode of treating wounds may be very beneficially used in all small injuries where it is inconvenient or impracticable to use the perfect process with the spray, etc.

One improvement upon the dressing used in this case might be made. The bandages after they are applied should be painted over with a solution of some gum or resinous tincture, to make the dressing more nearly air-tight. Compound tincture of benzoin, or tincture of tolu, will answer the purpose.

Progress of Medical Science.

ON THE PULSATION OF THE VENA CAVA INFERIOR IN ITS RELATION TO PATHOLOGICAL CONDITIONS OF THE LIVER.—Dr. Ludwig Diemer has demonstrated the existence in rabbits of a physiological pulsation of the vena cava, isochronous with the contraction of the right auricle. It is not appreciable at the point where the renal veins open into the cava, and is very slight at the level of the openings of the hepatic veins, but it is very distinct in the thoracic cavity close to the heart. A possible error from compression by the diaphragm was excluded by division of that muscle. When the vein was compressed below, and then artificially emptied by pressure toward the heart, it was quickly refilled by blood from the heart. This regurgitating wave in the cava inferior is very small in consequence of the aspiratory action of the cardiac diastole. When the circulation in the pulmonary artery is impeded in consequence of valvular lesions or of disease of the lungs, resulting in increased pressure in the right ventricle during diastole, the blood is dammed back in the cava inferior, and disease of the liver follows (nutmeg liver). Dr. Diemer accounts for the fact that the kidneys do not suffer to an equal extent with the liver from the retardation of the circulation in the cava ascendens, by the theory that it is the pulsation and not the retarded circulation itself which is the immediate cause of the atrophy of the liver. A further increase in the obstruction is followed by an increase in the force of the venous pulsation, and the kidneys then become hyperæmic, but the right more so than the left, because it lies nearer to the liver.

In men the vena cava is directly in contact with the liver, and the distance thence to the heart is still smaller than in rabbits. Dr. Diemer thinks that foreign bodies which enter the right side of the heart with the blood, may be carried into the cava inferior, and thus into the liver by the regurgitating blood-stream (Magendie, Merkel). In this way the often asserted connection between injuries of the head and abscesses of the liver, the lungs remaining intact, and the predilection of metastatic carcinoma for the liver may be accounted for.—*Med. Chir. Rundschau*, August, 1878.

ON INSOLATION AND REFRIGERATION.—Dr. Kirchner has recently carried out a series of experiments on animals with a view to gain an insight into the pathogenesis of the two allied processes, insolation and refrigeration. He deduces from them that the latter may be characterized as prostration of the vital forces, and, first of all, of respiration and circulation. The morphotic and chemical alteration of the blood resulting therefrom, particularly its impoverishment in

oxygen, is the immediate cause of the derangements that directly threaten life. Warmth, on the other hand, acts as an irritant on the animal organism, and when in excess leads to exhaustion. This constitutes the essence of insolation. As in the case of refrigeration, the foundation of the symptoms is the exhaustion of the oxygen of the blood, which here too is the consequence of the failing respiration and circulation. The appearance of rigidity during exposure, either to cold or heat, indicates excessive lack of oxygen in the blood. This rigidity is, like the rigor mortis, an anæmic muscular tetanus. If, however, we put coagulation, or, in other words, coagulation of the muscles, out of the question, tonic muscular rigidity is not commonly met with in cases of refrigeration or insolation.

The deleterious action of extreme temperatures on the organism is heightened by other weakening influences which tend to impair the supply of oxygen and to exhaust the resisting power of the system. Here must be mentioned, particularly, the misuse of alcohol. In addition to these acute effects of the action of cold and heat, there are analogous chronic conditions, which must be ascribed to the gradual action of extreme temperatures in the organism. They are characterized by manifestations of anæmia and exhaustion, and in their higher grades partly constitute the basis of the tropical and polar cachexias. It is still an open question whether any other specific diseases owe their origin to the influence of heat and cold. The fact that abdominal typhus occurs most frequently during the latter part of summer and towards the end of winter, has not yet been satisfactorily accounted for; and, as in many cases, no external source of infection can be discovered, it is, in fact, possible that the morphotic and chemical alterations of the blood and tissues, which have been proved to be the pathological effects of insolation and refrigeration, play at least a subsidiary rôle in the production of the infection.—*Allg. Med. Cent. Zeit.*, No. 47, 1878.

OBSTINATE VOMITING CURED BY MEAT-PANCREAS INJECTIONS.—In the case of a woman, forty-eight years of age, suffering from an abdominal aneurism, the vomiting was so persistent that the patient was unable to retain even a mouthful of water on her stomach. Dr. Düring, of Westhofen, under whose care she was, finally had recourse to Leube's nutritive clysters. Every day, 1½ oz. of meat and ½ oz. of pancreas were chopped up very fine and mixed with warm water, until the compound had the consistency of a thin pap; half of this was injected into the rectum in the morning, and the other half in the evening, the clyster being retained each time for from eight to ten hours. The nutrition of the patient soon began to show signs of a slow improvement. After three weeks she was able to take a little milk by the mouth, but as the quantity thus taken did not exceed four table-spoonfuls per diem for several weeks, the progressive improvement could only be ascribed to the injections. After ten weeks the patient was so far improved that the clysters were discontinued. The gradual improvement in stomach digestion was accompanied by a progressive diminution in the size of the tumor.—*Med. Chir. Rundschau*, August, 1878.

PECULIAR ALTERATION OF THE EPIDERMIC CELLS.—Dr. Leloir, of Paris, has met with a hitherto undescribed form of morbid alteration of the epidermic cells. He observed it first in venereal vegetations, but has subsequently met with it also in mucous patches of the labia and in epithelioma of the glans. The cells affected are chiefly those of the intermediate

layer of the epidermis, but the more superficial cells of the rete, and the deeper cells of the horny layer are also involved. The change consists first in the formation of a cavity around the nucleus; this cavity gradually enlarges at the expense of the protoplasm, while the nucleus at the same time undergoes various changes. As the cavity enlarges the protoplasm loses its granular character, seems to become striated longitudinally, and is converted into a thin cell-wall; the serrated border is lost. At the same time the nucleus in many of the cells has broken up into a number of granules, which are strongly colored by carmine, and which may finally disappear entirely. In other cells, on the contrary, the nucleus proliferates. Hence, while some of the newly-formed cavities are empty or contain only a few granules, others contain two or three nuclei, or perhaps a single nucleus in process of division. It is probable from this that a portion of the embryonic elements and leucocytes, met with at a more advanced stage of the process, are derived from the nuclei of the epidermic cells, a mode of origin which is absolutely denied by Auspitz and Unna.

As the process advances the cellular walls become thinner and thinner, and at last break down entirely, and the cavities open into one another. In this way vast spaces are formed, whose walls present irregular projections, constituted by the debris of the cellular walls. These spaces are filled with nuclei, white globules, granules, and small filaments, crossed or otherwise, the remains of the walls of disintegrated cells. At this stage the appearance of the section is exactly like that of a variola pustule.—*Gazette Médicale de Paris*, No. 24, 1878.

NOTE ON THE EPITHELIUM OF THE SUDORIFEROUS GLANDS.—Most authors who have written about the structure of the sweat-glands, have merely stated that the epithelium in the convoluted portion of the tube is composed of polygonal and cylindrical cells. These cells rest on a special membrane, on the internal surface of which Czerny asserts that he has found an endothelial lining. M. Renaut, however, has found that the cells of sweat-glands, taken immediately after death from the same region of two animals of the same species, often present very remarkable differences. He cuts out a small piece of the skin of a freshly slaughtered animal, and immerses it in strong alcohol, which hardens it so rapidly that thin sections can be cut on the following day. In skin taken from glandered horses slaughtered early in the morning at the moment of leaving the stable, when consequently the skin had not been in a state of free perspiration for several hours, he invariably found the epithelium of the sweat glomeruli composed of cylindrical cells, with clear protoplasm, the nucleus being located near the base. These cells resemble exactly, except in point of size, those which line the culs-de-sac of a conglomerate gland, such as the submaxillary. At first sight they might be mistaken for chalice cells, but the superior opening of the chalice is entirely wanting. The transparent portion of the cellule contains at the periphery a few granules, which are sometimes arranged in parallel lines so as to simulate a longitudinal, protoplasmic striation. If, however, the skin be taken from an animal killed after prolonged vivisection, or that has been placed under any other conditions which favor diaphoresis, the aspect of the epithelium of the sweat-glands is very different. The clear portion of the cellule no longer exists, the protoplasm having become everywhere granular. The swollen nucleus occupies the centre of the cell. Final-

ly, if the action of the coagulating reagent has been rapid, the lumen of the tube is found filled with the secreted liquid, which has solidified in the form of a homogeneous mass, resembling in appearance lymph-clots.

It results from these observations that, as in the agminated glands, where long-continued secretion modifies the form of the glandular cells, diaphoresis also changes after a certain time the constitution of the cells which line the convoluted portion of the sweat-glands. When portions of the human skin are subjected to a histological examination, the epithelium of the sweat-glands is, in the majority of the cases, found altered by the abundant diaphoresis which accompanies the agony and precedes death. The state of these glands is most frequently analogous to that of the submaxillary gland after prolonged irritation of the chorda tympani.—*Gazette Médicale de Paris*, No. 24, 1878.

CHANGES IN THE STRIATED MUSCLES IN PHTHISIS.—Dr. Fraenkel, of Hamburg, made careful microscopical examinations of the general muscular system in fifty-four cases of phthisis that died in the General Hospital in Hamburg last year, and has arrived at some interesting results. Macroscopically, he found that the muscles, as a rule, did not differ in appearance from normal muscles. Microscopically, however, the changes were very striking. The contractile substance presented all possible variations, from simple indistinctness of the cross striations to complete change of the contents of the primitive bundles into a finely granular mass. These appearances coincided with those previously found by Dr. Fraenkel in the laryngeal muscles. The most extreme form of alteration, however, that of empty sarcolemma sheaths, presenting only traces of molecular matter here and there, was much less common in the muscles of the body generally than in those of the larynx. Not unfrequently the contractile substance was found separated from the sarcolemma, the latter running a straight course, while the former presented an irregular, contracted, spiral outline. This condition was sometimes observed throughout the entire length of a primitive fibre, so far as it could be followed in the field. Transverse fissures in the muscular fibres were very frequently met with. One very constant change in at least a certain number of the muscles, notably the adductors of the thigh, the diaphragm, and the muscles of the eye, was the appearance of pigment in them. This pigmentation has not been observed in the laryngeal muscles. It appeared in the form of small, punctate, yellowish brown or greenish yellow granules, which were sometimes scattered through the contractile substance, giving it a peculiar dust-flecked appearance, and sometimes collected in small heaps about the normal or altered muscle-nuclei. The changes are not met with in equal intensity all throughout the body, some groups of muscles being much more severely affected than others. The following is the order given by Fraenkel: 1. Muscles of the eye, arm, and forearm. 2. Breast and neck. 3. Masseter. 4. Ball of the thumb. 5. Abdomen. 6. Back. 7. Leg. 8. Thigh and diaphragm.—*Wjg. Med. Cent. Zeit.*, July 20, 1878.

THE SOUTHERN CLINIC.—We notice that the *Southern Clinic* used our report of the meeting of the Public Health Association, and acknowledges its indebtedness very gracefully. We are always very happy to be of such service to other journals, especially when, as is not always the case, the credit is given to us.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, January 11, 1879.

THE YELLOW-FEVER INVESTIGATION.

THE board of experts on yellow fever, appointed by the Joint Committee of the Senate and House of Representatives, has been organized and has fairly commenced operations. The plan of procedure agreed upon gives an assurance from the start that the Commission thoroughly appreciates its responsibilities, and is ready and willing to act up to them. No better indication of this disposition can perhaps be given than the determination to utilize the work already accomplished by the Yellow-Fever Commission of the Public Health Association, and to make it the basis of future action by the board. Apropos to this remark, we may state that we learn for the first time what has been accomplished by that Yellow-Fever Commission during the past three months and up to the period when the majority of its members became members of the Board of Experts. At the time of the meeting of the American Public Health Association, the report of the Commission was one of progress only. As was to be expected, the Commission had no time nor opportunity for the digestion of the large number of facts bearing upon the cause and prevention of yellow fever, which had thus far been gathered. The report, at best, was but a presentation of facts without conclusions, a body without a skeleton.

No one who knew the men who composed the committee could think that they did justice to themselves, or the cause which they represented. Since the meeting in question, however, order has been brought out of chaos, the results of the investigation are being systematized, topographical and sanitary maps are being made, and a proper foundation is laid for an intelligent and comprehensive continuation of the investigation. Twenty-eight of the infected cities and towns have already been visited by the former Commission, and all important conditions and circumstances bearing upon the epidemic carefully studied, and the facts recorded. Inquiry has been made into

the circumstances attending the appearance of the first cases of yellow fever in each of the places visited, and the connection, if any, between the first cases and those subsequently developed. This line of inquiry has been pursued with reference to "each case of fever which occurred up to the time when the disease became epidemic, or so prevalent in the place as to be no longer instructive."

These inquiries referred for the most part to local or foreign origin, to the conveyance of the contagious principle, to the effects of quarantine, to measures of disinfection, to local influences as affecting the severity of the disease, to measures of individual prophylaxis, to the modification of other diseases by the epidemic, and to any unusual forms of disease during the epidemic.

We are also informed that maps have been prepared showing the location of each case of yellow fever which occurred, "with distinctive marks for recoveries and deaths." For New Orleans, five such maps have been drawn, each one exhibiting an epoch in the epidemic.

Tables representing the leading features of all epidemics of the country, as compared with the epidemic of 1878, are also being prepared, showing "the date of the first imported and first refugee case, and of death; date of first case and of first death among inhabitants; the date of occurrence of the maximum number of cases in one day, and said maximum number; date of last case, total cases, total deaths, total population, and number of persons who fled."

It seems to us necessary that we should present the work of the former commission in more or less detail, in order that the intentions of the Board of Experts, in continuing the said work—and on such a basis enlarging its investigations—may be the better understood. Not only on this account do we take the opportunity for presenting these facts, but, as before intimated, for the additional reason that they for the first time have been given to the public, being part of the report of the sub-committee appointed by the Board of Experts to devise a plan of organization.

Aside, then, from making the work of the former Commission available, the Board of Experts intends to enlarge the scope of its inquiries in several directions. There is to be made, for instance, a careful study of the meteorological phenomena during and between the epidemics, of the geological conditions, character of soil, the forms of vegetable growth, of the existence of decaying vegetable matter, of the condition of the blood and excretions, and of the "effects of the yellow fever upon the health of the people following the epidemic." It is also considered important that experts should visit the West Indies and Mexico for the purpose of inquiring "into the causes which keep alive and propagate the yellow-fever poison in these countries, especially in Havana, from which place it is usually imported into the United States." In order

to systematize this work, the board divides itself into sub-committees for special lines of investigation.

It would appear that everything has been done to secure the best results. Congress has voted a liberal allowance of money, has invested the board with full power, and has so harmonized the interest of the past fever commission with those of the present by the appointment of Dr. Woodworth as its chairman, and by retaining the majority of the former members, that there leaves nothing to be desired in the way of effective organization. Aside from this, the board itself seems to be so thoroughly alive to the duties of the hour, and takes such a comprehensive view of the situation that it is difficult, if not impossible, to offer a new suggestion as to what more could be done.

THE PREVALENCE OF SCARLET FEVER, AND THE PUBLIC SCHOOLS.

For the past two weeks the cases of scarlet fever have been so numerous in some parts of the city that fears are entertained of an epidemic. The type of the disease is more malignant than it has been formerly, and the mortality is increasing accordingly. Diphtheria is also assuming a graver form, and the number of deaths are proportionately increased.

Of course the various means which should be used to check the spread of these diseases suggest themselves to every one. The Health Board is concerned as to what can be done in that direction. There is no doubt that extraordinary precautions have been taken to guard against the spread of either disease. Naturally we look to the public schools as the proper places in which an initiative may be taken. We cannot expect anything from the Board of Education; in fact, even with a disposition so to do, it would be entirely incompetent either to advise or direct as to the course to be pursued.

The Health Board should be competent in cases of emergency to include the public schools in its jurisdiction. There is no doubt that the diseases in question may be extensively propagated by means of school children who are either infected themselves, or who come from families in which the disease prevails. This appears to be inevitable. But the question which should concern the health authorities refers to the possibility of reducing the number of new cases to a minimum. The present system of reporting cases to the board and then to the school, is for the most part too slow. Generally by the time such reports reach the teacher, the scholar who carries the contagion has already infected his classmates. Sanitary inspection of the children in school, and of the sick absentees, would settle the question at once; but we cannot mention such a project with any hope while the present school board exists. The next best thing is for the Health Board to educate the teachers as to their duties in the premises, to instruct them regarding the initiatory symptoms of the maladies in

question, so that the scholar who becomes ill shall be sent home at once. If such precautions could be taken, many might escape. Again, the teachers should be prevented from readmitting any scholar unless it is considered safe so to do by the family, dispensary, or hospital attendant. It is to be hoped, however, that the necessity for any unusual precautions will not show themselves.

THE STATE MEDICAL SOCIETY.

The approaching session of the New York State Medical Society, as is well known, will be the first one for several years that will be held in accordance with the laws that gave it a corporate existence. In the act of April 10, 1813, it was provided "that the Medical Society of the State of New York, and also the medical societies of the respective counties, shall and may agree upon and determine the times and places of their meeting; and the time so agreed upon shall forever thereafter be the anniversary day of holding their respective meetings."

In pursuance of this the State Society selected the first Tuesday of February as the day for their anniversary meeting, and the different county societies selected such other days as seemed most convenient. Subsequent legislation in 1818 and 1823 enabled the county societies to change the times for their annual meetings, but did not confer the same privilege on the State Society, which continued to hold its meetings at the appointed times, up to and including the year 1875. At the annual meeting in that year, held as is usual in February, a majority of the members seemed to think that a change to one of the summer months would be desirable, and the following resolution was adopted: "That a committee of three be appointed by the President to make application to the Legislature, now in session, for the purpose of changing the time of the annual meeting of the State Society from the first Tuesday of February to the third Tuesday in June.

After the transaction of other business the Society adjourned *sine die*. It does not appear from the published transactions that the committee referred to were appointed; at all events no change as to the time of meeting was authorized by the Legislature. In the following year, however, an act passed February, 1876, permitted the State Society to change from time to time the day of holding its annual meeting, "by a two-thirds vote of all the members present at any anniversary or annual meeting of said Society, provided that no such change shall be made unless notice of the intention to change the time of such annual meeting shall have been first given at a previous regular annual meeting. An entry on the minutes of said Society of notice of such intention to change the time of the annual meeting, and an entry on such minutes of the vote taken upon any motion made pursuant to

any such notice, shall be *prima facie* evidence of such notice, motion, and the vote had thereon respectively."

The Transactions of 1876 open with the statement that "The society met pursuant to statute in the Assembly Chamber of the Capitol, at Albany, at eleven o'clock A.M., June 20, 1876." Pursuant to statute in this connection is rather peculiar, as it certainly was not pursuant to the statute of 1813, nor the one of 1876, which requires, first, notice of intention to change, and second, a two-thirds vote in favor of change at a subsequent anniversary meeting. Neither of these requirements appear to have been fulfilled, for the resolution passed in February, 1875, appointing a committee to make application to the Legislature cannot properly be regarded as a requisite "notice," for the simple reason that the State Society did not then possess the legal power to give such notice.

The proper time, therefore, for the annual meeting of 1876, was February; but it does not appear from the Transactions that any meeting was held at that time. It is rumored, however, that a number of gentlemen gathered themselves together in the name of the State Society at the time at which it should have met, and there and then voted to hold the annual meeting in June. If such is the case, why have the minutes of this meeting been concealed or omitted from the Transactions? We are forced to the conclusion, therefore, that the June meeting in 1876 was *not* held pursuant to statute. The annual meeting of 1877 was also held in June, and at this meeting it was ordered, without any regard to the statute of February, 1876, that the next annual meeting be held in January, 1878. At this latter meeting it was clearly evident to the managers of the State Society that the meeting was illegal, and in order to rehabilitate the society, it was determined to transact the usual business, and to have it confirmed by a quorum which should meet in June following. As the previous June meetings were probably contrary to statute, so was this one; nevertheless, it confirmed the proceedings of the January meeting, and ordered that the next annual meeting be held on the first Tuesday of February, as was formerly the case.

The facts above stated would be of little consequence or interest were it not that the Medical Society of the State of New York possesses very important powers conferred by law, which enable it to exert a decided influence regarding the material welfare of the profession in the State. In many respects its authority over the county societies, and even of their individual members, is supreme; and the presumption is, that this authority will only be exercised for the general good of the profession and the public. If these ends are to be attained, and the powers of the State Society to be preserved, it is clearly necessary that all of its proceedings should be in accordance with the laws to which it owes its existence. If not thus protected, any malcontent can raise in the courts the question of

its jurisdiction, and might in some events deprive it of its corporate rights. The ultimate responsibility for blunders of this sort naturally rests with the presiding officer, whose duty it is to be familiar with the laws pertaining to the duties of his office, and of the society over which he presides. We refer to the past as a warning for the future.

Reviews and Notices of Books.

ON REST AND PAIN. Lectures Delivered at the Royal College of Surgeons of England, By JOHN HILTON, F.R.S., F.R.C.S., etc., etc. Second Edition. Edited by W. H. A. JACOBSON, F.R.C.S., etc. Cloth, 8vo., pp. 299, with wood-cuts. New York: Wm. Wood & Co., 1878. Wood's Medical Library of Standard Medical Authors.

THIS is the first volume of the series of Wood's Medical Library of Standard Medical Authors, and aside from a notice of the work itself, invites a word or two of comment upon the plan of publication and what may probably be expected of it. It will be remembered that some time since, W. Wood & Co. announced their intention of reproducing in this country the works of standard medical authors abroad at the exceedingly low price of one dollar per volume. That they have done all that they have promised thus far cannot be questioned, as the work is well printed, contains nearly three hundred pages, and is substantially and handsomely bound. Except for the marked encouragement which has already been received, the placing of such a work upon the market at such a price would be simply impossible, if not ridiculous. As it is, the profession may congratulate itself that the scheme is successful, and that for a merely nominal sum the practitioner has within his reach twelve exceedingly valuable volumes by standard authors. We are assured that the greatest care will be exercised in the selection of the works, and if the present is an index of the works of the future, there need be no more fear of the character of the authors than there will be of the cheapness and satisfactory style of the publication. Hilton on Pain and Rest is a work which has such an established reputation, that it is unnecessary to give any extended notice of it.

PRESCRIPTION WRITING, designed for the use of medical students who have never studied Latin. By FRED. H. GERRISH, M.D. Pp. 51. Portland, 1878: Loring, Short & Harmon.

A MANUAL OF PRESCRIPTION WRITING. By MATTHEW D. MANN, A.M., M.D. Pp. 155. New York, 1878: G. P. Putnam's Sons.

THESE are both capital little books, each better than the other in certain respects. The first gives the usual rules for prescribing, and, in addition, a few easy lessons in Latin, including the declension of all the official names of the Pharmacopœia which the physician must know if he desires to write his prescriptions with accuracy. Besides these, there are many excellent practical hints of value to every one.

Dr. Mann's book gives the general rules for prescription writing, a little Latin, together with the principal words and phrases used in prescriptions, with their pronunciation and abbreviations. Following these is a complete list of all the official and many non-official drugs, with doses both Troy and

metric. The work concludes with chapters on the combination of drugs and on incompatibilities.

Our only regret is that both books were not written by the same author, or that in the future they cannot be bound together, as each is the complement of the other, and should be in the possession of every student and physician in the country.

THE ANTAGONISM OF THERAPEUTIC AGENTS, AND WHAT IT TEACHES. The essay awarded the Fothergillian Gold Medal of the London Medical Society for 1878. By J. MILNER FOTHERGILL, M.D., Edin., M.R.C.P.L., etc. Svo, pp. 157. Philadelphia: Henry Lea. 1878.

This is another of those practical, charmingly written and valuable books which the distinguished author has given to the profession. Although a small volume, it contains a rich mine of not only facts, but suggestions. It is another contribution to the scientific explanation of the action of medicines (toxic), which, till of late, have only been used empirically. The seeker after scientific facts, upon which to base a rational and more or less precise treatment, will find within the covers of this small, unpretending volume a very "fair bird's eye view of the subject of the antagonism of toxic agents, so far as this is possible at the present time." The author divides his subject into two parts: the experimental inquiry, and the practical inquiry. The agents considered are aconite, atropia, ammonia, calabar bean, caffeine, chloral, digitalis, morphia, picrotoxine, prussic acid, strychnia, and some others incidentally. In the first part, many of the experiments (condensed), and the conclusions of Preyer, Frazer, Edinburgh Committee of the British Medical Association (Professor J. Hughes Bennett, Chairman), MacKendrick, Critchton Browne, Haynes (Philadelphia), finally, the author himself, are presented. Wood, Bartholow, Harley, Ringer, Lauder Brunton, and others are also referred to, especially the first.

Hermann's view of the nervous system as "a liberating force," and the action of certain nerve-centres as the rhythmical discharges (Wundt) serves for the explanation of the action of drugs upon circulation, respiration, etc., making Chapter V. especially interesting and worthy of every medical man's careful perusal. We cannot go into details, the book must be read to thoroughly understand its practical bearings and suggestions. We may say, however, that herein is found a full *résumé* of the author's essay on "Digitalis: its Mode of Action, and its Uses," now out of print. We most heartily urge practitioners to avail themselves of the immense amount of truly scientific and practical knowledge which can be derived from the work under review.

TRANSACTIONS OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY, Vol. I., No. 1. Cambridge: Riverside Press, 1878.

The members of this society have every reason to be proud of their labors in the year gone by, labors towards perfecting an excellent system, and accomplishing the great end at which they aim. Every righteous man cannot but rejoice in the abolishment of the coroner system in the Bay State, and would gladly hail its demolition in every State in the Union, in every civilized country. The contents of the pamphlet before us are:

1. The law abolishing the office of coroner and providing for medical examinations and inquests in cases of death by violence.
2. Constitution and by-laws of the Massachusetts Medico-Legal Society.

3. Officers and members thereof.

4. An introductory address by the President, Alfred Hosmer, M.D., which points out the advantages to society which the new system of inquests and examinations will afford.

5. "The Relation which Chemistry Bears to Forensic Medicine," by Prof. E. S. Wood, M.D., is a short, though suggestive paper.

6. "The Value of Anatomical Appearances," by Prof. R. H. Fitz, M.D. As the author declares, "the object of the present paper is to refer very briefly to some of the general points to be borne in mind in making an autopsy, and to consider the group of changes found in a very common form of death—that from suffocation." This paper is a very valuable one.

7. "Concerning Coroners and the Theory and Practice of Inquests," by Theodore H. Tyndale, Esq., and

8. "The Work and Duties of the Medical Examiner," by F. W. Draper, M.D., two papers illustrating the new *versus* the old system.

9. "A Case of Arsenical Poisoning, with Fatty Degeneration of the Liver, Kidneys, and Gastric Glands," by J. G. Pinkham, M.D., a case of great interest, and remarks of considerable value.

10. Report of the Corresponding Secretary, including five full reports from medical examiners, which certainly should serve as models in recording inquests and examinations in cases of suspected violent death.

We cannot too forcibly urge our readers to peruse this little pamphlet, which so satisfactorily sets forth the immeasurable advantages of placing forensic medicine into the hands of specially educated and qualified medical men instead of coroners, as under the prevailing system.

PRACTICAL SURGERY: Including Surgical Dressings, Bandaging, Ligations, and Amputations. By J. EWING MEARS, M.D., Demonstrator of Surgery in Jeff. Med. Coll., etc., etc. 12mo, pp. 274, index, and 227 illustrations. Philadelphia: Lindsay & Blakiston. 1878.

This small volume contains a great deal of information upon the subjects of which it treats in a convenient and condensed form. Each division is well illustrated, thereby rendering the text doubly clear. Lister's "antiseptic dressings" are well described. The chapter on "Bandaging" is excellent; all the ordinary varieties, as well as Mayor's "handkerchief system," the starch, plaster-of-Paris, silica, and Sayre's suspension apparatus, are described and illustrated. "Ligations" are arranged under special heads for each artery, viz., Surgical Anatomy, Course, Surface Markings, General Relations, Guide, Structures to be Avoided, Operation. The illustrations of this subject are profuse and fairly good. "Amputations" is an equally good chapter. Especially useful are the representations of sections of the various extremities at different points, showing the structure.

TRANSACTIONS OF THE INDIANA STATE MEDICAL SOCIETY, 1878. Indianapolis: Indianapolis Journal Co., Printers.

The President, Dr. L. D. Waterman, delivered an address upon "State Preventive Medicine," in favor of placing the prevention of disease in the hands of specially educated men who shall be responsible to and presided over by the State. A long and interesting review of the legal conflict which lately occurred in Indiana, relative to the right of medical *experts* to demand and obtain a *special fee* for their testimony as *experts* before giving such testimony or services, comes from Wilson Hobbs, M.D., under the heading of "The

Medical Witness." So far, we are glad to be able to say, the Supreme Court of Indiana has sustained the doctor's claim.

Dr. J. H. Hibberd, "Infantile Convulsions: What should be the Treatment during the Paroxysm?" contends that nothing further than protecting the child from self-injury, and giving a supply of air, should be done. Six cases of "Conservative Surgery," by L. Humphreys, M.D., and the "Report of Public Hygiene in Indiana," by Thad. M. Stevens, M.D. (Chairman), present nothing new or of special interest. The special interest in Dr. T. Fravel's article, "An Epidemic of Diphtheria," is found in his treatment of the disease. He has no great faith in the therapeutics, believing that very little beyond good nursing and hygienic measures is required, the fatality not being due to improper or inadequate treatment, but to the inherent individual impotence to throw off the impressions of the disease. The medicines used were: R. Potassæ permang., gr. iv.; Aquæ font., f. ʒ iv., M. Sig. Teaspoonful every two hours, day and night, alternated with a teaspoonful of the following: R. Ext. belladon. fl., gtt. viij.; Aquæ font., f. ʒ iv. The following gargle was used each hour between the above doses: R. Potassæ chlorat., ʒ ij.; Sodæ hypsulphit., ʒ ij.; Sodii chlorid., ʒ i.; Tr. capsici, f. ʒ (or alcohol, f. ʒ ij.); Aquæ font., f. ʒ vi. M. The throat was cleansed with warm water each time before using the gargle, and nothing taken into the mouth sooner than ten minutes afterward. "Topically I applied once in twenty-four hours equal parts of a strong solution of tannic acid and tinc. mur. iron. When the Schneiderian membrane was involved, I passed through the nostrils, once in three hours, by means of a nasal douche, from four to five ounces of a solution of permanganate potassa in very warm water, three grains to the pint. Milk and animal broths were freely given throughout the disease. In cases of very young children, eighteen months old and under, nothing but the potassæ and belladonna were used, and recovery followed as speedily as with the gargle and local treatment." The above formulæ are of the right proportions for children; for adults they might be increased. John S. Dare, M.D., claims that "nasal catarrh" is, in its chronic stage, *infectious*; not always, but in many cases.

Thos. J. Dills, M.D., reports a case of "Graves' Disease," in which he found large doses of digitalis especially useful. "On the Ætiology and Treatment of Unavoidable Hæmorrhage," and "Placenta Prævia," by G. W. Mears, M.D., and George Sutton, M.D., respectively, are two papers of practical interest. In the former the tampon, till the full dilatation of the os (the *membranes remaining unruptured*), with subsequent natural or instrumental delivery, is strenuously advocated as the best treatment. The best tampon is a sponge saturated with persulphate, perchloride, or pernitrate of iron, with charpie packing beneath, all applied through a speculum, says the author. This treatment is only applicable to the *unavoidable* variety, namely, that occurring *during* labor, and due to a separation of the placenta consequent upon dilatation of the cervix and os, and *when the membranes remain unruptured*. Dr. Sutton, however, would prefer to rely upon *forcible digital* (or by the aid of water-bags) *dilatation*, and, in certain cases, even *free incisions of the cervix*, followed by podalic version.

Two short papers, "An Epidemic of Small-Pox," by W. W. Blair, M.D., and "Upward Dislocation of the Sternal End of the Clavicle," by Joseph Eastman, M.D., the minutes of the transactions, and a list of members, close this interesting volume.

HORSEBACK RIDING FROM A MEDICAL POINT OF VIEW. By GUISLANDI DURANT, M.D., Ph.D., etc. Royal 12mo, pp. 137. New York: Cassell, Petter & Galpin. 1878.

THE first thing which astonishes the reader is how the author of this work could extend such a subject as this over 137 pages; but it is soon evident that the title is only partly appropriate, good as far as it goes, since metaphysics, history, physics, physiology, etc., are all thrown into the first chapter comprising only fifteen pages. The effects of exercise, the minutest details of the mechanism of horseback riding, the physiological effects of the same exercise on the animal economy, special and general, its therapeutical and hygienic effects, and, finally, "the origin and progress of horse-racing," are all treated of in so many distinct chapters. Dr. Durant undoubtedly believes horseback riding to be a most wonderful and potent remedy, when he says that syphilis "can be benefited by horseback riding. Nothing is more true, however." Altogether the work, although readable and interesting, is apparently written as much to give the author's views upon a wide range of medical subjects as for any other purpose. From a practical point of view the work has no special value.

NINTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS. January, 1878. Boston: Ræd, Avery & Co., Printers to the Commonwealth. 1878.

LIKE its predecessors, this report is a model of excellence, industry, and practical worth. Among the excellent papers in this volume, we would call attention first to that on "Drainage and Health; Sewerage and Pollution of Streams, including a Draft of a Law." "Cottage Hospitals" is the title of an interesting paper by Dr. J. F. A. Adams, of Pittsfield. All who are interested in "Dangers from Color-Blindness" will find Dr. B. Joy Jeffries' (of Boston) paper interesting. He adds *seven* pages of bibliography to the paper proper. The importance of the "Filtration of Potable Water" receives due attention from Prof. Wm. Ripley Nichols, M.D. "Sanitation of Public Schools in Massachusetts," by D. F. Lincoln, M.D., should be carefully perused. A highly valuable article on "Scarlet Fever" is from the pen of A. H. Johnson, M.D. The description and drawings of the (disinfecting establishment (hot-air) in operation in Liverpool, England, makes this paper doubly valuable.

The relation of drainage to diphtheria, typhoid fever, etc., closes this valuable contribution to State medicine.

THE PATHOLOGICAL ANATOMY OF THE EAR. By Prof. HERMANN SCHWARTZE, M.D. Translated by J. ORNE GREEN, M.D. Boston: Houghton, Osgood & Co.

THIS small book of 174 pages is, as the translator states in his preface, "the only comprehensive work strictly devoted to the pathological anatomy of this organ" (the ear). It is a carefully prepared catalogue of all the pathological changes that are known to have taken place in the ear. In many portions it is more than this; the actual pathology of the disease is described, its relative frequency is stated, and full references are given to the sources from which the information has been gathered.

The beginner will perhaps find the book a little dry, but to those who have occasion to treat diseases of the ear it will prove a most useful work of reference, enabling them to interpret rightly the different pathological states which from time to time come

under observation. Individual theories occupy a minimum of space in the book, while the firmly established pathological facts are set forth in clear and simple language. The translation has been well done. Numerous woodcuts aid in elucidating the text, and the typographical work is excellent.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA. Vol VII. Edited by J. HENRY C. SIMES, M.D. Philadelphia: J. B. Lippincott & Co. 1878.

This handsomely-bound and printed volume is a valuable contribution to pathology. The subject-matter is arranged under appropriate headings, such a classification materially adding to the convenience of reference. Each report is as concise as a proper presentation of the case or specimen would allow. The work opens with some interesting reports of lesions of the osseous system. Especially worthy of notice is Art. 8: "Intracapsular Fracture of the Femur—Thrombosis of the Left Femoral Vein Extending to the Vena Cava," by Dr. J. C. Wilson. Quite a number of cases of cancer of the digestive organs are recorded. "Case of Mitral, Tricuspid, and Aortic Disease, with Pulsation of the Liver, and Pericardial Adhesions," by Dr. John Guitrás, is of special interest *per se*, and on account of the remarks made upon the case. Dr. James H. Hutchinson gives an account of a very interesting case of "Interstitial Nephritis, in which there were Marked Retinal Changes, Pericarditis, and Pericardial Effusion." We must call special attention to "Specimens Illustrating a Case of Extra-Uterine Pregnancy," by Dr. Frederiek P. Henry, which is illustrated by two very fair drawings by Dr. C. B. Nanerode. This was of the abdominal form of ectopic gestation. Dr. E. O. Shakespeare gives quite a long account of the histological appearances of the specimens.

Another case and specimen of abdominal pregnancy is here presented by Dr. Wm. Pepper, also illustrated by two woodcuts from the same draughtsman. Both these cases are of considerable importance and practical interest.

A case of "Elephantiasis of the Penis" is reported by Dr. F. Duffly, of Newbern, N. C. Some very practical remarks are made by Dr. Harrison Allen upon "The Anatomy of the Cerebrum."

A case of "Cerebral Abscess and Dilated Bronchi," by Dr. J. H. Hutchinson, will bear careful study on the part of our readers. The history and autopsy are detailed at length, the diagnosis was particularly shrouded in obscurity, and the remarks of Drs. Pepper and Allen are of interest.

Dr. Morris Longstreth calls attention to the advantages of Prof. Wm. Rutherford's freezing microtome.

An excellent article by Dr. Charles B. Nanerode, on the pathology of malignant morbid growth, concludes this interesting work. We have only mentioned the few more important papers (as they seem to us) of this volume, and have given but a faint idea of its value. We recommend all those interested in the subject of pathology to add this handsome book to their collection.

PILL-COATING.—The process of pill-coating of M. Raquin (reported to the Academy in 1837), namely, by a layer of *gluten*, is said to be superior to that by gelatine, since the pills or capsules pass by the saliva and gastric juice unaltered, to be acted upon by the intestinal juices, through absorption taking place. Such remedies as oils of copaiva, turpentine, etc., are not, therefore, eructated.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 19, 1878.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

THE OPERATION FOR LACERATION OF THE CERVIX UTERI, OR THE INDICATION FOR HYSTERO-TRACHELORRHAPHY.

DR. PAUL F. MUNDÉ read an interesting paper upon the above subject, of which the following is a brief abstract:

Reference was first made to the history of the operation. Papers descriptive of the lesion and its operative cure had been written by Emmet, Pallen, Wing, Baker, Breisky, Dudley, and others, and upon careful perusal of them, with their accompanying diagrams, Dr. Mundé was confirmed in the impression that all those authors had written only of *complete* laceration or fissure of the cervix, either unilateral or bilateral, with a rolling out of the lips of the cervix up to the vaginal reflection; the cervix presenting the appearance of an eroded surface two inches or more in diameter.

Those were the typical cases of the lesion, and no experienced and unprejudiced observer could, at the present day, entertain a particle of doubt regarding the efficacy of Dr. Emmet's operation and method of treatment. But so uniform as was the acceptance, by all the initiated, of Emmet's operation for those graver forms of the lesion, even so greatly divided did the profession still seem to stand with reference to the exact point when a laceration and erosion of the cervix required operation, and when it was still curable by topical applications, such as astringents, caustics, or cautery. The uncertainty was not confined to *medical* gynecologists proper, but even some of the leading uterine surgeons had expressed the opinion that the minor degrees of laceration and erosion did not require operation, as they were too insignificant to be productive of evil, or could be cured by mild astringents. On this point Dr. Mundé referred to the protest which Dr. Chadwick, of Boston, had made against the impression unintentionally conveyed by Dr. Wing, that these lesions were curable only by operation.

Further reference was made to views entertained by Drs. Barker and Jacobi, of New York, as published in the *MEDICAL RECORD*. (See pp. 193-196, Vol. XIII, 1878.)

In Europe, with but few exceptions, the existence of laceration or fissure of the cervix as a distinct lesion, requiring recognition and treatment, appeared scarcely to have dawned upon the profession. With almost wilful neglect, it would seem all mention of the affection was omitted in the two latest books on gynecology, Barnes and Leblond. While the author of the paper admitted that slight laceration or nick of the cervix, without ectropium, and with normal mucous surfaces—or even deep fissures without eversion—or deep lacerations with eversion, but with the whole everted cervical mucosa cicatrized and smooth, in no wise called for operation or other interference (except there was cervical neuralgia from inclusion of nerve-filaments in the cicatrix), yet his experience decidedly warranted him in claiming that there were numerous cases of minor degrees of cervical laceration and eversion in which the plastic operation was

the most safe, sure, and rapid therapeutic measure for the relief of the local disease. The cases were classified as follows:

1. Slight lacerations, which ordinarily gave no trouble whatever, but in which, under the influence of friction against the posterior vaginal wall (the uterus often being subinvolved and depressed), the trivial ectropium became a profusely secreting ulcer, gradually spreading into the cervical canal, and producing the familiar mucopurulent tenacious plug projecting from the fissured os.

2. Slight lacerations, perhaps not ulcerated, and non-productive in themselves of local disturbance, but still acting through the gaping and everted os, as chronic feeders of the subinvolution and hyperplasia, against which we all acknowledged our boasted therapeutics, local and constitutional, to be ordinarily of little avail.

3. Cases of hyperplastic or cystic ectropium of one lip in which a raw, ulcerated surface, often one-half to one inch in diameter, took the place of the lip. To excise that redundant and useless piece of tissue, slightly pare the edges of the broad cervix, and restore the normal transverse os, was certainly a much neater way of curing the difficulty than by the tedious cautery.

4. Cases of laceration of the endocervical mucous membrane, with comparatively slight injury to the border of the os, which, however, was patulous and funnel-shaped, often admitting the point of the index finger, and frequently everted and eroded (Barnes, Fig. 117). The gaping os was usually filled with a mucopurulent, tenacious plug, the result of endocervicitis from exposure, and the patient complained of the symptoms peculiar to that condition. There also the strong caustics failed, or were tedious.

5. We were all familiar with the difficulty experienced in curing large granular and follicular erosions of the cervix by caustics. Why not, then, hasten the cure by removing the diseased mucous membrane, and uniting the healthy edges by sutures, as was done in Emmet's operation? He was confident much time could thus be saved.

Dr. Mundé did not deny the statement that the majority of *fresh* cervical lacerations would get well merely with cleanliness and the recumbent posture, nor that many cases could be cured by the treatment advocated by Drs. Barker and Jacobi; but he would ask, What was the advantage of subjecting patients to a treatment extending over weeks and months, and confinement to a recumbent posture for two or three weeks, enlivening the monotony of that course by the occasional application of the actual cautery, when all that could be obtained (the wound closed, the cervix restored to its normal shape, and the uterus certainly diminished *somewhat* in size) after less than two weeks' confinement in bed by an almost entirely safe, simple, and comparatively painless operation?

That the operation was comparatively devoid of danger had been shown by the statistics of the New York Woman's Hospital. That the operation occasionally failed was true, but failure was chiefly due to the lack of preparatory treatment, to insufficient paring and careless adaptation of the wounded surfaces, and to influences not under the control of the surgeon. A second operation usually cured the case.

During the past year he had twice performed the operation for lacerations, in both of which cases the indication was not the *extent* of the injury, but the irritation exerted on the hyperplastic uterus by the friction of the everted surfaces, and the beneficial influence to be expected for the reduction of the en-

largement. Those indications were confirmed by Dr. Thomas, who saw the ladies with him in consultation.

After giving the history of the two cases mentioned, Dr. Mundé stated that the object of his paper was to demonstrate, not that *every* laceration of the cervix should be operated upon as a duty, for he believed that a certain proportion of those lesions either did not require any treatment, because they produced no symptoms, or, in a lesser proportion, were amenable to caustic and astringent applications—but that there was a very large class of cases in which the operation was called for, not by the extent of the injury, but by the symptoms which it produced and the pathological conditions which it aggravated or maintained. Those cases have been stated above.

He further thought that we should soon be able to operate on those slighter cases of laceration and eversion at our offices or at the Dispensary, send them home by the cars, and let them go about their ordinary avocations (avoiding unusual exposure, of course), to return for the removal of the stitches at the end of a week. The absence of etherization, and the use of silk instead of wire, materially simplified and shortened the operation. When it had once been demonstrated that that plan was followed by success as regarded union, then the great objection to the operation among the poorer classes—the confinement to bed—would be removed, and old cases of cervical ectropium should disappear from our clinics. Still, he considered the recumbent position during convalescence as a most important factor for the ultimate results of the operation, and one always to be insisted upon when feasible.

In conclusion, Dr. Mundé referred to the experience upon which his remarks and conclusions were based. The percentage of lacerations observed by him at the out-door department of the Mt. Sinai Hospital during the last two years was 17 per cent., and served to illustrate very aptly a remark made by Dr. Barker, on the occasion above mentioned, "that the lesion occurred with vastly greater frequency in persons who had had neither skilled obstetrical attendants nor the care and rest required after confinement, since in his own practice, confined to the more wealthy classes, he had met with this accident in but two well-marked cases."

That the high percentage was not accidental or confined to the class of patients which appeared at the hospital, was confirmed by the experience of Dr. Goodell, of Philadelphia, who inferred that about one out of every six women suffering from uterine trouble had an ununited laceration of the cervix.

The paper was illustrated by colored plates of the various forms and degrees of laceration and ectropium of the cervix uteri, prepared from nature by Dr. A. H. Friedenbergh, House-Physician to Mt. Sinai Hospital.

The paper being before the Academy for discussion,

DR. T. A. EMMET remarked, with reference to the frequency with which the lesion occurred, that, as well as he could recollect, in about 34 or 35 per cent. of all the cases of uterine trouble he had seen since 1862, he had recognized laceration of the cervix. He was disposed to take exception to the statement that the lesion was found most commonly among the poor, for in his private practice, which he supposed was among as good a class of people as the average practitioner obtained in his department, he had seen the lesion more frequently than in the Woman's Hospital, if those cases were included in which delivery was made by instruments.

There were only certain conditions of laceration of the cervix which called for operative interference, for he supposed that the cervix uteri of every woman,

with the birth of her first child at least, was more or less lacerated during parturition. If the laceration took place from before backward, or deviating from that somewhat, it usually healed before a month was passed, and gave no trouble.

It was only when the laceration was lateral, so that involution was arrested and the uterus laid upon the floor of the pelvis, the posterior flap getting into the cul-de-sac and the anterior sliding forward into the axis of the vagina, thus producing gaping and keeping up hypertrophy, that the operation was required. In such cases there probably was no relief, except by operation, or filling the gape with cicatricial tissue by the work of nature.

Dr. Emmet wished to lay special stress upon that point. At the time he wrote his last paper he supposed the eversion was the chief cause of the difficulty; but he now regarded it as the least. There were conditions in which the flaps gaped like the separation of two fingers, and nature would attempt to fill that gape with granulations. She might so succeed that only a slight rolling out of the tissues of the cervix could be seen, a condition which had been regarded as too slight to require interference. But those were the cases which required the operation even more than those in which eversion was a prominent symptom, and for the following reason.

When the gape was partially filled with cicatricial tissue, the circulation was obstructed and would remain so until such tissue was removed. If, therefore, the edges were denuded and brought together over the cicatricial plug, even though union might occur, cure would not be effected, and the woman would remain an invalid. In fact, the uterus would increase in size, or absorption take place, and the operation fail.

With regard to the cicatricial tissue, when it nearly filled the gape, most operators would say that an operation was uncalled for, recognizing the necessity for an operation simply by the fact that the edges of the fissure were rolled out, and not recognizing the necessity of removing that plug. The cervix was poor in blood vessels and nerves, but it was covered with erectile tissue in which were found fibres of the sympathetic system, and the sympathetic nerves presided over nutrition as well as over the organs of generation during the menstrual period, say from the age of fifteen to forty-five.

Dr. Emmet held that the cicatricial tissue there was a source of irritation, apart from the gaping, and apart from its effect upon nutrition, and consequently it gave rise to excessive anemia, which continued until the woman ceased to menstruate. The anemia was persistent, and at the change of life nature went to work, to set the house in order as it were, and absorbed all that cicatricial tissue, and put the uterus in a condition in which it might rest quiescent for the remainder of life.

Very often nature was not competent to bring about absorption of the cicatricial tissue, and then followed a development of epithelioma. Dr. Emmet felt satisfied that such result obtained, although he was not able to prove his position. He believed that epithelioma of the cervix uteri always arose from an unsuccessful effort on the part of nature to remove such cicatricial tissue. He took that view from the fact that of eighty or ninety cases of malignant disease of the cervix which he had collected, there was only one occurring in a woman who had not been impregnated, and he had not seen any one who could say that he had seen such a case.

The histories, almost without exception, dated back to some labor of unusual severity and delivery by in-

struments, and the natural inference was, that in such cases laceration of the cervix had occurred. In some of the cases laceration had been recognized years before they came under Dr. Emmet's observation; in most instances, however, it was not recognized.

Dr. Emmet further remarked, he had always held that the operation was the last resort, and not that every case should be operated upon. The operation was simply for the purpose of keeping what was obtained by other treatment. The woman should be put into the best possible condition, and then in extreme cases, if the operation was performed, the woman was cured permanently.

Dr. CHAMBERLAIN expressed his concurrence with the statement of the paper that, even if the visible lesions of eversion, hyperplasia, cystic degeneration, etc., were in many cases curable without the operation; yet if they were more quickly, certainly, and completely cured by the operation, as he believed they often were, then the operation was expedient and to be advised. In the minor cases of comparatively recent laceration, it was so easy and so little painful or dangerous, that there was no valid argument against it. It was not an operation of mutilation, but of repair.

Like Dr. Mundé, he had twice done it without the aid of an anæsthetic.

It was constantly done so as to be free from any constitutional reaction. There were one or two points in the technique to which he alluded, and although they might not be original with him, yet he had not seen them mentioned in print or known of their employment by others.

The greatest difficulty which he had experienced was in making sufficiently thorough excision of the angle at the bottom of the fissures. When all the tissues were oozing, it was difficult to be certain that there was not left some band or island of mucous surface undenuded.

That difficulty was greater in proportion as we operate high up in the vagina, and less in proportion as the cervix was brought down near the outlet.

In order to obtain full control of the uterus, he had, in bilateral laceration, sometimes passed a wire deeply through the cervix on either side, leaving between the two an interval corresponding to his idea of the proper size of the cervical cavity. Those wires were made to pass so deep as not to emerge in the fissure, but could be uncovered by a slight incision of the floor of the fissure. When so found, the wire was caught with a tenaculum, and a long loop pulled up from the bottom of the fissure. Those loops were then cut, and thus we had a loop in the anterior and another in the posterior lip on either side of the cervical canal. Thus the cervix might be easily drawn down to the vulva, the speculum become unnecessary, and every portion of the fissure, successively, might be made to present and kept perfectly steady until it was denuded. When that was done, the wires were joined where they had been cut, the loop was drawn straight, and thus the two first and most important stitches were placed just where they should be. As many more as were needed were then easily passed on either side.

He also mentioned an observation on the physiology of the changes which occurred in these cases. He had very constantly noted that, if the curve of the lines of fissure was upward, then the eversion and the hyperplasia was of the anterior lip; if downward, of the posterior. That meant, he thought, that the derangements of nutrition affected that portion of the cervix in which the circulation had been most impaired.

DR. GILLETTE thought it important to consider how these lacerations could be prevented, and believed that we had reached a period in the study of the injury which permitted us with propriety to consider that question. Undoubtedly laceration of the cervix in the parous woman was a physiological condition up to the degree which was short of eversion of the cervix, or of that hyperplastic condition described by Dr. Emmet.

The operation had become so popular, and was so easily performed, that in his experience it was being done in cases in which there was no real necessity for it. It was the habit of some physicians to sew up every lacerated cervix which could be discovered, without regard to pathological phenomena associated with it. He thought that a warning voice should be lifted and a line of distinction be drawn as to when the operation should be performed, and in that respect the author of the paper had made a valuable suggestion.

In some instances he had known of the operation being done immediately after delivery, and practically he was not able to see why it should not be done at once. We did not hesitate to close a lacerated perineum at once, and why we did not do the same with a lacerated cervix was probably because we did not take the time or were afraid of the consequences. Whether it was an advisable operation or not, at that time, he was not willing to say from his own observation or from what he had heard, but he thought it was worthy of trial. It had occurred to him that if the plastic operation could not be performed, perhaps some instrument could be devised which would hold the lacerated surfaces in contact. According to the suggestion made by Dr. Emmet, and subsequently by Dr. Skene, he had used what was known as the preparatory stitch in cases in which rapid absorption of the hyperplastic tissue could not be obtained; but in instances in which there was considerable eversion and hypertrophy, the stitch was apt to tear out.

Recently he had resorted to a rather novel method of treatment, which consisted in seizing the torn cervix with two tenacula, drawing the lacerated surfaces together, and then slipping over the handles and around the cervix an ordinary rubber strap. One week afterwards he found that the compression made by the band had acted in a very favorable manner. From his experience in that case it had occurred to him that, perhaps, a bandage which could be used in recent lacerations might be constructed. At all events, he felt inclined to determine whether it was safe to try to cure these lacerations during the puerperal period.

DR. H. T. HANKS remarked that he had been specially interested in the statistics given by Dr. Mundé, for he had found by consulting the books in his department at the Demilt Dispensary, that the percentage of cases of laceration of the cervix was less than it was when he gave it at the time Dr. Emmet read his second paper. Of 881 women treated in that institution for diseases peculiar to the sex, only about six per cent. suffered from laceration of the cervix. When he made his former report, the percentage was between eight and nine per cent. The subsequent reduced percentage he ascribed to the fact that young physicians had kept their patients in bed after confinement, and taken better care of them than formerly. In that particular the teaching had been more careful than formerly. Consequently, the lesion had partially or wholly cured itself before the woman assumed a position which favored its continuation.

Dr. Hanks also thought that the remarks made by

Drs. Barker and Jacobi, and already alluded to, had had an excellent effect, although at the time he was opposed to some of their conclusions. For he was certain that he had operated in some cases in which the patient was not placed in a proper condition by preparatory treatment, notwithstanding Dr. Emmet had justly called attention to that special point. The doctor also thought that we should know, as suggested by Dr. Gillette, if there was not some way to prevent the occurrence of the laceration. In this connection he believed that when the young men were taught to interfere less with the cervix during labor, we should have a less number of lacerations. If that was a fact, we should understand it, and bring it into daily application.

Again, in cases in which it was known that laceration of the cervix was present, it was well, after the fifth, sixth, or seventh day, to insist that the woman should lie prone instead of retaining the dorsal decubitus. For, by so doing, the lacerated cervix would be prevented from brushing the floor of the vagina, and thus the tendency to eversion could be prevented.

DR. GILLETTE remarked that he did not think management of the first stage of labor could be regarded as a factor in the diminution of the percentage of cases of laceration of the cervix. For the lesion was much more frequent a few years ago than now, but the usual teaching then was to do nothing in the first stage of labor. As he understood the subject it was the teaching of the present time to hasten labor by proper manipulation for the purpose of facilitating dilatation of the cervix.

DR. EMMET'S views upon the question were asked for, and he replied that he was unable to answer the question from any personal experience. He was satisfied, however, that with proper care a great many of these cases could be prevented from coming to a surgeon for an operation. For if the precaution was taken to wash out the uterine cavity after any difficult labor, and to use hot water freely so as to cause the uterus to contract more than it would naturally do in those cases, the result, doubtless, would be that in a large proportion the laceration would heal which otherwise would make the woman an invalid for years.

Without personal experience regarding the effect of hot water upon a lacerated cervix, he reasoned thus, by knowing what effect could be produced upon diseased tissue by that agent.

Reference was made to cases of vesico-vaginal fistula of large size which had closed without any treatment save cleanliness secured by vaginal injection of hot water, and he believed that if such precaution was taken after labor the number of cases of laceration of the cervix, and other conditions, would be very much diminished.

In closing the discussion,

DR. MUNDÉ remarked, that it was not his object in his paper to consider questions which had already been thoroughly discussed with reference either to pathology or to treatment. His object was simply to bring out certain indications which had not yet been presented for discussion.

He regarded the suggestion made by Dr. Chamberlain as an excellent one, and was quite sure that he had seen Dr. Thomas manipulate in very much the same manner, except that he took only one lip. Dr. Goodell, of Philadelphia, had also spoken of the same manipulation.

With reference to Dr. Gillette's suggestion concerning the use of a rubber band, he thought it would be an excellent aid in the treatment of old lacerations, but he was not able to understand how it could be

employed immediately after confinement; for, if applied loosely, it would slip off from the cervix, and if applied tightly it would interfere with free discharge of the lochia. He also thought that an operation immediately after confinement would not be practicable, except, perhaps, in hospital practice.

The Academy then adjourned.

Correspondence.

THE PUBLIC HEALTH ASSOCIATION AND YELLOW FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

STR:—The influence which the recent meeting of the American Public Health Association is to have upon the future history of yellow fever, and upon medical opinion concerning the etiology of the disease, cannot at present be predicted, but it is to be hoped that the large and well-selected committee appointed may prove to be, as they ought to be, a controlling power so far as national legislation is concerned. That national legislation is urgently demanded, both by public sentiment and by the lamentable experience gained in the past at the expense of thousands of lives and millions of money, is, I think, the firm conviction of a large majority of those who were present at the Richmond meeting of the Association.

Dr. Choppin, the distinguished President of the Board of Health of Louisiana, who, from his experience and official position, speaks with an authority second to that of no other man in the United States, has the courage to use the following language in his report upon the recent epidemic in New Orleans:

"We in Louisiana, operating under a quarantine law not absolute in its restrictions, after an earnest effort in executing it, conducted with all the honesty and energy at our command, assisted by incorruptible quarantine officials, have utterly failed in preventing the importation of the pestilence which has thrown gloom and sorrow over our whole Southwestern Valley. No *conditional* quarantine can ever be made effective, because, first, of the laxity with which laws are unfortunately executed in this country; and secondly, because of the cupidity of commercial interests at stake, which will always move heaven and earth to evade successfully all quarantine laws and regulations."

I think I may safely say that a large majority of the members and delegates present agreed upon this practical point, viz.: that yellow fever in the United States *usually* results from the importation of *cases* or *fomites*, and that such importation can be prevented by *proper* quarantine restrictions. I think it is even safe to say that a majority were of the opinion that yellow fever *never* originates in the United States; but no vote having been taken upon the proposition, formulated by a committee, which embodies this view, I cannot be sure that I am right. The objection made to submitting this question to a vote was that the Yellow-Fever Commission had not yet completed its labors, and it was suggested that the discussion of the question be postponed for one year. This would have been a very proper suggestion if yellow fever had appeared in the United States for the first time in 1878; but the epidemic of 1878 is, unfortunately, only one of many, and counts no more in settling this question than an outbreak of which the victims can be counted on the fingers. The literature

of yellow fever is rather extensive, and many of those present at Richmond had witnessed numerous epidemics. We had listened to Dr. Choppin's able paper giving a clear account of importation to New Orleans in May of the present year; could we not, then, have been allowed to express our opinions in regard to this matter? Never in the history of the country has there been an assemblage of men so well qualified to give an opinion upon this subject; but they were not to give expression to their opinions because the Yellow-Fever Commission had not completed its labors.

I regret very much that the late hour at which this proposition came up for discussion made it necessary to accept a compromise amendment, which restricted the expression of opinion to a belief in importation, for the present year. I regret it chiefly because it gives color to the prevalent popular belief that the doctors know little or nothing about yellow fever, and that the late epidemic has upset all preconceived theories and opinions, and left us all afloat. Now, I claim that the etiology of yellow fever is as well settled as is that of typhoid or remittent fever, and that those in and out of the profession who are still in doubt as to how epidemics of yellow fever originate and progress may obtain reliable information upon the subject by consulting such standard medical works as Flint's Practice, Ziemssen's Cyclopaedia, and Reynolds's System of Medicine. All of these works give about the same account of this matter—an account which agrees with the facts and with the opinions of the best informed physicians in latitudes where the disease frequently prevails. Prof. Flint sums up our knowledge of the etiology of yellow fever as follows:

"To sum up the most important points relating to the causation, an unknown special cause—a poisonous miasm—is involved; the doctrine that this special cause is reproduced within the body does not rest upon adequate proof; the special cause demands for its development or efficiency conditions peculiar to certain localities, and a high temperature is an essential condition. Auxiliary causes which exist, especially in cities or large towns, exert a powerful agency in the production and perpetuation of the disease, and by the removal of auxiliary causes, epidemics may be prevented or divested of much of their fatality. Finally, the special cause may be transported by means of infected vessels, or fomites, and, in conjunction with a high temperature and auxiliary causes, the disease may prevail in places where it is not indigenous."

This is, I think, as clear and definite a statement as can be made concerning the etiology of the more familiar diseases above mentioned. I heard nothing at Richmond which will, in my opinion, make it necessary for Prof. Flint to make any change in the wording of this summary, and, so far as I can learn, the epidemic of 1878 does not materially differ, except in extent, from those which have preceded it.

In a recent number of the London *Lancet* (October, 1878), Dr. Robert Lawson, Inspector-General of Hospitals in the British army, makes the following sensible remarks:

"It is worthy of observation that the great majority of the members of the profession who have resided some years in the tropics, and had constant experience of yellow fever, entertain the first opinion (that it arises from local causes, and not from personal contagion), and it is only among those who have met the disease occasionally, or who have never been brought in contact with it, that the second is generally re-

ceived (personal contagion). It is not creditable to the medical profession that this question remains so undefined"

In the same paper Dr. Lawson gives the following instructive account of an outbreak of the disease on the ship *Isis* at Sierra Leone: "In 1865 yellow fever prevailed at Sierra Leone, and the *Isis*, receiving ship, which had been there some years, had several cases on board, of which the last two were attacked on the 16th and 18th of December, respectively, and both died on the 21st. A few days after, H. M. S. *Bristol*, with a crew of 535, arrived from England, and instead of running up to Freetown as usual, anchored in the open sea five miles from that place. It having been considered that the position of the *Isis* was unhealthy, a party of four officers and 112 men were sent from the *Bristol* on the 28th and 29th of December, to remove her to a healthier one. The party returned to the *Bristol* each night without going on shore. Fever commenced among the men of this party on the 31st December, and, up to January 6th, thirty-seven were attacked, and there was another on January 12th, the last which occurred. Of these 21 died on board from January 3d to January 10th, and two subsequently at Ascension. Twenty-nine cases were classed as yellow fever and nine as remittent. In the former the urine was highly albuminous in every case in which it was examined, loaded with tube-casts, epithelium, and blood cells, and black vomit was frequent, which conditions, as well as the rapid course of the disease and its enormous mortality, stamped it as malignant yellow fever. Two officers and one man of the *Bristol*, not of the working party, also went on board the *Isis*, and subsequently had fever. *All the attacks occurred in the Bristol, but no one suffered who had not been on board the Isis.* The best measures the circumstances permitted were taken to limit the exposure of the healthy among the *Bristol's* crew to the emanations from the sick, but five medical officers, and twenty-four men employed as nurses, were in constant and close communication with them, and fully exposed to whatever chances of contracting the disease these circumstances might involve."

This is but one of thousands of examples which prove clearly that yellow fever is contracted, not from the sick, but by exposure to an infected locality.

The facts observed and recorded by myself for four minor epidemics fully support this statement, and the matter is so thoroughly settled that in future investigations, it seems to me, we should turn our attention to the discovery of the unknown special cause and to careful estimates of the comparative value of the auxiliary causes, with reference to the exclusion of the former, and, so far as practicable, the removal of the latter.

GEO. M. STERNBERG,
Surgeon, U.S.A.

FORT WALLA WALLA, W. T., Dec. 18, 1878.

CYSTITIS AND THE USE OF ACIDULATED WATER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Noticing in your issue of December 28th a communication from the hands of Dr. W. H. Bramblett, of Newbern, Va., on the treatment of "atony," and "dilatation of the bladder," "cystitis," etc., with cure of two cases from the use of "acidulated water," made by the addition of cider vinegar to a quantity of cold spring water of "about 75° to 80° F.," etc. The writer seems to find fault with Dr. Van Buren,

while he apparently lays himself open to a similar charge, in not stating the quantity of cider vinegar used in proportion to the four ounces of water. We would like to be informed on these two points; as also, where he obtained "cold spring or branch water" at a temperature of 70° or 80° F.—(was the water first warmed?)

In conclusion, we would suggest a query in regard to the antiseptic properties of cider vinegar. Is not the action of the agent here used, namely, cider vinegar, rather a *chemical* than a *medicinal* one? Is not the ammoniacal state of the urine an alkaline condition, and does not the acetic acid contained in the cider vinegar neutralize the ammoniacal condition, and thus remove the exciting cause? This method of treating, and rousing up the latent energy of the organ, has been known to the writer for many years; and also the simple cold-water injections, which by their presence seem to excite the latent functional power of the organ, and thus stimulates to its contraction.

Respectfully,

C. H. VON TAGEN, M.D.,
Chicago, Ill.

ARMY NEWS.

GEO. W. CALLENDER, F.R.S., OF LONDON.—Prof. H. B. Sands gave a reception at his residence to Mr. Geo. W. Callender, of London, on the evening of Jan. 5, 1879. A large number of distinguished members of the profession were present, representing all the medical colleges, hospitals, dispensaries, as well as a number of leading private practitioners. On Saturday Mr. Callender visited Bellevue Hospital Medical College, and was persuaded by Prof. Sayre to make a few impromptu remarks. These have been presented in lecture form to our readers, in another place, page 25.

A NEW COURSE ON DIDACTIC DERMATOLOGY AT THE UNIVERSITY OF PENNSYLVANIA.—Dr. Louis A. Durling is at present engaged in delivering a course of didactic lectures on dermatology at the hospital of the University of Pennsylvania. The lecture hour is

between 4 and 5 on successive Saturday afternoons. The Dr. illustrates his lectures with rich specimens from his own private collections and from the George B. Wood collection in the Museum of the Medical School.

MEDICAL SOCIETY OF STATE OF NEW YORK—Delegates to and members of the Medical Society of the State of New York, who propose to present papers at the next annual meeting, will confer a great favor on the president and secretary, by sending, before January 15th, the title of their proposed papers, with the time they will occupy in reading them, to Dr. D. B. St. John Roosa, 20 East Thirtieth Street, New York.

NEW YORK ACADEMY OF MEDICINE.—At a stated meeting, held January 2, 1879, Dr. Fordyce Barker was elected President; Dr. James R. Leaming, Vice-President; Dr. S. S. Purple, Trustee; Dr. Charles Wright, Treasurer of the Board of Trustees; Dr. F. V. White, to serve in the Committee on Ethics; Dr. E. H. Janes, Committee on Admission; Dr. J. H. Hinton, Committee on the Library; and Drs. F. H. Hamilton and C. W. Packard, Committee on Education.

A memoir of the late **GEORGE WILKES, M.D.**, was read by Dr. Charles Wright. In the course of the memoir reference was made to the fact that Dr. Wilkes assisted Dr. Valentine Mott, who first successfully amputated at the hip-joint, and that the head of the femur was not disarticulated until the first dressing of the stump was made.

At the next meeting of the Academy, Jan. 16th, Dr. S. S. Purple, the retiring President, will deliver his valedictory, and Dr. Fordyce Barker, the President-elect, will give his inaugural address. It is requested that there be a full attendance, as some interesting and practical suggestions are to be offered, bearing upon the continued usefulness and future prosperity of the organization.

CHARITY HOSPITAL.—The Medical Board of Charity Hospital held their annual meeting for the election of officers at the New York Academy of Medicine, January 2d. The following officers were elected for the current year: President, Dr. Joseph W. Howe; Vice-President, Dr. Elsberg; Secretary, Dr. Robinson. Committee of Inspection: Drs. Frankel, Goldthwaite, Ely. Committee on Examination: Drs. Gillette, Howe, Otis, Ripley Robinson.

QUININE AND URTICARIA.—John Hunter, M.B., Milbrook, Ontario, writes: "Dr. Lente's article, in a recent number of *THE MEDICAL RECORD*, reminds me of two of my patients who were unusually affected by quinine in single doses of ten grains each. Both were females. The first was suffering from a severe attack of urticaria. She had taken other treatment for it. Quinine in above dose gave prompt relief, which lasted for some months. The second had symptoms of malarial fever. Gave her ten grains. She suffered the most intense pain in the head and in different parts of the body, with great prostration. She said it affected her in the same way some years before. These cases happened in my first year in practice. I was not aware then of the effects being of any special interest, otherwise I would have taken much fuller notes."

DEVIATION IN THE DEVELOPMENT OF THE VOCAL CORDS.—Dr. J. P. Creveling, of Auburn, N. Y., writes: "I trust the following description of a deviation in the development of the vocal cords will be of

sufficient interest to merit insertion in your journal. The subject was a male Indian, about thirty years of age, who died of tubercular deposit in lungs, with pneumonia. The larynx was removed entire, and divided posteriorly from above downward, between the arytenoid and through the cricoid cartilage. Folding the sides of the organ outward, a limited deposit of tubercular material was observed in the lower portion, mostly confined to the right side. The right vocal cord presented nothing unusual; the left was divided at its posterior third into a superior and an inferior fasciculus, the former passing upward and backward to the false cord, its fibres running parallel with and being inserted in common with that ligament at the anterior surface of the arytenoid cartilage. The inferior extended backward, and was inserted into the anterior angle of the same cartilage as usual.

The mucous membrane being carried upward along with the superior fragment, a third ventricle was formed, which was about one-third the normal size, covered with mucous membrane, and rather oval in shape. The free margin of the right vocal cord measured seven-eighths of an inch in length; the left, as far back as the division, nearly five-eighths; and each fasciculus a fraction more than two-eighths. The motion of the left cord was limited, and its free margin turned upward and somewhat outward, or into the ventricle proper. The case came under my observation a few days before death, but was so extremely feeble that an examination with the laryngoscope was not attempted, and although at that time unable to utter any audible sounds whatever, I am informed that previous to his illness his voice was good."

ANTIDOTE FOR ARSENITE OF SODA.—The ordinary antidote to arsenious acid (hydrated sesquioxide of iron) is wholly inefficacious in poisoning by arsenite of soda or potassa. The antidote to the latter is formed by the mixture of a solution of sesquichloride of iron and the oxide of magnesium. This mixture also answers for acid arsenious, consequently should always be preferred in arsenic-poisoning. Give the official sol. ferri sesquichlor., and afterward the magnesia. Give a cathartic an hour after the antidote. Avoid all acid drinks.

THE MÜTTER FOUNDATION LECTURES IN PHILADELPHIA ON SURGICAL PATHOLOGY.—Old Dr. Müttler, of Philadelphia, at his death, which occurred some fifteen or twenty years ago, made over to the Philadelphia College of Physicians and Surgeons, the sum of \$30,000 and his valuable collection of anatomical and pathological specimens, on condition that the college should erect a fire-proof building containing library accommodations, meeting and lecture rooms, and a museum. This was done in the year 1861, and since then the college has been enjoying the benefits of the endowment. The Doctor had provided in his will that \$600 out of the yearly accruing interest on the bequest should be set aside every third year as payment for a series of not less than ten lectures on some subject in surgical pathology, to be delivered by a member of the profession chosen by the college. The choice this year fell upon Samuel W. Gross, M.D., who divided his lectures into two series. The first series, consisting of six lectures, was begun on December 3d, and finished on December 17th. The first two lectures of the series were upon the "Development, Etiology, and Classification of Tumors," and the remaining four on "Sarcomas of the Bones." The second series, of four lectures, will probably have for

its subject "Tumors of the Breast," and be ready for delivery towards the end of the coming May. The third and fourth lecture of the first course are to be published in *The American Journal of the Medical Sciences* for April, 1879, and the fifth and sixth in the same journal for July, 1879. Dr. Gross proposes to publish a treatise on tumors at an early date. The Mütter lecturer for 1881 is Dr. Edward O. Shakespeare, the well-known Philadelphia microscopist and pathologist.

It may interest the profession to know that the famous dissection of the Siamese Twins, which was performed several years since by Drs. William H. Pancoast and Harrison Allen, of Philadelphia, at the request of the College of Physicians and Surgeons, and which cost altogether some \$1,100, including the expense of transporting the bodies of the twins to Philadelphia from their homes in the South, etc., etc., was entirely provided for out of the Mütter foundation.

A NEW AND SUCCESSFUL TREATMENT OF SHOCK.—Dr. Charles T. Hunter, Demonstrator of Surgery in the Medical School of the University of Pennsylvania, has lately introduced a new and successful treatment for the general shock following railroad injuries, etc. The patient is at once placed in a bath of 98° F.; the temperature of the bath is then rapidly raised to 110° F. As is well known the temperature of patients suffering from shock is as low as 96 in the armpit. By this method of treatment, Dr. Hunter has been able to raise the patient's temperature from 96° to 98½°, and to reduce his respirations in number from 36 to 20 in the minute. Before the bath, the skin is cold and clammy; on taking the patient out, it is warm and dry. The patient is kept in the bath from ten to fifteen minutes. This treatment has been followed in a number of recent cases in the surgical wards of the University Hospital.

FREE CHLORINE IN DIPHTHERIA.—Dr. B. L. Hartman, of Independence, Washington Co., Pa., after a rather extensive experience with diphtheria, and after finding that the usual remedies were powerless, says: "I concluded to try the chlorine in its pure state absorbed in a vegetable gum-water solution, as slippery elm or althea-root water. It is easily swallowed in this state, it is almost immediately absorbed, and its antiseptic and alterative action is at once perceivable. The effect was astonishing—the patient, a few hours before, rapidly sinking, revived in a short time. The fever and inflammation rapidly decreased. The specific discharge diminished, sinous gangrenous ulcerations took a more healthy appearance. The foul, stinking breath disappeared. The affected mucous membrane threw off its coating and discharged a more normal saliva, and in three to four days the most hopeless cases were out of danger.

This encouraged me to use it in all cases of diphtheria, and with proper sustaining diet and preparations of cinchona decoction, stimulants, etc., gargles of chlorate of potassa, alums, chlorate soda solution, salicylic acid solution, iodide of iron solution. After having pursued this treatment I lost but one patient, and he died of paralysis of the heart, two weeks after convalescence.

Formula: Aqua chlorate (Pharmacopœia Prussia), one oz.; Slippery elm water, or gum solution, 8 oz.

For a child from two to six years old, one dessert-spoonful every hour. For adults: Aqua chlorata, one oz.; Slippery-elm water, 6 oz. A tablespoonful every hour. Sustaining diet in small quantities every two to three hours, especially *milk*, and as soon as the mucous membrane is normal give stimulants in small

quantities, with iron and cinchona preparations. In paralytic affections *nuxvomica* or its preparations, as the case may require. I will remark before closing, that in nearly all cases I have noticed a peculiar tenderness of eyesight; and, in some acute cases, even total blindness for from a few hours to a few days, but disappearing always with a return to health."

CHAPPED HANDS.—Dr. M. A. Wilson of this city gives the following prescription for chapped hands:

℞ Acid carbol..... gr. xv.
Yolk of egg..... one.
Glycerina..... ʒ iij.

M. A small portion to be gently smeared over the affected surface several times daily.

The wearing of a pair of cotton or old kid gloves will much assist the recovery. The hands to be kept much as possible out of water. This mixture does not "spoil" by keeping.

DR. GEORGE A. RIECKER, a graduate of Jefferson College, Philadelphia, and for some time surgeon to the Panama Railroad Company, died in Panama on the 4th instant of congestion of the liver. He was a surgeon in the Northern Army during the Rebellion. The funeral services were under the charge of the Masonic body.

AIR OF HOUSE OF REPRESENTATIVES.—The physicians who attended the late Congressman Williams state that his illness "was entirely owing to the poisoned condition of the atmosphere of the House of Representatives, which he breathed constantly during the day, and to the malaria to which he was exposed at night, his private room being upon the south side of the avenue, directly over the water-sewers of the city." The public have suspected for many years that there was something wrong in the atmosphere of the House of Representatives.

INJECTION FOR GONORRHOEA.—Dr. M. A. Wilson, of this city, gives the following as his favorite prescription for gonorrhœa. He says it is most beneficial in the subacute stages, either recent or of long standing, but not of much service in *gleet*. All directions in regard to urethral hygiene, usually ordered in the treatment of this obstinate affection, are of course to be insisted upon:

℞ Zinci iodid..... grs. v.
Bismuthi subnit..... ʒ ij.
Mucil. gum acac..... ʒ iss.
Aqua dest..... q. s. ad ʒ iii.

To be well shaken.

M. S.—To be injected after each urination.

This is the strength most generally serviceable, but may be varied according to the judgment of the prescriber.

HYPODERMIC INJECTIONS OF TINCTURE OF ERGOT FOR RETENTION OF URINE.—M. Luton, of Rheims, employs a mixture of one part of tincture of ergot in five parts of alcohol at 90°, by hypodermic injection, in the treatment of inorganic retention of urine. The dose he employs is from seven and a half to thirty drops, fifteen drops of the solution being equal to three grains of powdered ergot. He has used it in the paralysis of the bladder accompanying typhus, confluent variola, and acute hydrocephalus. He makes the injection in the fossa behind the great trochanter. Within half an hour, and sometimes within a few minutes, a complete and forcible evacuation of the bladder takes place. He has never observed an eschar of the skin or a gangrenous abscess after the injection.—*Le Lyon Medical*.

Original Lectures.

ACUTE ARTICULAR RHEUMATISM.

TWO LECTURES DELIVERED BEFORE THE MEDICAL CLASS OF THE UNIVERSITY OF PENNSYLVANIA,

By ALFRED STILLÉ, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE.

(Reported for THE MEDICAL RECORD.)

LECTURE II.

THE CONSTITUTIONAL SYMPTOMS OF ACUTE ARTICULAR RHEUMATISM—THE DIAGNOSIS BETWEEN THIS DISEASE, GOUT, DENGUE, AND ARTHRITIS—THE PROGNOSIS OF ACUTE ARTICULAR RHEUMATISM—THE COMPLICATIONS OF ACUTE ARTICULAR RHEUMATISM—THE LITERATURE OF THE TREATMENT OF THE DISEASE; PURGATIVES, OPIUM, QUINIA, BLISTERS, SALICYLIC ACID, AND ALKALIES—THE MOST RATIONAL TREATMENT THAT BY ALKALIES.

I CONCLUDED my last lecture with a consideration of the local symptoms of acute articular rheumatism. The general symptoms are in proportion to the local symptoms, and in no other disease are they more marked. The pulse is from ninety to one hundred in cases of average severity, and is not very tense. In the usual run of cases the temperature varies from 101° to 104° F.

It is a very curious fact that with this high temperature the skin is bathed in a profuse sweat. This, of course, is entirely different from what occurs in other diseases. The perspiration is sour in smell, acid in reaction, may be either cold or clammy, and gives to the hand a marked sensation of pungency. The amount of sweat is generally in proportion to the height of the fever, but it cannot be considered as any criterion of the severity of the attack. The sweat of acute articular rheumatism is more profuse than that occurring in any other febrile disease which lasts for the same length of time.

To the sweating is partly due the increasing anæmia of the patient. This condition of anæmia gives rise to a murmur, which is not heard over the mitral valve, but at the base of the heart and over the aortic valve, and differs from the murmur heard in lesions of that valve. It is essentially a blood murmur, and is to be carefully distinguished from a mitral obstructive murmur.

The urine is usually scanty and high-colored, and laden with solids—urates and uric acid. There is commonly complete abhorrence of food, and great thirst. The bowels are generally much constipated. The constipation and thirst are both due to the excessive sweat.

There is very frequently some kind of an eruption accompanying attacks of acute articular rheumatism. Sudamina are very common. Erythema, both simple and nodose, occasionally appear; while upon still rarer occasions urticaria is found breaking out. This eruption has no special value as a prognostic symptom, or otherwise.

The face is flushed, and the eyes are bright, while the expression is one of acute pain. In the active stages of the disease the pain may bring on delirium by reason of its agonizing character.

When the disease was treated by venesection, as was formerly the case, the blood so drawn was found to be very florid in appearance, and threw up, upon al-

lowing it to stand, a thick and strong buffy coat. In some instances the proportion of fibrin in the blood was found to have risen from two and a half parts in one thousand parts of blood to five and even eight parts in the same amount. This great excess of fibrin in the blood is a very interesting pathological fact. In no other disease is the fibrin so greatly in excess.

There is but one plausible explanation of this phenomenon. It may be due to an arrested development of the white corpuscles, whose destruction would render intelligible the extreme pallor and debility of patients suffering from this disease; it being at present a seemingly well-established fact that the red corpuscles are formed directly from the white corpuscles. The loss of strength is due to the enormous waste of tissue brought about by the excessive discharge of solids in the urine.

After a variable period the pain and fever subside, the sweat moderates more and more, the thirst becomes less marked, the urine grows lighter in color, the effusion about the joints is absorbed, and the swelling subsides. Acute articular rheumatism is a disease which is not limited by days or weeks in its course. Be very careful, therefore, that you do not predict when your patient will get well.

If there is no relapse, the appetite will speedily return. If the recovery, however, is not so favorable, the effusion about the joints will remain; their fibrous tissue will become thickened, false ankyloses supervening, and movement of the affected parts becoming impossible. Particularly is this the case when the disease has been confined to a single joint, or when the same joint has been attacked several times by the disease.

The duration of acute articular rheumatism has been placed by some authorities at three months. The disease, as a general rule, will be found to be obstinate in proportion to the number of joints involved and to the frequency of the occurrence of attacks in the same joints.

THE DIAGNOSIS OF ACUTE ARTICULAR RHEUMATISM.

Acute articular rheumatism may be mistaken for the *arthritis*, produced by violence, or pyæmia. In both of these diseases the history of the causes and nature of the first attack ought to clear up all confusion with regard to the true nature of the malady. In arthritis there will almost always be found a history of some violence, or traumatic cause, or wound, or previous disease.

The fever and pain in the limbs render acute articular rheumatism something like *dengue*, or break-bone fever; but in this latter disease there is no swelling of the joints. In break-bone fever, too, there is always a papular eruption of the skin, which recalls measles, scarlatina, typhoid, and other fevers.

The disease from which it is most difficult to distinguish acute articular rheumatism is gout, though even here no one in the least familiar with the characteristic symptoms of the two diseases would be at all likely to confound them. Certainly not in acute gout, though possibly in an old, chronic case.

Rheumatism is chiefly produced by cold and wet; gout is never so produced. Rheumatism occurs among the poor and laboring classes; gout among the luxurious and indolent. Rheumatism attacks the larger joints, especially in its primary form, or else the small joints of the hand. Gout in its primary form invariably attacks the smaller joints, especially that of the great toe. In rheumatism there is no gastric disorder; in gout gastric symptoms are common. In rheumatism there is profuse acid perspira-

tion; in gout there is no perspiration at all, and the skin is hot and harsh. In rheumatism there is a secretion by the skin and elsewhere of *lactic* and *uric* acids; in gout there is only a secretion of *uric* acid by the kidneys, though I will not say that this uric acid is not also secreted by the skin, for it circulates freely in the blood. There is no tendency to saline and chalky deposits in the joints in rheumatism; in chronic gout there is such a tendency. In rheumatism the bursæ and joints are swollen; in gout the swelling is confined to œdema of the skin. In rheumatism the color of the affected joints is light red; in gout the redness is intense and dark. In rheumatism there is no permanent enlargement of the parts; in gout this is always so. In rheumatism the remissions are of very slight duration; in gout they are very marked, the patient imagining himself quite well in the intervals.

THE PROGNOSIS OF ACUTE ARTICULAR RHEUMATISM.]

Acute articular rheumatism is not a dangerous disease in itself, though one attack increases the liability to the disease. The mortality in uncomplicated cases of acute articular rheumatism is only about four per cent. Where the disease is fatal in itself, it is generally due either to the excessive pain acting on a weak constitution, or to the so-called *hyperpyrexia*, the cases in which the temperature mounts up rapidly to 108° or 110° F., or to the exhaustion of the brain and the heart. The danger of cardiac inflammation is greater in the young than in the old. Repeated attacks produce a permanent rigidity of the joints, and render the valvular lesion worse each time. There are very few second attacks which do not settle upon the same joints which were affected in the first attack, and make an additional deposit upon them.

THE COMPLICATIONS OF ACUTE ARTICULAR RHEUMATISM.

The complications of the disease would form a very interesting study, but I have not time to enter upon a full consideration of them.

Among them may be mentioned chorea, or St. Vitus's dance, which is more or less marked in severity and an especially common complication in children. This disease, as an accompaniment of rheumatic affections, is more common where the heart is affected than where it is not.

Acute articular rheumatism is a peculiar inflammation of the capsules and ligaments investing the joints. This inflammation may be transferred to any similar tissue elsewhere. All the serous and fibrous membranes of the body are exceedingly liable to be inflamed, hence the frequency of peritonitis, pericarditis, endocarditis, pleurisy, meningitis, or bronchitis, as complications of rheumatism. In these cases, where internal organs are attacked, the local rheumatic symptoms are not in the least diminished—the patient has two diseases to suffer instead of one. Of all the complications meningitis is the least frequent, while pleurisy and bronchitis are the most common. Rheumatic pleurisy with bronchitis is very intractable. Such a pleurisy is more likely to be double than any other form of pleurisy. Rheumatic bronchitis also is apt to be very severe, for, unlike common bronchitis, the whole extent of the bronchial mucous membrane is affected, and the oppression is greater than in any other form except plastic bronchitis. The cough, too, is racking and unproductive.

Attention was first called to rheumatic heart-affections by Pitcairn, of London, and the close connection between the two diseases demonstrated. Again, in

1820, Dr. James Johnson insisted upon the same thing. The celebrated Bouillaud, of Paris, was the first, however, to prove beyond a doubt the nature and reality of the inflammation, although he exaggerated the frequency of the occurrence of endocarditis. The explanation of this exaggeration lies in the fact that at that day all murmurs heard within the heart were supposed to be produced by inflammation of the organ, whereas they often depend upon changes in the blood. Bouillaud called attention to the deposits made in the heart in the *post-mortem* inspection of persons dying of the disease, especially upon the leaflets of the mitral valve. Pericarditis or endocarditis he supposed to occur about once in every five cases of acute articular rheumatism. The signs of endocarditis are sometimes obscure and doubtful; it cannot be proven to exist on the strength of an endocardial murmur, which may be either functional or organic; or, again, the murmur may be caused by the attachment to one or more of the valves of more or less of the fibrin which is circulating in the blood. It is now settled that if there is no increase of the general symptoms at the time there is no proof of the existence of endocarditis.

The cerebral complications of acute articular rheumatism are thus described by Fuller: A patient with acute articular rheumatism passes a week or two with no untoward symptoms, until, after several nights of flightiness, maniacal delirium occurs, in the course of which he throws his limbs about as if they were insensible to pain. If the patient does not improve, he falls into a state of coma, and dies from exhaustion. In such cases no evidence of inflammation in the brain is found after death.

Sometimes, owing to the excess of fibrin, coagula form in the heart, and become the cause of alarming and distressing symptoms. Emboli being so formed, may be carried perhaps into the brain and other organs.

THE TREATMENT OF THIS AFFECTION.

At the outset of this part of my discourse, I desire to lay great stress upon the statement that *the treatment of simple acute articular rheumatism may be abandoned to palliatives and nature*. Apart from complications, such cases nearly always get well under rest and good nursing. Try and disabuse yourselves of the idea that their cure is dependent upon medicines alone; to help nature is often the best we can do. No treatment was ever invented which stopped a case of acute articular rheumatism. It cannot be accomplished by bleeding, or sweating, or purging, by nitre, by tartar emetic, by guaiacum, by alkalies, by salines, by salicylic acid, or by anything else. The physician can palliate pain and perhaps shorten the attack; can perhaps prevent or control complications, and stiffness in the joints, but he cannot arrest the disease. Where rest, proper diet, and warmth are enjoyed, most cases will get well just as soon without as with the use of other remedies. Dr. Austin Flint, of New York, in support of this statement, subjected some patients, a number of years ago, to the expectant treatment, and found that they made just as rapid and just as complete recoveries as those cases under active medication.

Purgatives have been used in all ages in the treatment of this disease, because it was considered to be a fever. We are all too apt to put our necks into the yoke of a theory. In old times they thought that the system ought to be reduced. Before the time of purgatives depletion was employed. This mode of treatment I will not even discuss. There is no evidence that I know of in favor of purgatives. There are

very good reasons, indeed, why they should not be used: (1) because they cannot possibly cure; (2) because they oblige the patient to make painful movements; and (3) because they expose him to the danger of cold.

A celebrated London physician had all his patients packed in blankets, and did not allow them to move a finger. This was going to the other extreme.

There are certain cases in which purgatives are alleged to be of use, viz., those in which the bowels are constipated, and there is a bitter taste in the mouth. I have never seen such cases except in habitual drunkards, and in their case a purgative does more harm than allowing the effete matter to remain in the system.

Opium was once vaunted as a specific, and it was claimed that it diminished the complications of the disease. Dr. Corrigan, of Dublin, said that large doses of opium were well borne—say from four to twelve grains in the course of the twenty-four hours, or sometimes he advised giving as much as one grain every hour. Opium so employed does not produce narcotism, and does not constipate the bowels. More recent experience has shown that opium, of all remedies, is the most likely to cause complications in the heart.

Some have recommended colchicum, arguing that because it does good in gont, it must therefore do good in rheumatism. But colchicum is not a remedy for rheumatism.

Many years ago it was very much the custom to administer large doses of powdered Peruvian bark. The rationale of these large doses was founded upon their sedative effect. Haygarth, Morton, Heberden, and Fothergill were the first to employ this method. Later still, a number of noted French physicians, among them Briquet, Andral, Moneret, and Legroux, renewed the use of this medicine in the form of quinia, but gave it in smaller doses, seeking only its tonic effect, from five to fifteen grains being administered in the course of twenty-four hours, and then it was continued in smaller doses.

Still more recently, quinia taking the place of Peruvian bark, the old plan of administering large doses has been resumed. From thirty to one hundred grains have been administered in the course of twenty-four hours. Never was there a more profligate waste of a precious medicine. Even the physicians who so used it were obliged to acknowledge that it only did good in subacute and mild cases.

I believe that it has also been fashionable in the so-called cases of *hyperpyrexia* to immerse the patient in a bath varying in temperature from sixty to ninety-eight degrees Fahr. Although patients thus treated sometimes recovered, they also sometimes perished from congestion of the lungs and brain.

Among cardiac and nervous sedatives, digitalis, veratrum album and viride, veratria and aconite, have at one time or another been employed indiscriminately. Such treatment, of course, has only proven itself to be a monument of rashness to those who employed it. Such sedatives may reduce the pulse, but do not shorten the disease. Indeed, if it is possible to prove the absurdity of anything more clearly by mere enumeration of these medicines as cures for rheumatism, I do not know of it. Do digitalis and aconite act in the same manner? This is just one expression of the folly which has surrounded the use of digitalis at its first discovery. Every affection of the heart was treated by digitalis.

Within the last few years new remedies have been proclaimed in salicylic acid and its sodium salt. I

confess that I possess no personal knowledge of their use in this disease, for I was at first dissuaded from employing them by a prejudice against the grounds on which they were recommended, and more recently by the contradictory judgments respecting them, and the unquestionable mischief they have sometimes caused. According to their eulogists, the arrest of the disease is secured by them within four or five days, whether the attack be febrile or not; its mortality is diminished; relapses do not occur if the medicine is used until full convalescence; it is without influence on heart complications already existing, but it tends to prevent them as well as other serious inflammations. One of these gentlemen assures us that to say it far excels any other method of treatment would be to give it but scanty praise. But, upon the other hand, it is accused of producing disorders, and even grave accidents, in almost all the functions of the economy. In some cases it has caused ringing in the ears, or deafness, or a rapid pulse, or an excessively high temperature, panting respiration, profuse perspiration, albuminuria, delirium, and imminent collapse. In one published case, this antipyretic did not lower, but, on the contrary, seemed actually to raise the temperature so high that immediately after death it stood at 111° F. Many, very many, analogous cases have been published. I repeat, therefore, that I am personally unacquainted with the effects of this medicine in acute articular rheumatism, and that I have not, thus far, been tempted to employ it.

BLISTERS AND ALKALIES THE MOST RELIABLE REMEDIES.

It may be difficult to see the connection between these two classes of remedies in their power to influence the course of acute articular rheumatism, and yet it is certain that they do so influence it, and in the same way, *i. e.* by altering the condition of the blood from acid to alkaline. If you ask me to explain to you how blisters act in this way, I am obliged to confess my ignorance. To produce this effect, they must be applied over all the affected joints. Experience, if not science, has decided conclusively in their favor. They do produce a cessation of the local symptoms, render the urine alkaline, and diminish the fibrin in the blood.

This brings us to a consideration of the use of alkalies. Alkalies neutralize the acids, act as diuretics, and eliminate the *matrices morbi*. Alone, and in small doses, they are unable to cure; but, when given in very large doses, their effects are marvellous; the pulse falls, the urine is increased in quantity and becomes alkaline, and the inflammation subsides. The symptoms of the disease are moderated, the duration of the attack is shortened, and the cardiac complications are prevented.

The dose of the alkalies must be increased until the acid secretions are neutralized. A very good combination of these remedies is the following.

R. Soda bicarb.....	℥ iss.
Potas. acetatis.....	℥ ss.
Acid. cit.....	℥ ʒ ss.
Aque.....	℥ ʒ ij.

S.—This dose should be repeated every three or four hours until the urine becomes alkaline. On the subsidence of the active symptoms, two grains of quinia may be added, with advantage, to each dose. The alkalies must be gradually discontinued, but the quinia continued.

The diet should consist of beef-tea or broth, with bread and milk; no solid food should be allowed.

Woollen cloths moistened with alkaline solutions may with advantage be applied to the affected joints. To these laudanum may be added for its anodyne effect.

The patient must be sedulously protected from vicissitudes of temperature, and lie in bed between blankets.

The alkaline treatment relieves the pain, abates the fever, and saves the heart by lessening the amount of fibrin in the blood.

A long time ago Dr. Owen Rees, of London, introduced the use of lemon-juice. This remedy was thought to convert uric acid into urea, and so to help elimination. Though the treatment is practically right, the theory of it is wrong. Lemon-juice does good in mild cases, but cannot be relied upon in severe attacks.

During the febrile stage of acute articular rheumatism the diet should consist mainly of farinaceous and mucilaginous preparations, with lemonade and carbonic acid water as a drink. The cloths applied to the joints should be changed when they become saturated with sweat, and in changing them the patient should be protected from the air.

The sweating may be controlled by small doses of atropia, from one-sixtieth to one-thirtieth of a grain. To prevent subsequent stiffness, the joints should be bathed with warm oil and chloroform, and wrapped in flannel cloths. In the proper season this condition is very well treated by sea-bathing. There is no specific plan of treatment in acute articular rheumatism. The treatment must vary according to the intensity of the inflammation and the peculiarities of the patient.

Original Communications.

THE PROPHYLACTIC TREATMENT OF INDIVIDUALS AS A MEANS OF PREVENTING EPIDEMICS OF YELLOW FEVER OR OTHER INFECTIVE DISEASES.

PAPER PRESENTED TO THE PUBLIC HEALTH ASSOCIATION, RICHMOND, NOV., 1878.

By EZRA M. HUNT, M.D.

As to all infective diseases, four questions are prominent: I. Origin; II. Modes of propagation; III. Methods of prevention; IV. Treatment.

In this paper we shall not discuss the origin (I.). We shall take it for granted that the *mode of propagation* (II.) is by infective particles, mostly received through the air-passages, which, passing into the human system, produce that toxic and abnormal condition which constitutes the disease.

The treatment (IV.) we leave to be discussed by those who, after heroic contention with the recent epidemic, still live to contribute their experience.

Our present intent is only to inquire as to methods of prevention. To this inquiry there are many prompt replies.

Those, for instance, who regard yellow fever as an infection, imported every time it first appears, fasten attention on the marine. To such—so far as the United States is practically concerned—that is the origin, and such propose its abolition coastwise. That may be so; and all along the line we would put the forces of sanitary art on duty, as if that were the *direction of danger*.

But so often has the enemy entered while watched, so hard is it to watch so as to prevent landing atoms or molecules so small that the microscope and the Tyndall light reflectors have not revealed them, and so variable are the convictions of skilled students of epidemiology, that by common consent other methods of prevention are not to be dispensed with.

The second answer is: prevent by cleanliness of surroundings—purity everywhere. Not one whit would we demur from that enforcement. But we are to remember that massed population, without *any* animal organic matter around, and vast areas of territory without *any* accumulated vegetable decay, are difficult of realization. To remove or disinfect all such decay is a herculean task. If infective particles only await the coincidence of heat, moisture and accumulated decompositions, they stand large chances of finding these somewhere. The effort is to be made, because partial success means limitation; but we may not entirely trust to this for the abolition of infective diseases.

Is it not also well, just here, to note that with all that is said about FILTH, yet the infective particles, having been originated elsewhere and arrived in cargo, it is yet to be proven that outside filth is the soil for such particles. Is not the soil in the individual? Does not the infection go straight for the human being as its place to feed, and grow, and display its sad vigor of force? It is not *dependent* upon collateral outside aid now. The vicious entity has arrived as a plenipotentiary. For display of power it only needs a man, a woman, or a child, even if occasionally accepting the aid and abettal of outside servants. We believe that filth is evil, and only evil, and that continually, and that it often assists to intensify infective diseases, but more because it embarrasses individuals in their resistance than that it invigorates infective particles for the higher organism on which they feed, and to which they, by their own ill instinct, resort.

Sir Thomas Watson, Bart., M.D. (1877), goes so far as not only to call the *body* the soil in which the infection finds its sought-for nidus and food for growth, but accounts for the *single* attack of many infective diseases, on the view that the first seizure exhausts some one or more of the indispensable ingredients only to be found in the man.

The next reply, and the most usual resort, is *treatment*. It hopes to limit by staying the progress and abating the severity. This, though not preventive to the individual concerned, does probably limit the production of infective particles, and result in fewer seizures. But new discouragements await us. Some of these infections, like plague and yellow fever, so rapidly change vital fluids, or congest or disorganize, that the system is incapacitated for the appropriation of remedies so as to obtain their physiological and medicinal effects. In yellow fever, for instance, the earliest and radical changes are in our great dependency, the blood. It is a blood-poison (Schmidt). With the introduction of a foreign irritative there is rapid decomposition, *i. e.*, separation of its constituent parts, impairment of the blood-paths to the remotest arterioles, and paralysis of the vaso-motor nerves (Huxley, p. 62) which control them. The blood is very early acid, the red corpuscles are diminished in size, shrunken and crenated, and their coloring matter becomes free in the blood, thus changing from hemoglobin to hematin. The fibrin is diminished so as not to coagulate; the walls of the vessels lose tone, and show germination of the nuclei of the muscular coat of the arterioles, and early fatty degeneration (compare Klein, p. 47). Organs are

affected not so much specially (idiopathically or primarily) as by virtue of a tendency to congestion consequent upon the primary toxic shock on the blood and its ducts.

I happened to be reading side by side the report on the minute anatomy of twenty-three cases of malignant scarlatina by Klein, and similar examinations of yellow fever by Schmidt, etc. (Privy Council, New Series, No. 8, 1876, p. 21; *N. C. Journal*, Sept., 1872 and 1873), and could not but be impressed with points of comparison.

Here is one: It would seem as if, "under the influence of some stimulus (perhaps some blood-irritant) which the disease supplies, the arterial muscular tissue has been exceptionally exercised. Query, whether this exceptional exercise of contractility affecting the calibre of the arterioles may, during life, shut the glomeruli out of the circulation, and may thus, so far as it operates, suppress the secretion of urine." See Klein, p. 58.

Prof. Joseph Jones, *N. C. Med. and Surg. Journal*, Sept., 1874, notices "the rapid putrefaction of the blood of yellow fever after its abstraction from the living body, as also the rapid dissolution of the colored blood-corpuscles."

The hopelessness of treatment in severe cases is inseparable from the involved lesions of the disease. It is much the same as with the concealed imbibition of an acid poison, for it thus impairs structure as much as does a fretful corrosive in contact with living parts. If we had antidotes we would be too late.

In view of all these facts, as to the incompleteness of our prevention, by coast guard, by cleanliness and disinfection, and by after-medication, we are almost driven to ask whether we may not turn from surroundings (circumstances) and come to deal with individuals before the manifestation of disease.

Is it not worth yearning inquiry if we cannot put individuals in such a condition of unreceptivity as to exempt them from seizure, and so not only save them, but thus limit the disease below epidemic proportions, and in the end, by all the methods combined, accomplish well nigh its subjugation?

Such limitations do take place in nature. Unsusceptibility to attack under actual exposure is not a mere fortuitous circumstance; we recognize it as acquired by the individual when we call him acclimated.

That protection must be of an internal character. Such limitations are often established when a disease once had secured immunity from any subsequent attack.

It is not unthinkable that somehow we too may put the individual in at least such temporary condition as that the infective particle will not alight upon him, will find a surface on which it cannot or will not operate. That we do not do this after a disease has made alteration of structure and accomplished suspension of function, is not surprising. Nor is it at all strange if the same remedies, which are useless or feebly operative or positively injurious in the disease, might yet avail before its outbreak.

What then can we do to the individual so that when the particulate or molecular infection comes along it shall find a surface unfriendly to its lodgment, or the blood and secretions or the membranes so preoccupied, prepossessed, pre-empted, that the disease cannot take hold? There is an answer which has to do with mechanical prevention. If cotton-wool will detain saprophytes, we can conceive how, were it practicable, the air-passages might have infective particles strained out and left without.

But more practically we may look to the entrance-chamber for all air and food. The mouth, the glands,

the lymphoid follicles, the character of the membrane, its whole series of absorptive apparatus, as revealed by histology, and the manifestations which in some infective diseases do take place just there, and the evidences in others of absorption from thence, cannot but excite watchful inquiry. That is a suggestive remark of Dr. Wm. Farr, in the Thirty-eighth Annual Report of the Registrar-General of England, when referring, as he calls them, to "the seeds of zymotic disease," he says: "Inspiration bringing them into contact with the mucous membrane of the nose, throat, and air-tubes, easily infects the moist surfaces with their venom" (p. 232). There are some infective particles which are local in effect, as well as conveyed by absorption, before they are wholly constitutional. With infectives which enter from without, it applies to the individual as well as to the State to guard the port of entry.

Since it is possible that infective particles might be detained mechanically or affected chemically, or if living matter, like other animals or vegetables, might have their instincts or choices of locality, or that corrugated surfaces, or certain odors or presences, might prevent activity or absorption, the question is not irrelevant; whether we may not, by dealing with the most accessible mucous surfaces, which all these particles have to pass over or lodge upon, somehow embarrass entrance or suspend their proclivities. But in a disease like yellow fever more important is the question whether the setting up of those absorptive, proliferative changes which the poison would initiate, cannot be prevented by introducing beforehand and securing the sustained presence in the blood and system of substances inimical to the infective particles in their attempted occupancy and disorganization. Now note a few facts from competent observers, not offered by them in support of a hypothesis, but occurring in the course of other investigations.

Prof. Polli, of Milan, in his paper before the British Medical Association, 1877, entitled "Observations on the Treatment of Zymotic Diseases by the Administration of the Sulphites," showed by his experiments that the bodies of animals that had been fed on the sulphites resisted putrefaction longer than similar animals not so fed, and so rendered it probable that certain resistive conditions can be maintained in the living body for a time (although he did not hint at the application of the principle to the prevention of disease). Still more suggestive is the fact that urine passed by the animals while living "did not undergo ammoniacal fermentation for eight days during the hot Italian summer."

Is it not tenable to ask whether we may not, by infusion of the blood, interfere with septic infections before they have crippled our power, and thus prevent their recognizance or make the malign benign?

In a recent discussion which took place at the Paris International Congress of Hygiene (1878), M. Bugy alluded to his own careful watching through several cholera epidemics as to the singular exemption of workers in copper. He had himself satisfactorily experimented with it. "The point was to become impregnated with the copper—to have a certain quantity in the system—so as to obtain immunity." He explained the escape of Aubagne, between Toulon and Marseilles, from three cholera epidemics in this way. M. Mormisse declared his confidence in this prophylaxis. (See *London San. Record*, Aug. 16, 1878, p. 106.)

The influence of continuous doses of arsenic in suspending the effects of vaccination, and its value as a prophylactic in an epidemic of rinderpest, is claimed

as a result of experiments and observations by E. J. Syson, English Medical Officer of Health.

Some reputable observers in our country, as alluded to by Prof. J. G. Cabell, in his late address before the American Medical Association, have been hopeful in their success with other prophylactics in diphtheria and scarlet fever.

So good an authority as Prof. Binz claims that the antipyretic action of certain articles is a result of their antiseptic power. (See *Lond. Prac.*, XVI., p. 443, quoted *Phil. Med. Times*, Sept. 28, 1878.)

But we scarcely need to look thus far for evidence.

If we follow the clinical history of cinchona, we find that, from being ranked as a specific or antiperiodic, it has come to vindicate and define itself as an article introduced into the blood, which interferes with the domination of at least one specified infection. Chill and fever is admitted to depend upon infective particles received from without. Susceptible persons, who have never suffered an attack, are prevented therefrom by the introduction of the alkaloid as a prophylactic. This distinctly means that one outside infection known to be able to initiate and carry on prolific diseased action is deprived of that ability and suspended in its exercise of power by dealing with the individual easier than by dealing with his surroundings. It is the unimpeachable witness that in one notable class of cases it is possible to place beforehand in the blood, and, by repeated doses, keep present there, that which does suspend the animation of at least one infection, and so prevent the disease.

This is so well admitted that, as a reminder, we only need to refer to such a summing up and such an example as that recorded by Prof. H. C. Wood, Jr. (See *Materia Medica*). "The value," says he, "of the daily use of quinine to persons exposed to a malarial atmosphere has now been thoroughly tested in all portions of the world. The testimony is unanimous in its favor." A single citation will serve to illustrate the fact. Dr. J. B. Hamilton (*Indian Medical Gazette*, Nov. 1, 1873) reports the case of a battery of 135 men quartered at Jubbulpore, East Indies, in the same barracks with an infantry regiment. Each of the artillerymen received three grains of quinine every other day; to the infantrymen none was given. The result was, that whilst 300 out of 500 men of the regiment were sick at one time with malarial disease, at no period were more than four per cent. of the battery affected.

Says Prof. R. Bartholow: "Quinia is used to prevent malarial infection. Numerous instances have been reported in which those using quinia as a preventive of malarial poisoning have experienced an exemption from malarial diseases when exposed to the most deadly miasma." *This great outstanding fact that there is one article which, given in advance, can vacate one infection, is never to be lost sight of in thinking of an epidemic.*

Because it so happens that quinine also aids to overcome the developed disease, we are not to obscure it as a prophylactic to at least one infective.

It is always possible, and in some degree probable, that the same article which acts so as to supersede an infective particle, and so prevent its self-assertion, will also act as a restraint, or as a curative, in maladies where the first paroxysm is not destructive, or the toxic tends to expend itself without malignancy.

But, because any article does not prove a remedy in an attack, we cannot infer its inertness as a preventive.

In some infections the era of manifestation is that of indisputable supremacy. The force is so explo-

sive, the tainting of fluids and the disorganization of vital parts so early, or the exacerbation so distant, that we cannot hope to suspend an action hastening to the bitter end. The prophylactic in the severer cases may even prove an irritant, just as restoring food will irritate a perverted stomach.

That quinine has any superseding effect, after a malarial infection has had constitutional manifestation, is far more likely, owing to its less pernicious endowment and its periodicity of activity, than to any specific relation between this one infection and the alkaloid itself. While each kind of infection has its characteristics, yet they are allied in their methods of dealing and in their effort to set up septic processes.

We are greatly interested in experiments by Mayer, Hallier, Herbst, Polli, Binz, etc., which show the wonderful protective power of quinine before any infective action has been declared. In the proportion of 1 part to 300, it will preserve milk, urine, albumen, etc. It acts upon infusoria as well as upon the ordinary mould or fungi.

It may as appropriately be called anti-infective as antiseptic, quelling that movement which is the process by which the infective molecules of the in-breathed poisons do initiate their work and accomplish their virulence. Through the blood, in an embarrassed state, "the cinchona alkaloids diffuse with great rapidity." Increased fluorescence is discernible in the crystalline lens in a half-hour after its administration, and as soon as that it is also present in the urine. It is possible even by small doses to maintain for a length of time its presence in the blood, as it is easily held in solution, or minute division in it, B.). "Recent researches have quite accurately demonstrated the nature of the action of quinia on certain constituents of the blood. It is a protoplasmic poison" (Bartholow, M. M., p. 127). It tells upon cells and all amoeboid movements (compare Frey, p. 12). Amoeboid movements are checked by it when only 1 to 4,000 parts is present. It impedes those blood-changes which are a part of the noticed effect of most infectives in their initial work (see Wood, pp. 60 and 61). It acts forcibly on all animal germinal matter, as well as upon the fungi which are the immediate cause of so many destructive changes.

With such facts as to a substance which it is possible to maintain for a considerable time in presence in the blood and secretions, and with the fact certified beyond dispute, that at least one class of infective particles, having entered into our being, are circumvented, suspended, and, so, any manifestation of disease prevented by this antecedent treatment, *have we not a prophylaxis of the individual which should make us intensely hopeful as to all those infective diseases received from without in a similar way?*

While there are destructive infective particles put in from without, there are also preservative and conservative particles to be put in which establish and maintain a condition of resistance.

What acclimatization does; what once having a disease often does; what vaccination does; and, most of all, in its present bearing, what quinia given in advance does, to prevent demonstration by the infective particles of malaria, make it not chimerical to be intensely hopeful that some other infective particles may be prohibited from that exercise of their power which is the fatal disease, by timely infusion into the blood of antagonistic elements which, in order to be timely, must be antecedent, prophylactic.

Two other articles may be alluded to as illustrative of the seeming control which can be exercised by a

continuous presence in the blood of antagonists to infective developments.

Chlorate of potassium, there is reason to believe, interferes with the action of infective particles. It is easy of absorption and maintenance in the blood "if the stomach be in a condition to absorb anything"—Barker, p. 410. Isambert found it in the saliva in five minutes after ingestion; in the urine in ten minutes, in which it continues from fifteen to forty-eight hours; in the nasal mucus, the tears, and the bile. Its power of permeation and harmless sustentation, and its aid in disposing of the products of change, so as to render them innocuous, is most manifest. It dissolves albumenoids, of which many conceive infective particles to consist, and insures the gradual oxidation of the organic constituents of fluids (B., M. Med., p. 638). Its introduction as a medicine (see West), its power over aphthæ and ulcerative stomatitis, the identification of cryptogamous growth (Gruby, Berg. Condie; Watson, p. 485), and Niemeyer, Chap. 1-8, Vol. I, p. 414-430) and fungi in some of the diseases over which it has chief control, are in accord with its hoped-for power over morbid processes dependent upon inhaled infections.

Tincture of chloride of iron—tinct. ferri chloridi—is another of the articles to be hopefully watched as likely to fortify the system against susceptibility to some infective particles and to prohibit the rapid disintegration which they attempt.

As preventive of the sedation or coaptation of infective particles to mucous surfaces, its corrugating and antiseptic effect is such locally as to interfere with implantation and absorption. When in the blood, it not only increases the contractility of the vessels mechanically, but also aids their vital contractility.

Our power to modify the condition of the blood by the use of this agent has received some interesting certification more recently.

The white and red corpuscles are seen to play not only the important rôle in health, but to be subject to great disturbance and diminution in rapid infective diseases. By means of Mal-us-sez, "Compte-Globules," or Globule Reckoner, or with the Hæmacytometer (see *Phil. Med. Times*, Sept. 28, 1878, p. 623), we can see what takes place under the administration of iron. The experiments of Rabuteau, in Paris, and of his confères (see cit.), and of Prof. Gowers, of London, show what control we may thus exercise over blood-conditions. Even white blood-corpuscles can be made to take up small foreign particles (see Frey's Histology, p. 24). Our own prophylactic use for diphtheria and scarlet fever has been highly satisfactory. It seems to act directly "on the blood as an ozonizing agent." The chloride of iron, well laden with oxygen, chlorine, and iron, and having, in addition, muriatic acid, alcohol, and muriatic ether (W., p. 81), is resistant of infective degradations, and only fails in some of them as a remedy, because already its power is surpassed and outridden by that of the infection and by the inability of the diseased vessels to deliver it.

We allude to these as illustrations of hopeful prophylactics, to which not unlikely may be added sulphylic acid, arsenic, alcohol, sulphurous acid, and some sulphites and chlorides found to have some restraining prophylactic power in general or in special adaptation to some classes of infectants, even though they entirely fail as remedies.

Our desire in this presentation is to draw special attention to the dealing with the exposed but unat-

tacked individual amid rapid and destructive epidemics, instead of only with everything outside of him. The scourge is so portentous and the ravages so dire, that, while not neglecting any outside methods, we would be inquisitive as to what can be done upon the individual who cannot betake himself to flight.

May we not closely study his personal cleansing by detergent and antiseptic methods at his points of contact with the infected atmosphere about him? May we not ask how we may guard the common avenue of approach and protect its membrane, and all the more since in yellow fever the inbreathed air is esteemed the common carrier of the infection?

Shall we not most of all emphasize the facts which justify us in testing and asking others to test our ability to suspend the infective process by having present in the blood organs or tissues, such catalytic substance as shall either destroy the infective particle, or, as this is not essential, so stupefy, embarrass or suspend it, that it shall not be able to set up critically that morbid series of actions which constitute the violence of a disease.

The article of Dr. P. Selis, of Havana, as quoted in the *N. O. Medical and Surgical Journal*, Sept. 7, 1878, in reference to the Preventive Treatment of Yellow Fever in Havana, deserves to attract attention.

The ground of such hope is quite different from the hypothesis of specifics for each disease, but is based upon what does actually take place in prevention of malarial attacks, what is asserted by respectable authorities to have occurred as to diphtheria, scarlet fever, etc., and what may attach to many articles by virtue of their ability to infuse into the blood a resistive principle.

This is far more probable since we have come to know that we can for days maintain in the blood certain substances, which are known to interfere with the progress of changes similar to those which infective particles set up, and can perceive uniformity of effect if only the element is introduced before the toxic has embarrassed or nullified its capacity by changes already wrought.

After once having secured the presence of some such substances as we have named, as manifested in the saliva, urine, etc., it takes exactness of method and real discipline of administration, but very small doses, to maintain this action up to the point of securing resistance or benignancy.

The embarrassment to any one proposing such a method is, that so many claim to have tried these as remedies without avail, and so infer against their prophylactic value, or else have made trials in this direction which lack precision, continuance, and sufficiency of numbers.

We shall never lose the expression of Prof. Lister, as, one day, in his own Edinburgh University Hospital, he said: "I am always willing to be informed by the testimony of capable observers and accurate manipulators; but so many annoy me by having *someone* used an antiseptic, and then telling me they have tried my method without success. When I come to find out what they have tried, I generally find that they have tried piecemeals, and these piecemeal failures should only stand as the tokens of inadequate trial and imperfect details."

It is just so with very many prophylactic trials in the past. There have been a few exact observers and a few trials which, as far as they go, have been expert; but there has been too great paucity of cases, as well as too few who have observed and tried *this* preventive method on a plan.

What we want is, that a large number of persons

in an infected locality shall be put under exact individual prophylaxis, under continuous medical supervision, with prescribed conditions of test. It will not do to rest on doubts and denials, accompanied by no particulars which will enable others to arrive at conclusions, nor, on the other hand, to accept without items such a statement as that of the New Orleans correspondent of the *Times*, who, under date of Sept. 20th, says: "There has been sufficient evidence adduced to show that quinine is prophylactic. One orphan asylum, containing fifty-six children, has not had a case so far. Since the outbreak of the epidemic each child has been constantly under the influence of the drug. Within your correspondent's knowledge there are fourteen unacclimated persons who have thus far escaped, although constantly exposed, who have regularly taken six grains of quinine a day in conjunction with 'arsenic.'" We since find the evidence still stronger.

All we claim is, that, with the facts as we have stated them before us, the time has come when we should be ready for a precise method of prophylaxis in the first epidemic, such as shall confirm or disprove views that are entertained.

Early in the recent epidemic some such views were expressed by us and forwarded with courteous attention; but the variety of other suggestions and the emergencies of multiplying cases and deficient aid, prevented satisfactory trial.

If only thus we can prevent—*i. e.*, go before the infected particle has had individual manifestation, as does quinine before the infection of malaria—we shall assist the other methods practised in a most radical and important way, and add to future hopefulness in the limitation of all infective diseases.

TWO CASES OF VARICOSE VEINS OF THE LOWER EXTREMITY, TREATED FOR RADICAL CURE AT THE PRESBYTERIAN HOSPITAL,

By ALFRED C. POST, M.D.,

VISITING SURGEON.

CASE I.—James Johnston, laborer, *æt.* 45; admitted April 9, 1877.

Patient has had varicose veins on his right leg for the last twenty-five years. An ulcer appeared five years ago, on the external and posterior surface of the leg, and has remained open since that time. At different times other ulcers have occurred and have healed.

Present condition: Patient is a man of large stature, but of pallid complexion. Cicatrices of former ulcers are seen on both legs. There is an unhealthy ulcer, of the size of a silver half-dollar, on the posterior and external aspect of the right leg, about five inches above the ankle. On the inner side of the calf of this leg may be seen knots of enlarged veins, covering a space six inches long by three to four inches wide. The veins are movable under the skin.

The ulcer was directed to be poulticed two or three days, and then dressed with salicylic ointment.

April 15th.—The area of the enlarged veins was marked with nitrate of silver, that it may be readily defined after the application of an Esmarch's bandage.

April 16th.—The patient was etherized. Esmarch's bandage was applied around the limb, from the toes to a space three or four inches above the knee. An incision was then made longitudinally over the mass of enlarged veins, and by careful dissection the veins

were fully exposed. They were tied above and below, and the included portions were excised. There was but a slight oozing of blood after the removal of the compression from the thigh. The wound was closed with numerous fine silk sutures. The operation was performed under carbolic spray, and Lister's dressings were applied.

April 17th.—Patient complaining of some pain in the limb. Temperature in the morning, 99°; in the evening, 100°. Dressings were not disturbed.

April 18th.—Temperature in the morning, 104°. Considerable pain in the leg. The internal saphena vein along the thigh, and the surrounding tissues, are inflamed. Removed the dressings. The wound looks well, but the skin of the leg is very red. There is a serous discharge from the upper end of the wound. The alternate sutures were removed. The wound was directed to be dressed with salicylic ointment spread on lint, and over this a roller bandage. For the phlebitis on the thigh, a blister ten by two inches was directed to be applied over the course of the inflamed vein. Ten grains of sulphate of quinine were directed to be given immediately. Temperature in the evening, 104°.

April 19th.—Temperature in the morning, 103½°. Phlebitis subsiding, but the inflammation about the wound is increasing. The remaining sutures having been removed, the wound gapes throughout its whole extent. Temperature in the evening, 104¼°.

April 20th.—The flaps appear livid and inclined to slough. The discharge is profuse, but not fetid.

April 24th.—The inflammation of the saphena vein has almost entirely subsided. The inflammation about the wound on the leg is also disappearing. The temperature has steadily fallen since the last date. The outer flap has sloughed; there is also some sloughing of the fascia forming the floor of the wound. There are healthy granulations beneath.

April 26th.—The inner flap has lost its vitality, leaving a sloughy surface as large as a man's hand.

May 3d.—The old ulcer on the lower part of the leg is almost healed. The sore left by the sloughing of the flaps is beginning to contract. Adhesive straps were directed to be applied, to approximate the edges.

June 2d.—The strapping has rapidly reduced the size of the sore. From time to time since the operation it has been necessary to evacuate abscesses, and to lay open sinuses in the popliteal space and on the posterior aspect of the thigh, the sinuses having been formed by sloughing of the subcutaneous cellular tissue. This morning the thermometer indicated an unusual rise of temperature. Another abscess in the popliteal space is found to be the cause.

June 9th.—The sore does not make much progress towards healing. Directed the strapping to be discontinued, and the sore to be covered with cloths wet with liq. sodæ chlorinat., diluted with eight parts of water.

July 1st.—The temperature has approached its normal degree. The healing process is advancing, and the sore is now reduced to about half an inch in width. The patient is able to sit up. The strapping of the limb has been resumed.

August 4th.—Since the last report the healing process has steadily advanced, and to-day the patient was discharged cured.

CASE II.—James Bracken, hostler, *ætat.* 54; admitted to the hospital August 28, 1877.

A year ago the patient first noticed that the veins in his left leg were enlarged. Since last Christmas the same leg has several times been covered with an eczematous eruption. The frequent occurrence of

swelling, pain and a sense of heaviness in the leg, would as often oblige the patient to stop work and rest for a few days.

On admission, his left leg was slightly swollen, and the skin red and scaly. Numerous enlarged and varicose veins were found closely adherent to the adjacent tissues. The internal saphena on the thigh is very tortuous, and its coats greatly hypertrophied.

A lotion of acetate of lead dissolved in water, ʒj. to Oij., was directed to be applied to the limb; the patient to remain in bed.

Sept. 6th.—The eczema has greatly improved. To-day the patient was etherized, and five pins were introduced beneath the saphena vein, at intervals along that part of its course which lies above the knee. Small india-rubber bands were twisted over the ends of the pins so as to make elastic pressure upon the vein.

Sept. 13th.—No unfavorable signs have appeared about the seat of the operation. Removed one of the pins to-day.

Sept. 16th.—Two additional pins were removed yesterday and the day before. To-day the two remaining pins, viz., the one nearest to the groin and the one nearest the knee, were withdrawn. The operation has had the desired effect of occluding the vein above the knee. The direct channel to the general circulation being thus cut off, the danger of embolism from an operation on the veins of the leg is reduced to the minimum.

Sept. 23d.—Thorp's multiple cautery, heated to a red heat, was applied over the internal saphena vein at two places on the side of the knee, where the vein was very large and tortuous, the iron being allowed to burn its way into the vein. The sensibility of the part had previously been blunted with ether spray.

Sept. 29th.—The most prominent portions of the varicose veins on the inner side of the leg were punctured at twenty points with a single cauterizing needle heated to a red heat. Ice-water dressings were subsequently applied. No undue inflammation followed the operation.

Oct. 11th.—The knots of veins on the anterior and external side of the leg were treated in a similar manner, and with like favorable results.

Oct. 20th.—Discharged cured.

The radical treatment of varicose veins, by any of the means employed by surgeons, is attended with some danger to the life of the patient. And on this account the palliative treatment, by well regulated and uniform pressure, is to be preferred in the great majority of cases.

But in aggravated cases of the disease, rendering the patient unable to earn his living or to support his family, the radical treatment becomes necessary. And in selecting the means of obliterating the diseased veins, we should always aim to accomplish the object in such a manner as to reduce the danger to its lowest degree. The remarkable absence of unfavorable symptoms in the second case herewith reported, would seem to indicate the elastic ligatures and the cauterizing needles as worthy of further trials in the treatment of this troublesome disease.

BRIGHT'S DISEASE AND RESINA COPAIBA.—A case of Bright's disease showing the remarkable diuretic effects of *resina copaiiba* is reported in the *British Medical Journal* for November 9th. Fifteen grains thrice daily caused the amount of urine passed to increase, in twenty-four hours, from f. ʒ xxxv. to f. ʒ cxxxix.

CONGENITAL MALFORMATION OF TRICUSPID VALVE; LESIONS OF ALL FOUR VALVULAR ORIFICES—SURVIVAL FOR TWENTY YEARS, WITH FEW HEART-SYMPTOMS DURING LIFE.

By ALFRED LUDLOW CARROLL, M.D.,

UNIVERSITY OF NEW YORK.

On the 21st of May, 1878, I was called in consultation by Dr. Arnoux, of West New Brighton, to examine Mrs. V. D., aged 20, who had, within a few days, been attacked with cardiac disturbance of an alarming nature.

I learned from Dr. Arnoux that he had attended the patient in her first confinement, a natural labor, nineteen months previously; and again, about three weeks before our present visit, for a remittent fever, from which she had recovered after a brief illness. On neither of these occasions had there been any symptoms to direct his attention particularly to the heart. She was said to have suffered much from rheumatic muscular pains, but there was no history of acute rheumatism. The existing seizure had been sudden in its access, with much prostration, rapidly increasing dyspnoea, and frequent faintings.

Her aspect was of waxen pallor; pulse rapid, feeble, compressible, and irregular; skin cool. Frequent paroxysms of orthopnoea: the "ladder-like" Cheyne-Stokes respiration typically marked. Feet and ankles slightly oedematous; some ascitic accumulation; liver and spleen enlarged.

The apex-beat of the heart was about two and a half inches to the left of the nipple-line; area of cardiac dulness greatly increased. On auscultation, there was a rasping systolic bruit, loudest towards the apex; the aortic second sound very feeble, and accompanied by a brief, faint murmur; over the pulmonary artery a distinct systolic sound could be heard, and a similar but softer blowing could be detected over the right ventricles. Struck by the apparent signs of congenital malformation, I made further inquiry of the patient's mother, and learned that during infancy and early childhood several physicians had said that her heart was affected, and that she "would never live to grow up;" but that, at the age of about sixteen, she became stronger, gained flesh, and was able to exercise without discomfort.

With such extensive lesions and manifest rapid dilatation of the heart, the prognosis was, of course, hopeless; palliation of the more distressing symptoms during the few remaining days of life being the utmost that we could expect. Under the influence of digitalis and belladonna, with diffusible stimulants, great relief was afforded for a few days. The improvement, however, was but transient, and she rapidly sank, hydropericardium supervening, and death by syncope occurring on the 4th of June.

Sectio cadaveris, made June 5, 1878, permission to examine the heart alone having been obtained: Body fairly nourished; rigor mortis not well marked; abdomen distended. On raising the sternum the pericardium was seen occupying the entire space between the sternal ends of the ribs. It contained about ten fluid ounces of serum; no signs of active pericarditis. The heart itself was more than double the normal size. All the cardiac cavities were filled with soft black coagula; their walls thin and pale; a small ante-mortem clot in right ventricle. Fossa ovalis normal. Pulmonary orifice narrowed, barely admitting the tip of the finger. The tricuspid opening

presented a single apron-like valve, attached to the anterior half of the circumference of the orifice, the posterior half of which was a simple cartilaginous ridge, destitute of any rudiments of cusps. The aortic valves were insufficient and devoid of corpora arantii. The mitral cusps were loaded with warty vegetations, and their edges thickly fringed. The "undefended space" was thin, but intact. Pulmonary artery small; aorta flaccid; great vessels otherwise normal. The lungs were not removed nor incised; they were small, and their surface pale. The diaphragm was bulged upward by ascitic fluid.

I do not recollect any recorded instance of a similar tricuspid malformation, which, regarded as an early arrest of development, would seem to have been rather the cause than the consequence of the pulmonary stenosis. Obstruction of the pulmonary orifice is undoubtedly the commonest of congenital lesions, and in numerous examples has naturally entailed permanent potency of the foramen ovale or solution of continuity in the interventricular septum; but in the present case it appears probable that the fetal insufficiency of the tricuspid, greatly reducing the ventricular pressure, permitted the pulmonic opening to retain an infantile calibre. Of the lesions in the left heart, the aortic was presumably congenital, the mitral acquired, though evidently of long-past date. Aside from the pathological rarity of the case, it is matter for wonder that the patient should have lived as long as she did with a heart so grievously crippled, and that, too, without marked cardiac symptoms for several years. It is likely that the malarial anæmia and hepatic engorgement were the immediate causes of the rapid failure and dilatation of the heart.

NEW BRIGHTON, N. Y.

Reports of Hospitals.

THE PHILADELPHIA HOSPITAL, PHILADELPHIA.

SERVICE OF FRANK F. MAURY, M.D.,

VISITING-SURGEON TO THE HOSPITAL.

(Reported for THE MEDICAL RECORD.)

LUMBAR COLOTOMY FOR STRICTURE OF THE RECTUM DUE TO SCIRRHUS.

—, æt. 43, has enjoyed fair health until within the past fifteen years; does not know of any local injury to the parts; has not passed any foreign body by stool, and has never injured herself with a syringe, etc.; was never troubled with constipation; has been operated upon for internal hemorrhoids; has suffered for the last two years from disease of the uterus; during this period there has been alternate constipation and diarrhœa. The pain following defecation has quite frequently lasted until the next stool. During the past two months there have been constant shooting pains in the neighborhood of the rectum. Her passages vary from two to eighteen a day; they are small and slimy, and frequently contain lumps of hardened feces; now and then the stools are wire-drawn. Quite recently a sanious and offensive discharge has accompanied the stools; now and then there has been great pain during micturition. The woman often has fever in the afternoon, and has lost altogether some forty-five pounds of flesh. She has been in the habit of taking over $\frac{f}{3}$ i. of laudanum daily to quiet the pain.

In commenting upon the case, preliminary to operation, Dr. Maury said: "The operation of colotomy was first performed by Littre, in the year 1710. He opened the sigmoid flexure in the left iliac region. In 1776, Pillore, a surgeon of Rouen, opened the cæcum in the right iliac region. In 1796, M. Callisen proposed an operation upon the left umbilical region, the incision to be made vertically; but he never carried out his idea. The next surgeon to attempt the operation was Finé, of Geneva, who, in 1797, opened the transverse colon in the umbilical region. So much for the pioneers in the field.

"Very little thought was given to the matter, however, until the time of Amussat, who, in the year 1830, published a treatise on 'The Possibility of Establishing an Artificial Anus in the Lumbar Region.' Though the fact is contested, it is generally believed that Amussat did, in reality, perform his operation upon the celebrated Broussais, whom he was treating for a cancerous affection of the rectum. Of all the operations for colotomy, that of Amussat is generally conceded to be the best.

"The conditions for whose relief the operation may be performed are the following, viz.: 1st. To relieve a distended bowel when an otherwise insurmountable obstacle exists in the rectum and sigmoid flexure. 2d. To remove or mitigate very intense pain caused by the passage of fecal matter over a cancerous surface, or when the feces pass into the male bladder through a perforation in the gut, or when motions pass into the vagina, causing a perpetual incontinence of feces. 3d. To relieve or cure an otherwise incurable stricture and ulcer of the rectum. (See Allingham, St. Thomas's Hospital Reports for 1870.)

"Before beginning to operate, it is in all instances necessary to make a mark on the skin over the course of the incision. The descending colon is always normally situated half an inch posterior to the centre of the crest of the ileum—the centre of the crest of the ileum being a point midway between the anterior superior and posterior superior spinous processes of the ileum. A line, four inches in length, should therefore be drawn midway between the last rib and the crest of the ileum. The centre of the incision or line should correspond with a spot half an inch posterior to the centre of the crest of the ileum.

"The patient should be placed upon a hard couch, in a prone position, with a slight inclination to the right side; a hard pillow should be fixed under the left side, so as to render the loins tense. The operator should always stand in front of the patient.

"The incision should be transverse, or downwards and forwards, as recommended by Bryant. The cut should be of the same length all the way down, otherwise the operator finds himself working in a round pit, when he needs all the room he can get.

"In most cases it will be easy to distinguish the gut by the longitudinal bands of muscle, by the hardened feces, and by its greenish color.

"After the intestine has been found, it should be drawn out, and an incision made in it about an inch long. The edges of the incision should be stitched to the edges of the external wound. In stitching these parts together a silk suture will be found to be better than a wire suture. The sutures should be passed before the gut is opened, so as to prevent any of the feces escaping into the wound or abdominal cavity.

"After the sutures have been secured, the wound should be covered with oiled lint, and over this oakum should be laid; a sedative should then be administered, and the patient kept quiet in the recumbent position.

"The sutures may be withdrawn on or after the fifth day. To protect the clothes of the patient from the constant fecal discharges, an india-rubber cap may be worn; or, what is better, simply a folded napkin applied.

"The morbid conditions which it is desired to remedy by performing this operation to-day are the rectal stricture and the constant racking pain to which the woman is a victim. The stricture is, no doubt, caused by some carcinomatous growth, which will not get well. The operation is by no means an easy one, being attended by not a few dangers and difficulties.

"Dr. Allingham, of St. Thomas's Hospital, who has published a paper on the subject in the St. Thomas's Hospital Reports, has performed the operation some fifty times in all, and has made over fifty dissections.

"As he has shown, there is great danger of the patient's dying on the table from shock, and also considerable danger of peritonitis. In some cases there is so much fat in the parietes and omentum, that it is really quite difficult to reach the colon."

The woman being placed in the proper position, and being thoroughly under the influence of the anæsthetic, Dr. Muiry proceeded to make the incision, standing well in front of the patient. The assistants had first, however, painted with iodine on the skin of the left side, a line four inches long, and midway between the last rib and the crest of the ileum.

The operator began his incision as near to the spine as possible, saying that the nearer the incision is to the spine, the less danger is there of injuring the peritoneum. In placing a patient on the belly, while under the influence of an anæsthetic, Dr. Maury had occasion to say that one must needs be very careful that the arms are extended, and do not in any way interfere with the proper expansion of the chest.

The first steps of the operation were retarded by the enormous quantity of adipose tissue present. The operator first exposed the quadratus lumborum muscle, and penetrating the deeper tissues, finally reached the recti spine mass. There was, fortunately, but little bleeding up to this point. The lumbar fascia was then brought to view, and divided layer after layer. Here, one of the smaller vessels supplying the part sprang a leak, and was promptly ligated.

Coming upon something which seemed to be intestine, it was hooked up, but turned out to be nothing more than a mass of omental fat. When the gut was finally encountered, it was transfixed with a needle and tacked up well to the lips of the external wound. After the sutures had been secured, an incision about an inch in length was made between the lines of the sutures.

The patient reacted well from the operation, there being no symptoms whatsoever, either of shock or of peritonitis. After the operation, and during recovery, the woman was cut down to a daily quantity of laudanum not exceeding fʒi.

She is not yet out of bed entirely, but has been brought before the class upon several occasions, and seems to be making a most excellent recovery.

The operating surgeon was assisted by Drs. John H. Brinton, John Packard, and J. William White, members of the surgical staff of the house.

LAPARO-ELYTROMY was performed by Thos. Whiteside Hime, B.A., M.B., lecturer to Sheffield School of Medicine, on July 14th of this year. This is, probably, the first performance of the operation in Europe since its revival by Dr. Thomas in America.

Progress of Medical Science.

A NEW POINT OF ORIGIN FOR THE OPTIC NERVE.—Dr. Stilling, of Cassel, asserts that the opinion hitherto held, that the fibres of the tractus opticus have absolutely no connection with the elements of the crus cerebri, is not correct. According to him, a considerable portion of the opticus fibres spring from a large nucleus situated in the foot of the pedunculus cerebri, beneath the substantia nigra. This nucleus has an almond-shaped outline both on vertical and horizontal sections, hence it would not be inappropriate to call it the nucleus amygdaliformis. The bands of fibres entering it from the tractus opticus, in order to reach it, must diverge sharply from their original direction, so as to form an arch. It is probable from the position, size, etc., of this nucleus, that its function is to preside over reflex excitations.—*Centralblatt für die Med. Wissen.*, No. 22, 1878.

CARBOLIZED JUTE is now being used in antiseptic dressings in the place of the Lister gauze. The following is the formula of Dr. Münnich, for its preparation:

Carbolic acid crys.,	50.0 grams	ʒ iss.
Resin	200.0	"	ʒ viiss.
Glycerine	250.0	"	vijj.
Alcohol	550.0	"	xviij.

The resin is mixed with the greater part of the alcohol and dissolved by the aid of heat; after cooling, the carbolic acid is added, having been previously mixed with the rest of the alcohol. After a few minutes add the glycerine. The jute is thoroughly saturated with this mixture, and dried. The addition of 50 grms. (ʒ iss.) of stearin will make the jute more flossy, but it takes longer to dry.—*Dr. Little, in Am. Clin. Lectures*, Vol. III., No. 11.

THUJA OCCIDENTALIS IN EPITHELIOMA.—Dr. John B. Rice, in the *Michigan Medical News* for Dec. 10, 1878, reports a case of supposed epithelioma of the inferior maxilla, of four months' existence, with tumefaction of the submaxillary and sublingual glands. The patient was a man 72 years of age. The ulceration continued to extend in spite of the various modes of treatment adopted. He was put on fourteen drachms of the tincture of thuja occidentalis (*arbor vitæ*) daily, made from the fresh leaves. In addition, he took five grains of the tart. of iron and potassa, one grain of quinia, and one fortieth of a grain of arsenious acid. Under the above treatment the ulcer gradually assumed a more healthy appearance. The tumefaction of the glands diminished, and after four months perfect recovery took place.

NECROSIS WITHOUT SUPPURATION.—William Colles, M.D., in the *Dublin Journal of Medical Sciences* for December, 1878, reports the following case:

"F., aged 15, healthy, was thrown from a carriage and received some bruises on the face; also there was a slight transverse wound, about one-fourth of an inch, at the ulnar side of the left wrist close to the joint. Through this opening projected a small piece of very rough bone, which was considered to be the lower end of the ulna broken off and projecting. It could not be restored or retained in position. Two days later she was put under the influence of chloroform, but it was still found impossible to restore the natural form of the limb. It was therefore determined to remove the projecting piece. With this view the piece was caught in a forceps, and a direc-

tor passed behind it. It was found that the latter instrument could be easily passed for a considerable distance in all directions without obstruction from ligamentous or other attachments. On bending the hand backwards, and pressing the director inwards, there slipped out a portion of bone two inches long. On examining the forearm, the bones seemed quite naturally in their position, but perhaps slightly larger than those of the opposite limb. On examining the bone extruded, it was much smaller than would be expected in a person of her age; it was quite devoid of periosteum; no cartilage or epiphysary end, but a small rough deposit of new bone; the upper end irregular, jagged, but in no part did it present any appearance of its having been acted on by living parts; and on section—which was difficult, from the dryness and friability of the bone—the medullary cavity was the same as in ordinary section of bones.

"On further inquiry it was found that about eight or ten years ago the patient fell and received what was called a sallyswitch fracture of both bones; this was treated by splints and rest; she recovered with perfect use of the limb, but there was a slight thickening of the bone.

"That this was a case of necrosis there can be no doubt; and if it was the result of injury, it must have been of only two days' duration, which is scarcely possible, for the bone to die, to lose its periosteum, cartilage, and epiphysary end, and for a new case to be formed around the dead bone. Hence it was more probably the result of the fracture received so many years ago."

ON THE USE OF PYROGALLIC ACID IN INTERNAL HEMORRHAGES.—In the *Dublin Journal of Medical Sciences* for December, 1878, Dr. Vesey advocates the use of pyrogallie acid in hemorrhage in phthisis in the hemorrhagic diathesis and from the intestines. He gives it in a one-grain dose, repeated every hour.

He claims for it the following advantages: the dose is small; it does not derange the stomach; it does not cause vomiting, as iron and ergot mixtures sometimes do; it is easily taken, and has no disagreeable after-taste. It appears to be more rapid and certain than other remedies.

A spirit solution of definite strength affords a convenient and ready method of administration. It is readily soluble in water or spirits.

A FATAL CASE OF RAILWAY SPINE.—At a recent meeting of the Medical Society of the College of Physicians in Ireland (*British Medical Journal*, Nov. 30, 1878), Dr. McSweeney detailed at length the particulars of the case of a young unmarried lady, who had been severely shaken exactly six weeks before her death in a collision between two trains on the Kingstown and Dulkey Railway on February 27, 1878. Unfortunately, a post-mortem examination was not permitted. In this patient, the remote sequelæ were more noticeable than the immediate effects, and this agrees with what has been observed by others as to the results of that form of "shock" which is consequent on a railway collision. Wasting and epileptiform "fits" were marked symptoms about the end of the illness. The general muscular atrophy was very considerable; so much so, that the patient presented, towards the close of her life, an extremely wasted appearance. The "fits" ushered in the final event. The progressive muscular atrophy was due, doubtless—as possibly was also the quick pulse—to some morbid condition of the sympathetic ganglia; whilst the convulsive symptoms would perhaps indicate ultimate extensive degeneration of the spinal cord,

following upon the original "jar" or "shock" to the organ. Suspicions (sometimes, doubtless, well founded) are often entertained that patients "linger" after railway accidents, and even that death, when it occurs, is due to some cause other than the collision. The following physical facts, however, were to be observed in this case: *a.* Vaso-motor paralysis, indicated by flushings and injected conjunctivæ; *b.* An affection of hearing, denoted by the effect produced by street noises; *c.* Disturbed nutrition, evidenced by wasting; *d.* Certain neuroses, *i. e.*, hysteria and epileptiform convulsions; *e.* Quick pulse, which is almost constant in railway injuries; *f.* Change of character, sleeplessness, and constipation.

COMPENSATORY EMPHYSEMA IN ACUTE THORACIC DISEASES.—Dr. Reuben J. Harvey has endeavored to disprove the idea that the peculiar condition of resonance, sometimes amounting to tympany, met with in the course of certain acute thoracic diseases (pneumonia, pleural effusion, etc.), can be due, as held by some, to the development of compensatory emphysema. The fact being established that the distending force acting upon the lung in inspiration can never be greater than fifteen pounds to the square inch, it was argued that the one essential condition for the production of compensatory emphysema is that a portion of lung should have to expand into an abnormally large space—too large, in fact, for its natural expansibility. Such a state of things is met with in certain conditions of pleural adhesions; but, in the case in question, this condition was not present, but, on the contrary, the very reverse existed: the unaffected portion of lung occupied a very much smaller space than usual, and was often found post-mortem collapsed to its normal undistended volume. The views put forward in modern text-books—as, for example, those by Guttman and Gee—were shown to be in accordance with these anatomical conditions. According to them, diminished tension of the pulmonary parenchyma is a source of tympany; and this, and not the reverse condition of normal distention, is the cause of the phenomenon in question. According to Guttman, the normal chest percussion-sound is due to three factors, *viz.*: vibration of the chest walls, vibration of the air in the lungs, and vibration of the tense pulmonary parenchyma; and it is owing to the musical interference of these factors that a tympanitic note does not exist. A lung taken from the body, and percussed in its collapsed condition, gives a tympanitic note; but, if distended to its normal intrathoracic volume, it gives a non-tympanitic sound. The disappearance of the tympany is due to the new factor introduced by rendering the parenchyma sufficiently tense to be itself a source of vibration; or, in the reverse case, when the tension is diminished, owing to a large hepatized globe or a pleural effusion, a cause of interference is lost, and tympany is developed.

GASTRO-ELYTROTOMY.—A very interesting historical account of this operation, by Henry J. Garrigues, M.D., has been reprinted in pamphlet form from the *New York Medical Journal*. It was first proposed by Joerg in 1806, but his idea was an incision in the median line involving the peritoneum. In 1820, Ritgen, profiting by Joerg's suggestion, and improving on it, performed the operation by a lateral incision above Poupart's ligament and elevating the peritoneum. He incised the vagina, however, instead of tearing it, and the operation was abandoned, a living child being delivered by Cæsarean section. From 1823 to 1844 Baudelocque, apparently ignorant of

his predecessors, championed this operation or some of his numerous proposed modifications of it, and performed it in two cases unsuccessfully. From this time it was forgotten, or mentioned only to be deprecated by the authorities on obstetrics, until 1870, when Dr. T. G. Thomas performed it, and delivered a living child. Dr. Thomas has since operated once, and Dr. Skene, of Brooklyn, three times, making in all five cases; of these, three of the mothers are still alive, and four living children were delivered; the fifth child was dead before the operation was undertaken, and the two women who succumbed were in *articulo mortis*. The necessity of tearing the vagina instead of cutting it is strongly insisted upon, as troublesome and even dangerous bleeding from the vaginal plexus is thus avoided. The operation cannot be repeated upon the same side, as it would be impossible to raise the peritoneum and lift the vagina. When the head is wedged in the pelvis so that it cannot be pushed up, the incision of the vagina becomes impossible, and the operation is contra-indicated. The obstruction offered by the presence of a solid tumor in the vagina or uterus, or by atresia or coarctation of the vagina, may also be a sufficient contra-indication. Dr. Garrigues's conclusions are: 1. Gastro-elytrotomy ought, when possible, to be performed instead of Caesarean section in all cases; and instead of operations by which the fœtus is broken up when these would be particularly difficult, especially when the smallest diameter of the pelvis measures two inches and a half or less. 2. It does not require exceptional skill, or rare instruments. It is, indeed, less difficult than ovariotomy and herniotomy. 3. Five assistants are desirable, and four indispensable, in order to carry out Thomas's plan.

TREATMENT OF SCROFULOSIS BY TAYUYA.—Starting from the idea that scrofula is allied to syphilis as well as to tuberculosis, Dr. Alpagonorello was led to try in the first-named disease the tincture of tayuya, which has been employed with success by Dr. Faroani in the treatment of syphilis. The results so far have been very satisfactory. It is administered internally in doses of from two to ten drops a day in several chronic cases of hypertrophied and suppurating glands, employing it at the same time externally as a lotion in the proportion of four parts of the tincture to 200 of water. Within a few weeks the wounds had healed, and the general health of the patients had greatly improved. The remedy deserves further trial, especially as it possesses a great advantage over cod-liver oil in having no unpleasant taste or smell.—*Allg. Med. Cent. Zeit.*, Nov. 2, 1878.

ON THE EMPLOYMENT OF LAMINARIA DIGITATA IN CATHETERISM OF THE LACRYMAL PASSAGES.—Dr. Rousseau recommends the use of a wedge of laminaria digitata in place of the pointed stylet usually employed to dilate the punctum lacrymale previous to catheterism. The use of this stylet is painful, and, as a rule, alarming to the patient. He shapes with a knife a small wedge of laminaria, about one-third of an inch in length, pointing it sharply at one end. This sharp end is easily introduced into the punctum, and at the end of five or six minutes the wedge is swollen by the imbibition of tears, and the punctum sufficiently dilated to allow of the passage of any desired instrument.—*Jour. de Méd. de Bordeaux*, Sept. 7, 1878.

RHEUMATISMUS ACUTUS DIAPHRAGMATICUS.—The diagnosis of a rheumatic or neuralgic affection of the diaphragm can rarely be made with anything like

certainty; but in the following case, which occurred in the Vienna General Hospital, the clinical history was thought to admit of no other interpretation. The patient—a strong, muscular butcher, 27 years of age—was seized on the morning of his admission to the hospital with exceedingly violent pains, radiating from the pit of the stomach to the back. The respiration was quick, short, and superficial, and purely thoracic; the abdominal movements which attend contraction of the diaphragm being almost entirely wanting. The face was congested, but there was no febrile movement. The patient, though a strong man, seemed to be entirely overcome by his suffering. The examination of the thoracic organs revealed nothing abnormal. A hypodermic injection of morphine relieved the pain at once, and produced a quiet sleep. On the following morning the patient complained of pains in the right scapular region, but the respiration was not interfered with. A careful objective examination again gave negative results. An injection of morphine at the seat of pain proved as promptly efficacious as on the preceding day. On the third day the patient was discharged entirely cured.—*Bericht der k. k. Rudolph-Stiftung in Wien*, 1877.

DEVELOPMENT OF AORTIC INSUFFICIENCY IN A CASE OF ACUTE RHEUMATISM TREATED BY SALICYLIC ACID.—Dr. Mader, of Vienna, reports this case as the first occurring in his experience, in which a valvular affection of the heart was developed in the course of an attack of acute rheumatism treated by salicylic acid. The patient, a waiter, 25 years of age, was admitted into the Vienna General Hospital on April 25th with a history of having suffered for four days from fever, pains in the joints, and a stitch in the side. There was no swelling of the joints, and the heart-sounds were normal. On the 27th there was distinct swelling of the joints, and the patient was ordered 75 grs. of salicylic acid per diem. On the 29th the articular swelling had diminished, and the daily dose of the acid was reduced to 60 grs. On May 3d the improvement was so great that the acid was stopped. On the 5th of May it was noticed, for the first time, that the heart's impulse was heaving when the patient lay on the left side; and an examination then revealed a distinct, blowing, diastolic murmur at the aortic opening, and a muffled sound in the cruralis. It was impossible to say exactly when the endocarditis revealed by these physical signs had begun; but it was, at all events, certain that no murmurs existed at the time the salicylic treatment was initiated.—*Bericht der Rudolph-Stiftung in Wien*, 1877.

COLCHICINE INJECTIONS IN ISCHIAS.—In the cases of two girls suffering from sciatica that had already become somewhat chronic, Dr. Mader, of Vienna, made repeated trials of the injections of a one per cent. solution of colchicine, recently recommended so highly by Heizfelder. The injections caused as a rule exceedingly severe pain, followed by swelling and great soreness, which persisted for several days. The patients on a few occasions stated that their old pains were diminished for a short time after the injection (perhaps deadened by the new pains), but on no occasion was a permanent effect obtained.—*Bericht der k. k. Rudolph-Stiftung in Wien*, 1877.

A GOOD TOOTH-PASTE.—B. Creta precip., 16 oz.; pulv. iridis., 4 oz.; pulv. ossis sepiæ, 1 oz.; magnesie carb., 2 oz.; moschi, 4 grs.; essent. bergamot, 2 drachms; ol. cinnam. ver., 2 min.; cochinilla, 3 drachms; syr. simp., q. s. ut. f. past. dent.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, January 18, 1879.

THE CARE OF THE INSANE.

MANY of the annual reports of these institutions have lately been presented to the public. A study of their contents cannot but suggest some uneasy feelings to the taxpayer as well as to the humanitarian. We find that, even in so millennial a spot as Massachusetts, \$3,000,000 were spent in erecting the last two of its four great asylums; and other States are not behind-hand in such large expenditures. It is impossible not to feel that there is some extravagance in thus devoting a million and a half of dollars to the erection of a magnificent edifice, which is subsequently to board one hundred and fifty lunatics at six dollars a week. Still it is not so much the mere expenditure of this money to which there is objection. No one can begrudge the unfortunates anything that may help them. But too often these structures only exhaust the State funds in embalming the aspirations of the architect, and are not especially adapted to the improvement of the insane. Their inmates do not need opportunity to saunter through marble halls half as much as they require the watchful attendance of a physician. And we find that, after the asylum is built, there is generally not enough money to supply the patients with effective care. In many places there is only one physician to three or four hundred patients, and one nurse or keeper to forty or fifty patients. The physicians who are in attendance are either poorly paid, or not paid at all, and only the medical superintendent remains in the institution long enough to become familiar with its workings.

An asylum must be very favorably situated if it have a pathologist connected with it. Yet in insane asylums the mortality is often as great as it is in a regular hospital. The insane are liable to phthisis, and they often develop it without giving any rational signs at first. There are affections of the special senses, of the nervous system, and there are surgical troubles which complicate or cause the insanity. All

these things, as well as the disease itself, call for the attention of skilful men. Therefore we cannot see the propriety of spending a thousand dollars on the landscape garden, and only six hundred on an attending physician—a proportion too often observed. In addition, the construction of these costly asylums perpetuates a system of treatment which may before long be abandoned as unscientific and inefficient. It is not too much to suppose that something better can be devised than the present plan of allowing patients to mope all day in a dreary corridor, and exhilarating them once a week with a dance or a drive. Already an entirely different system is successfully working on the other side of the water.

It is estimated that the average duration of life of a person who becomes insane at the age of thirty is from seventeen to twenty years. His cost to the State during this time, at the lowest estimate, is over three thousand dollars. It is evident, therefore, that the cure of the insane is an important item even from a financial standpoint. It falls especially upon the medical profession to see that the best means are taken to secure this end. And for securing it we not only need less extravagance at first, and ill-judged expenditure or parsimony afterwards, but better regulations in regard to the admission and discharge of patients will have to be adopted. It is well known that the earlier a case of insanity is placed under treatment the better chance there is of recovery. But if a poor and friendless man becomes insane, he is very likely at first to get into a poor-house, a work-house, or a prison, and there remain for a longer or shorter period. At the same time, the asylums themselves are constantly overcrowded, and, in this State at least, the percentage of insane has been increasing at a rate vastly greater than that of the population. There can be little doubt that part of this is due to the abuse and misapplication of this charity in common with that of so many others.

The expenditures for the insane have been very large, and their steady increase seems at times appalling. It is greatly to be hoped that a feeling may be created which will compel a more rational and judicious application of the appropriations for this unfortunate class.

THE STATE MEDICAL SOCIETY.

THE Medical Society of this State consists of two sorts of members: First, those who are elected quadrennially by the county societies to represent and guard their interests, with the title of delegates; and second, those who, having actually served as such for a stipulated period, are elected by the Society permanent members. Both delegates and permanent members, when in attendance at the sessions of the Society, enjoy the same rights and privileges, except that the delegates are in a measure subject to the control of the county societies, and obliged to

act in accordance with the instructions that may be given them. The permanent members are independent in this respect. A good many years ago, however, the permanent members obtained the ascendancy, and enacted a by-law which restricted certain important offices to their own members, and by their influence, not sanctioned by law, kept almost constant control of the higher offices of the Society. This power was so well consolidated that it has been asserted that the presiding officer could determine who his successors should be for several years after. The first attempt to break this monopoly was made in 1877, by the then president, Dr. Squibb, who, in his opening address, recommended that the by-law which gave the presiding officer the power to appoint the nominating committee, should be changed in such a way that this power should accrue to the Society itself. The special committee to whom the president's address was referred, reported adversely concerning this recommendation, but the Society, by the requisite two-thirds vote, adopted it. (*Trans.*, 1877, p. 41.) The next step was the report by Dr. Hutchin (*Trans.*, 1878, p. 53), which clearly exhibited the impropriety and illegality of the by-law restricting certain offices to permanent members. This by-law, although disregarded for the last year or two, still remains un repealed.

The renewed importance that this action of the State Society confers on the office of delegate is not to be overlooked, and our satisfaction is only tempered by the regret that these first steps toward reform were not taken by the members from our own county. While thus offering words of commendation we must at the same time draw attention to one or two matters that still need correction. The functions of the Society are of a two-fold character, scientific and legislative. The presiding officer usually makes it his special duty to see that the Society does not suffer as regards the former, and as a consequence there is always a full supply, in fact, a superabundance of literary offerings—brain-food in plenty. As regards the latter, it must be remembered that the whole medical policy of the State is shaped by the action of the Society, and that upon its wise action depends in a measure the material welfare of the profession. As a matter of necessity all questions pertaining to this should receive the most careful consideration. This is impossible in full session, unless the points at issue be thoroughly examined in advance by appropriate committees. To do this the committees should have ample time at their disposal, so that all of them, if necessary, may conduct their private deliberations simultaneously. At the last meeting this could not well be done, as one gentleman was a member of two important committees, and another gentleman was a member of three. Of the two hundred members in attendance was it not possible to find a larger number who were able to share this labor?

The second point to which we direct attention is the exhibition of surgical instruments patented by physicians. The Code of Ethics of the American Medical Association, to which the State Society demands the adherence of all physicians under its jurisdiction, declares that it is "derogatory to professional character," . . . "for a physician to hold a patent for any surgical instrument or medicine." At the last meeting several such instruments were openly exhibited in the antechambers of the session-room of the Society. One of these was patented by a physician from Kings County, and another by one who is high in office in one of the societies in the central portion of the State. Lastly, the seats of members were cushioned with the advertisement of still another patented appliance, which, moreover, was highly recommended by a late officer of the State Society itself! Surely, if the patenting of instruments by physicians is proper, the State Society should formally release the members of the county societies from allegiance to this portion of the American code. If, on the other hand, it is improper, the State Society exhibits a shade of inconsistency in permitting the exhibition referred to within the apartments presumably under its control. If abuses and loose methods of transacting business are again to be a feature in its management, the State Society will soon lose the respect of the profession, and become the prey of medical politicians, rather than the arena for the display of the highest and best thoughts of medical statesmen.

SOCIAL SCIENCE AND ADULTERATIONS.

THE American Social Science Association held its annual meeting at Boston last week. As this science is a very elastic department of human knowledge, the yearly assembling of the Society furnishes excuse for papers on a very wide range of topics. Consequently it happened that some contributions of interest to the medical profession were included. Bearing in this direction was an essay by the Secretary on the evils of ill-constructed tenement-houses and other buildings, in which the people live, work, or are educated. And New York was asserted to head the list of cities whose poor are badly housed—a fact perhaps not especially new.

A more notable paper was read by Mr. G. T. Angell. It was entitled "Public Health Associations," but treated especially on adulterations. According to Mr. Angell, we are in an extremely bad way. Nearly everything we eat, and most of the things we wear, are adulterated. Our cook, wearing a poisoned dress, puts poisoned food in a poisoned dish, and sends it up to be eaten in a poisoned atmosphere. Our bread, made of potatoes and alum, is covered with butter made from the fat of unknown animals and alive with parasites. We pour our watered milk into adulterated tea and sweeten it with sugar made heavy with iron and corrosive with acid. We shake out red lead

with the Cayenne pepper and spread on chromate of lead with our mustard. Our baking-powders are adulterated with alum and terra alba; the terra alba is mixed with sugar and cream of tartar: sugar is poisoned with tin and iron, while even the tinware is made dangerous with lead. And so on in a toxic round of very depressing proportions.

Now, while all these adulterations probably occur, we have no doubt that most of them are infrequent or innocuous. We imagine that Mr. Angell knew this also, but hoped to create a deeper impression by a massing of his facts. There is, indeed, reform required in this direction, and for a reform we need an alarmist. Therefore, Mr. Angell's facts have their uses, though they need not throw the public into a state of anorexia, as they might well do if taken literally.

As the practical outgrowth of this contribution, a petition was circulated praying for the incorporation of "The Public Health Association of Massachusetts."

HOSPITAL SUNDAY.

A CONFERENCE meeting, composed of the representatives of the leading hospitals, was recently held in this city, to consider the necessary steps for establishing a "Hospital Sunday" for the benefit of such institutions. After a long debate, which, however, was mostly confined to prospective details of a general plan of operation, it was finally determined that a Sunday in each year shall be devoted to a church collection of funds in aid of hospitals, and that the previous Saturday be a day for general collection with the same object among the Israelites and amid the non-church-going public at large.

There does not appear to be any question concerning the ultimate success of this movement, and the great benefit which would necessarily accrue to the various charitable medical institutions. Experiments of making collections upon a certain day have been tried with great success in England, and the popularity of Hospital Sunday in all the churches there is a matter of history. There is no reason why, with proper and consistent management, the movement should not be attended with like results. The very fact that there is to be a "Hospital Sunday" so designated will give a popularity to the movement, will arouse general attention in the right direction, and will be a healthy stimulus for that well-directed charity which always commences at home.

There is no doubt also that while the poor of the hospitals will be the gainers by this movement, that there will be also an opportunity for contributions in many churches which has never been offered before, and which opportunity will be gladly taken advantage of by such congregations. The committee having the matter in charge will doubtless, at no distant time, present a general plan for the collection and distribution of the funds. In regard to the latter point, there will, of course, be a division in accordance with

the percentage of charity patients treated in the different institutions. This would, of course, give no opportunity for unequal or sectarian distribution. It is unnecessary to say that we wish the committee having the matter in charge abundant success.

HUMANITY IN EXECUTIONS.

THE condition of public opinion on matters of humanity seems to be a rather anomalous one. Brutality to the lower animals arouses an indignation which speedily checks it by effective laws. Our dogs and horses live tenderly, and die scientifically. On the other hand, if a man is condemned to die, he is likely to be immured in a cell till he is frenzied or imbecile, and then taken out and barbarously asphyxiated. The question of the right or expediency of capital punishment we need not discuss; but if a man's life is to be legally destroyed, the method should be as little revolting as possible, and not be left to the invention or choice of some conceited and ignorant executioner. This business of choking to death is bad enough, no matter how scientifically it may be done; but when, as in a recent case, there was preventable and stupid blundering, the hangman perpetrates a crime against humanity.

Reviews and Notices of Books.

THE PHYSICIAN'S VISITING-LIST FOR 1879. Philadelphia: Lindsay & Blakiston.

THIS standard visiting-list makes its usual annual visit. For completeness, compactness, and simplicity of arrangement, it is excelled by none in the market.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. By W. S. PLAYFAIR, M.D., F.R.C.P., Professor of Obstetric Medicine in King's College, London, etc. Second American, from Second and Revised English Edition. Edited, with Additions, by ROBERT P. HARRIS, M.D. 8vo, 639 pages, with 182 illustrations. H. C. Lea: Philadelphia. 1878.

To the student we can say that no better work on obstetrics than Playfair's can be found. Pelvic anatomy, ovulo-menstruation, physiology, conception, changes during and the diagnosis of pregnancy, are fully though concisely described. LABOR, its mechanism, its abnormalities, its dystocia, its management, are treated in the soundest and most reliably practical manner; all the advances in the obstetric art, up to the very day of publication, are to be found lucidly recorded in this most valuable work. The same may be said in regard to the pathology and treatment of the puerperal state, which closes the volume. To the practitioner we especially recommend this volume, on account of its wide range of subjects, practical, new, and sound teachings, and comprehensively concise style, making it a *multum in parvo*.

The fact that a second edition appears in less than two years subsequent to the first issue, is in itself a sufficient recommendation of the worth of the book.

Under the present circumstances, this volume needs no extended review from us; but we will simply

point out some of its excellent points, not omitting to designate where improvements might be made.

The anatomy of the pelvis and pelvic organs is lucidly described and well illustrated. Conception and generation, those changes which occur in the ovule and uterus after impregnation, are described in so concise and clear a manner, and so beautifully illustrated, that this rather difficult part of physiology cannot fail to be understood by the student. The same may be said of the anatomy and development of the fœtus. In regard to the non-shortening of the cervix during pregnancy, we are sorry to notice that Dr. Playfair still omits to mention Prof. Isaac E. Taylor's labors on the subject. This is inexcusable, since Dr. James C. Reeves, in reviewing the first edition (see *Amer. Jour. Med. Sci.*, Jan., 1877), called attention to this omission. Pregnancy, its organic changes, diagnosis, abnormalities, and diseases, is very satisfactorily described. Let cerium oxalate be given in gr. x. doses, and greater success will follow its use in the vomiting of pregnancy. Curiously enough no mention is made of the use of atropia or hyoscyamia in this trouble. On page 206, line 9, the word *knee* should be placed between "and" and "position." The mechanism of labor, as described by Dr. Playfair, is eminently simple and practical. Illustrations from Hodge's great work are here introduced to special advantage.

The engraver has not been fortunate with fig. 98, p. 264, since the vertex appears to be in the right occipito-iliac (transverse), instead of the right occipito-sacro-iliac position, as designed.

The author certainly gives very excellent rules for the management of labor.

In the management of the perinæum during the delivery of the head, we again notice the absence of the method, so ably advocated by Dr. I. E. Taylor, namely, the retention of the head upon the perinæum during the *absence* of pains—thereby preserving gradual and constant dilatation of the vulva—by pressure upon the fetal forehead with three or four fingers behind the anal orifice, and in front of the coccyx. The importance of delivery of the placenta by *expression* instead of traction upon the cord, receives the fullest attention.

Dr. Uvedale West's views on non-rotation in occipito-posterior positions are here elucidated and accepted (p. 307). The editor adds a very interesting and practical article on *ante-partum* hour-glass contraction of the uterus, or, as he calls it, "tetanoid falciform constriction of the uterus."

Pelvic deformities are described most satisfactorily. Fig. 125, p. 369, shows rather too large dimensions, especially in the inferior diameter, to satisfactorily represent an "adult pelvis retaining its infantile type."

Dystocia from all causes are treated by Dr. Playfair in a most rational and fearless manner. He is not afraid of operations where necessary, excellent rules for which he lays down.

A woodcut illustrative of Barnes's theory of placenta previa would have added to the elucidation of the subject.

Dr. Playfair's chapters on "obstetric operations" are truly excellent. Considering their wealth of illustration, their concise comprehensiveness of details, and the very valuable additions of the editor, we can honestly say that they are the best in the book, and unequalled in any other work of the kind. We are surprised that the editor did not add a figure and description of Dr. Lusk's cephalotribe, which is certainly the equal of Hicks's.

A most excellent formula (Prof. Frankland's) for the preparation of artificial mother's milk is given. The author looks upon that ill-named "puerperal fever" as simply a septicæmia developed during the puerperal condition, whether complicated by metritis or peritonitis, or both, or neither, matters not as to its essential pathology. Every physician should read the views herein set forth, and the rules for treatment therefrom deduced.

HABITUAL DRUNKENNESS, AND INSANE DRUNKARDS.
By JOHN CHARLES BUCKNILL, M.D., London, F.R.S., F.R.C.P. Eng., etc., etc. 12mo, pp. 103. London: Macmillan & Co. 1878.

WITHIN this small volume are brought together various papers and remarks of the author upon the topic which heads this notice. To those interested in the subject of drunkenness his views are well known, no doubt. Dr. Bucknill holds that habitual drunkenness is a vice, is not a disease, although it may produce the latter; being a vice it should be treated as such, by moral influences and proper surroundings, and this moral punishment should be inflicted by the State. He has no faith in the so-called reformation of drunkards; he denounces private inebriate asylums as worse than useless. "The only institution in which I did find good, honest, earnest work being done was the inebriate Reformatory at Philadelphia, in the management of which the idea of curing a disease is steadfastly put on one side." We recommend this little book to all our readers who are interested in such matters as containing much food for careful consideration, since the author's convictions spring from an honest, philosophical, and humane view of the subject.

CONSPECTUS OF ORGANIC MATERIA MEDICA AND PHARMACAL BOTANY. By L. E. SAYRE, Ph.G. Philadelphia: D. G. Brinton. 1879. Pp. 211.

THE work commences with a chart containing all the official drugs of organic origin. They are arranged according to their natural botanical orders, the official names of each substance being followed by the botanical and common name of the plant from which it is derived, together with the habitat, part used, constituents, principal medical properties, dose, and officinal preparations. This is followed by about thirty pages devoted to structural botany. The rest of the book is devoted to the consideration of the characteristics and properties of the individual drugs. The work will prove useful for reference.

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY (88th Anniversary), held at Concord, Concord, N. H.: Republican Press Association. 1878.

THE papers in this volume, though few in number, are good in quality. The president's address calls for no special notice, being general in character. "The Pauper Insane of New Hampshire," by J. P. Bancroft, M.D., of Concord, is a plea for the proper treatment and care of these unfortunates under the supervision of alienists who are directly responsible to the State. The next paper, a "Report on Surgery," by William Child, M.D., of Bath, is too short to be valuable. "Some of the Risks and Responsibilities of the Profession," by E. E. Graves, M.D., of Boscawen, may be read with interest and profit. A judicious argument may be found in "Reasons for Modern Alcoholic Stimulation Examined," against the wholesale and routine use of alcohol in disease, especially fevers, etc. The opinions of a large number of leading practitioners in the United States—Isaac Hays, Alonzo Clark, Flint, Parker, Gross, Ellis, Bowditch, Post, and

others—as to a change in the type of diseases, are to be found herein recorded. D. S. Adams, M.D., of Manchester, follows with an excellent paper on "Carcinoma." Among other things, he says (p. 111): "I am frank in saying that I do not believe that any person, with our present state of knowledge, can distinguish benign from malignant tumors in all cases by microscopic examination alone. The last, though by no means least valuable, paper is from the pen of Dr. L. Duncan Bulkley, of this city, on "The Use of the Solid-Rubber Bandage in the Treatment of Eczema and Chronic Ulcers of the Leg."

Obituary notices appear of the late Professors Alpheus B. Crosby (by J. W. Barstow, M.D.), and Edmund R. Peaslee (by H. T. Hanks, M.D., of this city), and of Albert Smith, M.D., LL.D. (by Henry M. Field, M.D.), one of the lights of the profession in New Hampshire. Three other obituary notices close the volume.

CLINICAL DIAGNOSIS: A Handbook for Students and Practitioners of Medicine. Edited by JAMES FINLAYSON, M.D., Physician and Lecturer in the Glasgow Western Infirmary; Examiner in Clinical Medicine, etc., with eighty-five illustrations. Philadelphia: Henry C. Lea. 1878.

This manual is destined to hold its own among many superior works of its class. Besides the editor, Drs. W. T. Gairdner, Wm. Stevenson, Alex. Robertson, Samson Gemmill, and Joseph Coats, all well-known Scotch physicians, have contributed articles relating to their several specialties. The style of presenting the various methods of making a diagnosis is a model of conciseness and quite suggestive in character. Without any pretence at exhaustiveness, it still can lay claim to being a work of reference of no mean order; at all events, the reader will not be disappointed.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 23, 1878.

DR. FREEMAN J. BUMSTEAD, PRESIDENT, IN THE CHAIR.

THE AID WHICH MEDICAL DIAGNOSIS HAS RECEIVED FROM RECENT DISCOVERIES IN MICROSCOPY.

DR. CHARLES HEITZMAN delivered an interesting lecture upon the above subject.

After prefatory remarks to the effect that the physician who was not familiar with macroscopy and microscopy was very much like the Indian medicine-man who worked without anything to guide his experience, he proceeded to the demonstration of certain points which had been reached, and that enabled him to make diagnoses which, six years ago, were impossible.

He first spoke of

URINARY SEDIMENTS, ESPECIALLY TUBE-CASTS; RECENT RESEARCHES ON THEIR ORIGIN AND VARIETIES; THEIR DIAGNOSTIC AND PROGNOSTIC VALUE.

In order to understand the urinary sediment it was necessary to be familiar with the anatomy of the kidney, and the anatomy of the kidney could not be understood without familiarity with its entire histology.

When that was mastered the study of the urine could be commenced.

The anatomy of the kidney was first considered, and a detailed description given of the structure of the cortical and the pyramidal substance.

There were mainly three kinds of inflammatory processes in the kidney, formerly considered under the general term Bright's disease. He thought, however, that such terms as Bright's disease and Pott's disease were general terms, and should not be used by scientific men.

The inflammatory processes in the kidney were mainly of three kinds: 1. Catarrhal; 2. A more severe form, or croupous; and 3. A still more severe variety, suppurative nephritis.

The catarrhal process consisted essentially in a serous exudation, in which there was desquamation of a certain amount of epithelium that could be seen in the urine. That primary condition could give rise to new connective tissue formed from epithelia, and at last terminate in the small granular kidney. If, therefore, we found in the urine a varying amount of albumen with epithelia of the kidney, recognized by their size, we could determine positively that an inflammatory process of a milder character was going on in the organ; in other words, that the patient was suffering from catarrhal nephritis.

In another series of cases there was present in the urine a varying amount of albumen and tube-casts.

Dr. Heitzman believed that the tube-casts consisted of protein substance, or a modified form of fibrinous or albuminous material. Hence there was no good reason for omitting the term *croupous nephritis*. He then referred to the various theories which had been given regarding the formation of tube-casts: 1. That an exudation took place in the tubules, coagulation occurred, and casts were formed; 2. That the epithelium lining the tubules was transformed into casts; and 3. That the casts were produced by the coagulation of material secreted by the epithelia themselves. The latter was the theory which he adopted.

A brief description of the various kinds of epithelium found in the uriferous tubules was then given: 1. The epithelium of the convoluted tubules, which he thought were separated by a cement substance; 2. The flat epithelium of the loops of Henle; and 3. The cylindrical epithelium in the straight tubules.

In sections of kidney, which were the seat of croupous nephritis, cast material could be seen in the tubules; and of casts there were five varieties:

1. Hyaline casts; 2. Epithelial casts; 3. Blood casts; 4. Fatty casts; and 5. Waxy casts.

There might be a sixth variety, or granular casts.

In ordinary acute croupous nephritis there were found in the urine hyaline and epithelial casts; but if the disease was very severe there might be blood casts.

In the chronic stage of the disease there were found granular casts; and if fat globules were present it was indicative of fatty degeneration of the kidney. Lastly, if waxy casts were found in the urine it was evidence that we had to deal with a waxy degeneration of the kidney.

Dr. Heitzman believed that whenever casts appeared in the urine they indicated severe disease of the kidney, namely, croupous nephritis.

A recent German writer had advanced the opinion that mere hyperæmia of the kidney could give rise to casts, but he doubted the correctness of that opinion.

Not only did casts indicate the stage and the nature

of the disease, but they also indicated the portion of the kidney which was the seat of the disease. In the mildest cases the casts were from the loop tubules and the convoluted tubules of the second order. If the number of casts from the convoluted tubules was considerable, it was known that the cortical substance was chiefly invaded. The mere size of the casts, besides the number and the character of the cast, was indicative of the disease called croupous nephritis. We very often met with casts from the convoluted tubules with stump-like attachment, which indicated that they had also been formed in part in the straight tubules. That was a form of cast which he had not seen described, and indicated the exact situation of the inflammatory process. Based upon these principles, he had been able to make a diagnosis by examination of the urine alone, and had seen his diagnosis proved true by the subsequent history of the cases. As an illustration, the urine of a boy, six years of age, was brought to him for examination. He had suffered from a very slight attack of diphtheria. Three varieties of casts were found in the urine, and the case was set down as one of severe croupous nephritis. The boy died three days after in a convulsion.

There was possibility of recovery from croupous nephritis under the following circumstances: 1. When it occurred in connection with scarlet fever; and 2, when developed in connection with pregnancy, or, as occasionally happened, after delivery. In the first instance recovery was due mainly to the recuperative power possessed by children, and in the second class of cases it was because only one kidney, as a rule, was affected. Perfect recovery in both instances was possible.

With reference to *pus corpuscles* he was able to tell where they came from only when they were mixed with epithelia, which indicated the seat of the disease. If *pus corpuscles* with flat epithelia were found in the urine it was evidence that suppuration existed in the bladder. If the caudate epithelia were present with *pus corpuscles* it was evidence that the pelvis of the kidney was the seat of the suppurative process.

If small epithelial cells were found with *pus corpuscles* it was evidence that the inflammatory action was in the kidney itself.

It was only in acute cystitis that the flat epithelial cells with *pus corpuscles* were found. In chronic cystitis the flat epithelia were absent, and black pigment was found in the *pus corpuscles*.

Again, if *pus corpuscles* with epithelia from the kidney were found in the urine it was evidence that more or less dangerous suppurative process existed in the kidney. If hematoidine crystals were found in the urine it was evidence of chronic morbid process, and if associated with *pus corpuscles*, of a chronic suppurative process.

In the second place, Dr. Heitzman spoke of the

MICROSCOPICAL EXAMINATION OF THE SPUTA, AND ITS VALUE IN THE DIAGNOSIS OF LUNG DISEASE.

The chief elements met in the sputa were mucous corpuscles and *pus corpuscles*. The question arose, What was the difference between a mucous corpuscle and a *pus corpuscle*? The answer was, that the mucous corpuscles were nothing but the protoplasm of the epithelial cells themselves, and were pale and *finely granular bodies*, while the *pus corpuscles* were *coarsely granular bodies*.

Dr. Heitzman believed that Cohnheim was mistaken when he stated that all *pus corpuscles* were migrated white blood corpuscles, for the formation of *pus cor-*

puscles could be traced to the firmer tissue itself. No one would deny that a certain number of *pus corpuscles* were migrated white blood corpuscles, but he did not believe that all of them were produced in that manner.

The lungs normally contained a certain amount of pigment, therefore when *pus-cells* found in the sputa contained pigment granules, it was an indication as to where the *pus-cells* came from. The presence of elastic fibres on the sputa indicated that there was positive destruction of lung-tissue. He might not be able to say what had destroyed the lung tissue, but it could be said with great certainty, if with the fibres there were found certain protoplasmic bodies, that the destruction was due to the formation of a cavity.

Reference was then made to cases in which he had been able to make a diagnosis of serious lung disease by examination of sputa before any evidence of such disease was given by physical signs.

MICROSCOPICAL EXAMINATION OF THE FECES

might furnish valuable aid in diagnosis. We could readily tell whether we had to deal with a shallow inflammatory process, like dysentery, or a more severe disease called ulcerative proctitis; for if shreds of connective tissue were found it indicated the existence of the severe inflammatory process.

Reference was made to one case in which diagnosis of hysteria was made, by finding that a peculiar material, which the patient passed in large quantity, was composed of vegetable remnants unlikely to be taken as an article of food.

In the fourth place Dr. Heitzman spoke of

THE COMPARISON OF THE DIFFERENT TAPPED FLUIDS WITH REGARD TO THEIR FORMED ELEMENTS AND THEIR DIAGNOSTIC VALUE.

In *ascites* the fluid contained, besides a varying quantity of albumen, a varying number of endothelial cells from the peritoneum, and invariably a greater or less number of *pus corpuscles*. The presence of endothelial cells was a diagnostic sign of *ascites*. In fluid drawn from the *cyst of the broad ligament* nothing of the kind could be seen. He thought it well to be careful with reference to regarding Drysdale's corpuscle as positive evidence of the existence of an ovarian tumor.

THE DIAGNOSIS OF TUMORS WITH THE AID OF THE MICROSCOPE.]

was the fifth topic in the Doctor's discourse. There was no doubt the science of microscopy had advanced so far that we were able to tell positively what kind of a tumor we had to deal with. If a few points were kept in mind we could easily determine whether we had to deal with a benign or with a malignant growth. The key to diagnosis was chiefly in the basis substance, whether fibrous, myxomatous, cartilaginous, or bony. The more of the basis substance present the more certain was the tumor benign; the less the basis substance the surer was the tumor malignant. Malignant tumors were of two kinds: 1. The kind belonging altogether to the connective tissue series, and termed sarcoma; and 2, the kind belonging to epithelial formations, and termed cancer. Further, if we saw slight basis substance without epithelial elements, and without alveolar arrangement, we could say that it was a sarcoma; while if we saw epithelia arranged in alveoli, without respect to size or shape, we made the diagnosis of cancer. In the latter case, also, a great deal could always be determined by examination of the connective tissue outside of the epithelium. The more abundant the connective tissue

about the epithelial nests the less malignant was the cancer, while the more numerous the epithelia were, and the less abundant the connective tissue, the more certain we were that the cancer was a malignant one.

Again, there were present in the connective tissue itself a varying number of peculiar shining globular elements which, by recent examiners, had been considered as the product of a kind of inflammatory reaction from irritation of the epithelium. The more crowded those corpuscles were, the worse the cancerous tumor. If we wished to know whether or not the tumor had been thoroughly extirpated, it should be examined about its boundary. If the connective tissue was found provided with only a small number of inflammatory elements so-called, we might be sure that the cancer would return within a very short period of time.

The sixth topic of Dr. Heitzman's lecture was

THE AID FURNISHED BY PUS-CORPUSCLES AND COLORLESS BLOOD-CORPUSCLES IN JUDGING OF THE GENERAL CONSTITUTION — DIAGNOSIS AND PROGNOSIS BASED UPON THE ANATOMY OF PROTOPLASM.

Under this head the lecturer refers to the discovery which he made five years ago, regarding the anatomy of protoplasm, and its presentation before the Society three and two years ago. (See *MEDICAL RECORD*, Vol. XI., p. 322, and Vol. XII., p. 94.) He then claimed that protoplasm of any description invariably contained a net-work of threads and granules, that held in its meshes a fluid, and that the threads and the granules constituted the living matter. Today, more than a dozen of the best microscopists abroad had accepted his discovery, although it had not been recognized in this country. That the reticulum was present, no one had a right to doubt; but that the threads and granules were living matter had as yet not been acknowledged. That it was living matter he had to prove, which he felt himself able to do by the recognition of two well-established facts.

The first property attributed to living matter was *motion*; and the second, *capacity for reproduction of its kind*.

As evidence that this matter was living, was the motion which could be seen in it, and it was enough to establish its reproductive power to know that the granules increased in size and number during the inflammatory process. Transferring the idea to the study of the human body, Dr. Heitzman reasoned that these corpuscles should contain more living matter in the healthy and strong individual than in the broken-down and scrofulous person.

Acting upon that supposition, he began, three years ago, to study pus-corpuscles in the urine in connection with clinical histories, and reached the conclusion that the constitution of the person from whom they came could be determined in that manner. Having settled the question that pus-corpuscles from a healthy person contained an abundance of living matter, an abundance of granules, while those from a debilitated person contained granules which were very small and a very marked net-work, it occurred to him that perhaps by examination of the colorless blood-corpuscles he would be able to tell directly what the constitution of the individual was from whom the blood was taken. So it was, and he had found that when the colorless blood-corpuscles, examined with moderately high power (800 to 1,000 diameters), were found to contain an abundance of granules, it was evidence of a first-class constitution; on the other hand, if only fine granules were seen, and the entire body of the corpuscle was pale, it was

evidence of a poor constitution. He had very often noticed that the number of white blood-corpuscles was considerably increased after a single sleepless night, so much so, that it might be determined whether a man had been kept from his rest or not, by examination of his blood. It could also be determined whether a man was to have acute diseases, or whether he was to suffer from the slow processes of disease incident to a strumous diathesis.

These facts being determined, they might exert a very great influence upon the entire question of life assurance.

Not only that, but they might exert an important influence upon the question of marriage.

To know something of the general condition of our patient was very important. If that could be determined by an examination of a drop of his blood, we had learned much with regard to his future welfare, and a new field was opened worthy of the investigation and study of every physician.

The subject being before the Society for discussion, DR. GILLETTE remarked, with reference to the statement made by Dr. Heitzman, that hyaline casts could not occur in the urine unless a grave inflammatory process was behind them, that he had not been led to attach so much importance to their presence in the urine. He spoke especially with reference to life assurance examinations, and formerly he thought the mere presence of hyaline casts in the urine was sufficient reason for rejecting the applicant. But he had watched several such cases for four years, and no evidence whatever had developed to suggest that the casts had any clinical significance.

He further referred to Charcot, Richardson, Dickin-son, and Ziemssen, who did not attach that importance to hyaline casts in the urine that had been given to them by Dr. Heitzman.

DR. HEITZMAN remarked it was contrary to his own experience that hyaline casts existed in the urine without being due to serious inflammatory process in the kidney.

DR. H. G. PIFFARD remarked that since Dr. Heitzman announced the peculiar construction of protoplasmic cells many had witnessed its demonstration in his laboratory, and had it been referred to a committee of investigation, doubtless more would have been satisfied of the truth of the discovery.

With reference to other matters in the lecture, much that had been said could be readily accepted.

Some points, however, were new, and if true, were of the utmost importance; for example, the assertion that the character of the constitution of a person could be determined by the appearance of the white blood-corpuscles.

With Dr. Heitzman's consent, he moved that a committee of three be appointed by the President to investigate the subject and report to the Society. The motion was adopted.

After remarks by Drs. Elsberg, Weber, and Sell, Dr. J. C. Peters read a memorial on the late Dr. Snelling. The Society then adjourned.

A DIAMOND WEDDING was recently celebrated in the little town of Kollmar, in Holstein, to commemorate the seventy-fifth anniversary of the marriage of two surviving spouses. It appears that two more celebrations of the same sort are expected to take place shortly in the same town. There have been ten diamond weddings there during the last fourteen years.

Correspondence.

THE VITAL STATISTICS OF NEW YORK.

DEATHS vs. BIRTHS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—If the secular press be correct in its summary of the vital statistics of New York for the past year, it reveals a state of affairs worse even than that which has lately called the sympathizing attention of political economists to the alleged decadence of France. 25,729 births against 27,005 deaths leaves an ominous balance on the debit side of the municipal account, even when liberal allowance is made for neglect in recording nativities. And this excess of death-rate over birth-rate has extended through a number of years past, according to the official reports of the Health Department.

It would be difficult to ascertain the number of immigrants who become permanent residents of the city (unless, perhaps, they could be roughly estimated from the naturalization records); but it would be interesting to learn from the Board of Health whether it entertains any theory to explain the increase of population; and also whether, supposing its records to be defective and misleading, despite its legal power to enforce registration, it be worth while to publish a fragmentary list of births which only serves to invalidate all statistical calculations.

I am, sir, yours, etc.,

A PERPLEXED SANITARIAN.

OXALATE OF CERIUM IN CHRONIC COUGH.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I have noticed in several of the current medical periodicals, testimonials as to the efficacy of oxalate of cerium in chronic coughs. I desire, through the medium of your valuable journal, briefly to add my own experience in its use.

My attention was first called to this drug, in the capacity already mentioned, something over a year ago, since which time I have used it in a goodly number of instances, until I have come to regard it as one of the principal remedies in the treatment of this distressing malady.

Coughs resulting from chronic bronchitis, phthisis, and chronic laryngitis, have promptly yielded to this remedy in my hands, after both the internal and external administration of other drugs had signally failed. In giving it to adults, in only one instance have I ever experienced any ill-effects from its use. This was a case very similar to the one reported in the RECORD for December 28, 1878, by Dr. La Roe, of Greenpoint, L. I. On this occasion I used seven grains at first, which produced the narcotic effect he speaks of as following the taking of five grains. I then reduced the quantity to five grains, which quieted the cough without the deleterious effects first produced. When I first began using oxalate of cerium, I produced decided narcotic effects in two instances from the administration of five grains to children of from ten to thirteen years of age.

In prescribing this drug, I invariably direct it to be taken half an hour before rising in the morning; and I may say that, although I have used it frequently, I

have in only one or two instances been disappointed in the effects produced. I give five grains to adults, and diminish the dose, when treating children, in proper ratio, according to age.

FRANK ALLPORT, M.D.

SYCAMORE, ILLINOIS.

A NOVEL VIEW OF THE CREMATION QUESTION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I noticed in No. 422 of your valuable journal a reference to Dr. Gross's views on cremation, as given by that eminent surgeon to a representative of the *Philadelphia Press*. The subject is certainly one of great importance, and the hygienic advantages to be derived from the abolition of interment are certainly great, although perhaps liable to be overrated. But, allow me to speak of another relation which, it seems to me, does not receive due consideration by the medical profession. I am referring to the chemical aspect of this question of cremation.

Taking for granted—for my purpose—that interment is a method of disposing of the dead both disgusting to our educated feeling and dangerous to our health, there remains to be decided another question, viz., whether cremation is really the most economical way of destroying dead bodies. And here chemistry comes in and answers negatively. For cremation could never be introduced into civilized communities without arrangements being made in the various furnaces constructed to burn up all the smoke produced by the combustion of the human body. And this includes the destruction of a constituent of our own as well as of all other vegetable and animal bodies, the supply of which is limited—at least as far as we know. This constituent is *ammonia*. In this combination the various nitrogenous bodies that play such an important part in vegetable and animal life are introduced into the vital circulation, and are also eliminated from it in the same shape. It has been Liebig's greatest achievement to point out and trace through all its stages the circulation of nitrogen and its compounds. The chapters: "*Der Ursprung und die Assimilation des Stickstoffes*" and "*Die Quellen des Ammoniaks und der Salpetersäure*," in his immortal work, "*Die Chemie in ihrer Anwendung auf Agricultur und Physiologie*," are classical, and leave no doubt in the mind of the reader as to the true sources, distribution, and final condition of ammonia and its allies.

Chemistry, therefore, does rightfully claim that not only must cremation of necessity waste and destroy an immense bulk of organized material which is thus abstracted from that portion of the earth's capital that is capable of vitalization, but it also irreparably wastes and destroys ammonia and kindred nitrogenous substances, the sources of which are not as yet fully understood, and the supply of which, for aught we know, is undoubtedly limited.

Ammonia, nitric acid, and principally nitrite of ammonia, are formed from atmospheric air, in consequence of a certain amount of commotion produced in our atmosphere, either mechanically or by some electric or galvanic discharge. *This is the only source of ammonia positively known to us.* Rain and thunderstorms therefore supply to us a chemical combination of elements, the importance of which is recognized more and more every day.

And here we meet with certain public improvements (?), the establishment of which is due to just such misapplied hygiene as may at any time give us the

improvement (?) of cremation. For, by our great system of sewers, that cost millions upon millions of dollars, we are diligently and carefully throwing away, by leading them into the great rivers and the sea, just those valuable nitrogen constituents which we are importing with great cost, under the fashionable form of "guano."

The first one to raise this valid objection to cremation with combustion of smoke was Friedrich Mohr,* the eminent chemist, the greatest living since Liebig died. His warning should be heeded before it is too late; and, although we shall not live to see the ammonia-famine, it will surely come, if the present or the next generation does not reform.

Instead of supplanting interment by cremation, the most rational way would be to cover up all the dead bodies of men and animals alike with quick-lime, and thus preserve their ammonia-compounds for further circulation by using them as fertilizers.

Whether this way of disposing of our dead would meet with the sentimental approbation of humanity in general is, of course, rather doubtful. Very probably only necessity, *i. e.*, the instinct of self-preservation, will at some future time, quite remote from the present, force men to the realization of such extreme measures.

This is the conviction of your correspondent.

GEO. W. RACHEL, M.D.

53 E. 3d St., N. Y.

TINCTURES FROM FLUID EXTRACTS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Is there not a chance for serious accident in dispensing, indiscriminately, tinctures made from fluid extracts and from crude herbs? For instance, a druggist has been furnishing a physician on prescription a tincture of digitalis from the fluid extract, the dose of which, according to the formula given by the manufacturer of the fluid extract, is forty-five to ninety drops, and the druggist should fill the prescription with a tincture made from the herb according to the U. S. D., the dose of which is ten to twenty drops. This would give the tincture from the herb in forty-five to ninety drop doses.

Cannot some step be taken to regulate fluid extracts so as the tinctures made from them will correspond in dose to those made from the crude herbs.

H. PALESTINE, Texas.

[Fluid extracts are all supposed to be of the same strength, one minim corresponding to one grain of the crude material. They of course differ in actual strength depending on the *quality* of the herb employed by different manufacturers. Perhaps the maker of the one referred to was aware that his own production was of inferior quality and knew that it must be given in larger doses to produce the desired effect; besides, the larger the dose, the sooner the bottle will be finished and another one required. We do not know that there is any objection to making tinctures from fluid extracts, but the practice of some apothecaries of dispensing so-called "infusions" made from fluid extracts is wrong, and should be stopped. There is a very decided difference in the *quality* of effect between the watery and alcoholic preparations of digitalis and some other drugs. This pernicious practice is encouraged by the labels which some fluid-extract makers put on their bottles.—Ed.]

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 5 to January 11, 1879.

SEMIG, B. G., 1st Lieut. and Asst. Surgeon. Now on leave of absence, to report in person to the Com'd'g General, Dept. of the South, for assignment to duty. S. O. 7, A. G. O., January 9, 1879.

ROSSON, R. L., 1st Lieut. and Asst. Surgeon. Assigned to duty at Camp Apache, A. T. S. O. 149, Dept. of Arizona, December 23, 1878.

GRAY, C. C., Major and Surgeon. Relieved from duty in Dept. of the Missouri, to proceed to his home, Chester, N. Y., and there await further orders. S. O. 7, A. G. O., January 9, 1879.

BOOKS AND PAMPHLETS RECEIVED.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK.—Dr. A. L. Ranney has been elected Adjunct Professor of Anatomy for this institution.

NEW YORK PATHOLOGICAL SOCIETY.—The following officers have been elected for the ensuing year: President, Dr. E. L. Keyes; Vice-president, Dr. Joseph W. Howe; Secretary, Dr. Geo. F. Shady; Treasurer, Dr. John H. Hinton, and Editor of Transactions, Dr. John C. Peters.

THE PHILADELPHIA SOCIETY FOR ORGANIZING CHARITABLE RELIEF AND SUPPRESSING MENDICANCY intend to extend the sphere of their usefulness so as

* In the scientific monthly. "Gaea," XI., p. 536.

to supervise the dispensary patients. No dispensary physician will be allowed to treat a patient a second time, unless he brings with him a certificate from the ward superintendent of the Society to the effect that he is deserving of medical assistance.

A NEW CHAIR IN THE MEDICAL SCHOOL OF THE UNIVERSITY OF PENNSYLVANIA.—The trustees have just created a chair of "The Anatomy and Surgery of the Joints" in the Medical Department of the University of Pennsylvania. Among a number of candidates, Dr. Charles B. Naucrède, one of the physicians to the Episcopal Hospital, seems to be the one most likely to receive the appointment.

URGING THE METRIC SYSTEM.—The report made by representative Maish, from the Committee on Coinage, Weights and Measures, presents a condensed history of the metric system, and assumes that the first essential thing for the civilized world is to establish at this time a fixed and determined unit of international linear measurement. The committee earnestly recommends the early passage of the House bill introduced at the last session of this Congress to establish the metric system in the post-offices and custom-houses of the United States. The metric system has already been adopted, voluntarily, by the Bureau of Statistics, the Medical Purveyor's Office and Coast Survey, and in some of the bureaux of the Treasury Department computations are made according to this system.

PUBLIC HEALTH.—A special session of the Advisory and Executive Committees of the American Public Health Association was held on January 3d and 4th, at Washington. They advised that Congress create a National Provisional Commission, whose duties should be to investigate the late yellow-fever epidemic, and devise a plan for a national public health organization. The Committees enlarged upon the necessity of great care in the selection of this Provisional Commission, and recommend that the National Academy of Sciences be empowered to appoint its members, which they limit to seven or nine. The Committees also passed a resolution protesting against the passage of the Lamar bill now before Congress, and entitled "A Bill to establish a Department of Public Health." This was thought to give an unwarrantable concentration of power.

COOK COUNTY HOSPITAL passed into the hands of a new warden on the 1st of January. The air and the papers are full of the story of the mismanagement under the old regime. Doubtless there is some exaggeration in these reports, but the hospital under the former warden was bad enough. The management, it is claimed with some reason, was very weak, if not very corrupt and rotten. Nurses and other employees seemed to be responsible to no head, and to obey no authority. The expense to the public has been beyond all reason, and the institution has for a long time been outrageously inefficient. It is safe to say a thoroughly efficient warden might easily improve the sanitary condition of the hospital fifty per cent. over its average condition during the past year. The new warden, like a new broom, appears to be making a clean sweep. A marked change for the better is already noticeable; but the new incumbent has a very difficult task before him.

MEDICAL SOCIETIES OF CHICAGO.—A new medical society organized in a very quiet way, a few weeks ago, and called the Gynecological Society, has already given evidence of vigor and promise of usefulness. The new society is the third scientific medical

society now in active operation in the city, the "Chicago Medical Society" being the oldest, and the "West Chicago Medical Society" being next in age. The "Chicago Society of Physicians and Surgeons," once a flourishing organization, has not been heard from for several months. It will probably not be revived.

AIKEN vs. STATE BOARD OF HEALTH.—The Appellate Court of Illinois has just confirmed the decision of the lower court in the matter of Dr. Aiken vs. The State Board of Health. This is one step farther in the legal journey toward the establishment of the right of the State Board to revoke a physician's license to practise on account of unprofessional conduct.

WHY THE METRIC SYSTEM MUST BE ADOPTED.—[In the course of a lecture delivered before the New York Academy of Sciences, to demonstrate that the metric system must be taught more through the senses than to the mind, Dr. E. Seguin shows some of the advantages physicians would derive from the use of this quantitative language in practice, and in recording observations.]

"Foremost in human interest is the *uniformity of weights* in prescriptions, which would prevent the grave or fatal results attending the composition abroad of medicines prescribed here. And the *uniformity of measures* which would give the possibility of writing observations uniform—that is to say comparable at sight—with those of other nations.

"Then comes the possibility of mathematically accounting for the vital functions intrusted to the physician, in health at first, during their waste in disease, and in the course of their recuperation under treatment; and to make these individual records serve as mathematical elements of true medical statistics.

"These records, and the following ones, could be rendered much more valuable by being made on *metric paper* (a paper water lined, one way with the millimeter, centimeter, and decimeter-line; and the other way with centimetric and decimetric water-lines only). I will name, among the applications of this paper to the precision of our art, the tracing of the curves of the diurnal and pathological variations of the temperature, pulse, and respiration; the figures furnished by the hæmatometers, sphyrometer, dynamometer, various urinoscopes, etc.; the graphics of the myograph, of the sphygmograph, and of other self-graphing instruments; the drawings or photographs of the microscopic specimens, and other perishable or evanescent data, which lose part of their interest if their proportions have not been taken on an invariable scale.

"I can not omit the use of the metric paper-bands, on which, in important cases, must be telegraphed, from the bedside to the doctor's desk, the sudden break in the course of the vital functions, which foretells a crisis avertable only by telegraphic swiftness. Now that instruments of medical precision are invented as fast as the want of nicety in diagnosis demands them, nothing is more necessary than a man of concentrating their data on the uniform, and all but uniformly accepted plans of the metric system, of the metric scales, and of the metric paper. The great founders of the first societies of 'medical observation,' longed in vain for such means of record of their admirable observations as are now within the grasp of the whole profession.

"Let us, therefore, follow Europe in the use of the metric system; but let us show European physicians the use of the 'metric plan' in medical observation, beating them on their own ground, literally with a piece of paper.

"Our mind has come to that, but not our routine and automatism. Most of our medical schools and hospital clinics teach by the old weights and measures; few physicians prescribe in the metric language, and the druggists who know better (not all, of course), smile and *put up* according to direction. The best surgeons import their instruments for no other superiority over our home manufactures than their metric scale. The Massachusetts, Pennsylvania, and New York State Medical Societies recommend the use of the metric system; the U. S. Medical Marine Service makes it official and obligatory; and the Secretary of the Navy sarcastically remarks, in his last report to Congress, that *this change has caused no evil results*. Could we not benignantly promise the same *results* to private initiative?"

RESUSCITATING THE APPARENTLY DROWNED.—Prof. Burt G. Wilder, M.D., of Ithaca, N. Y., writes: "May I ask the profession, through your columns, for information as to *resuscitating the apparently drowned*? I desire to have the history of any clear case, including the following points: The name of patient and his residence; the date, cause of submersion, time of submersion, interval between rescue and treatment, condition as to pulse, heart, and respiration; methods employed, duration of treatment and result, with name of physician or operator. For the history of such cases, or for references to published accounts of them, I shall be very much obliged."

TREATMENT OF DIPHTHERIA.—Dr. M. J. Gahan, of Grand Island, Nebraska, writes: "For the past four years we have had in this city, during the fall and winter months, exhibitions of diphtheria to more or less extent, and prevailing during last winter as an epidemic, and reading in your valuable journal during the last year various letters and advices on its treatment, I take the liberty of offering mine. When the case is taken, on the first formation of the membrane I found the following supporting treatment and local applications effective, viz.: Tinct. ferri chlo. ʒi.; pot. chlo., ʒij.; aqua, ʒvij.; this to be used as a gargle four or five times a day, and the use of the tinct. ferri chlo. from ten to twenty drop doses every two hours. I have used this for the last four years in over two hundred cases, and it has yet to fail me for the first time when the disease was taken at its onset."

THE MORTALITY LIST OF 1878 IN PHILADELPHIA.—During the last twelve months 15,743 persons have died in that city. The number was 16,003 in 1877; 18,892 in 1876, and 17,805 in 1875. Of those who have died this year, 7,959 were males and 7,784 females; 3,905 boys and 3,480 girls, and 8,358 adults and 7,385 minors. The number of colored persons who have died is 957, and the number of deaths in the Almshouse, 495. These figures are from the books of the Registrar of Births, Deaths, and Marriages.

TAPE-WORM IN A CHILD THREE YEARS OLD.—Dr. Charles H. Bailey, of Bloomfield, N. J., writes: "Some time since I noticed a case of tape-worm in a child of three years, reported in the RECORD. The rarity of the disease at that age made the case interesting. As few such cases are reported, I venture to send you the history of the following case; if thought worthy of a place in the RECORD, it is at your disposal."

Case.—Clara S., aged three years. Patient has been a healthy child, her only sickness having been malarial fever during the past summer. In the month of October her mother remarked paroxysm of crying at night, and brought her to me for treatment for

worms. I gave her a dose of calomel and rhubarb, but with no success as regards her fancied trouble.

December 4th the father informed me that the child had passed pieces of a tape-worm. On visiting the family I was shown several pieces of a *tania solium*. The child seemed perfectly well, plump and well nourished, and the only other symptom of disease was the continuance of the night-crying. The child was directed to be sent supperless to bed, and a liberal dose of castor oil given on retiring. In the morning breakfast was to be withheld, and the following given:

R. Ol. felix mas. 4 grammes.
Syr. Tolutanum,
Mucil. G. acaciae. ʒij 30 "

M. Take half this mixture at one dose. In the evening of the following day the mother presented herself at my office with a quantity of tape-worm in a bottle. On careful measurement this measured *seventeen feet*, one unbroken section measuring thirteen feet. The head could not be found; the point of separation was at least well toward the head. No history of using raw or underdone meat could be obtained."

THE TRAINING OF NURSES.—The diet kitchen, and the lectures on nursing were first established in connection with the Philadelphia Woman's Hospital in the year 1872. The course of training extends over two years. The age for the pupils trained is from 21 to 45. The nurses of the Woman's Hospital are required to wear cotton gowns, no stuffed dresses being allowed when they are in service, to avoid the possibility of carrying about with them the seeds of contagious diseases. The first duty which is enforced upon them is strict obedience to the orders of the attending physician. In addition to this negative requirement, are the positive duties of registering the pulse, taking the temperature of the patient's body, etc. The most exact statement in writing is to be made of the patient's condition whenever required. In the diet kitchen the pupils are taught to prepare food for the sick.

The first general hospital in the city to open its wards to the pupils of the training school was the Philadelphia Hospital, in 1876. The nurses served there gratuitously for two years in exchange for the valuable opportunities offered in the range of cases.

This portion of the time of training is now passed in the Pennsylvania Hospital, where the pupils spend a year for practice in general surgery and medical dressing. The wards of the Orthopedic Hospital and Nervous Infirmary are also open to them. After this thorough hospital drill the pupils reserve the latter part of their term for private practice, and nurses may be obtained by any one upon application at the hospital.

The nurses sent out by the Woman's Hospital School for private practice carry with them a printed form of paper, upon which both the physician in charge and the patient or friends are requested to register whatever remarks or criticisms (confidential) may occur, and all these are taken into account in determining the grade of said nurses and their qualifications, as shown in practice. Prominent physicians in Philadelphia have shown their great interest in this school by delivering lectures in the Volunteer Course each spring, to the respective classes; and the graduated nurses find, on receiving their diplomas, their work ready for them at once under these physicians, or others who have the opportunity to observe their fitness as pupil nurses in the school.

Original Communications.

NERVOUS DISEASES CONNECTED WITH THE MALE GENITAL FUNCTION.

By GEORGE M. BEARD, M.D.,

NEW YORK.

I.

DISEASES of the male genital organs have both a medical and a surgical side. The surgical side, relating to inflammations, injuries, specific affections, and operative procedures of all kinds, is the exclusive province of treatises on surgery. The medical side, relating mainly to the nervous diseases and symptoms directly or indirectly connected with the reproductive function and organs, has thus far not been systematically studied by neurologists, while by surgical authorities it has been honored with only a partial and more or less unsatisfactory attention. The surgical writers have been the pioneers in observing the dependence of certain nervous maladies on genital disorders, and in recording their observations. On the whole, this fact is, perhaps, not entirely creditable to neurologists. The relation of the male genital function to the nervous system is intimate and complex, and is worthy of the best efforts of students of the nervous system.

Any one who is familiar with the literature of this branch of scientific inquiry, from the earlier periods down to the very latest and best surgical monographs in Germany, England, and this country, will allow that there has been a gradual tendency to refer, more and more, many of the morbid conditions of these parts to the nervous system; while, especially in German works on nervous diseases, there has been at the same time a tendency to study more and more closely the relation of this function as a causative factor in certain maladies of the brain and spinal cord.

There are, however, very many questions that are still open; many more that are regarded as matters of opinion only, and concerning which opinions are as numerous as those who write or lecture upon them; and not a few that science has passed utterly by. Some of these questions are of the very highest scientific and practical interest, and occupy the thoughts and attention of students and practitioners of medicine everywhere, and information in regard to them is earnestly welcomed, all the more because the inquirer is able to obtain so little assistance from medical literature or from the ordinary routine of medical instruction.

I purpose, in a short series of clinical papers, to attempt to answer some of these, so far as is possible to do so from my own personal observation and investigation in the study and treatment of cases of nervous diseases directly or indirectly connected with the genital function, presenting the cases, that may serve as suggestions for remarks, only in sufficient detail to make clear the special points involved.

In science the suggestion of a query that it is impossible to answer, or even an erroneous solution of a new problem, may sometimes be of service.

All purely surgical questions aside, there are quite a long series of diseases, symptoms, and hygienic problems involved in the relation of the genital function to the nervous system, in the study and solution of which every practitioner has a direct interest. Among these the following may be specified:

True spermatorrhœa, its nature and effects.

Involuntary emissions, when pathological.

Impotence, its varieties and treatment.

The relative harmfulness of natural and unnatural methods of producing the emission.

Sexual excess as a cause of nervous diseases.

Reflex nervous symptoms from morbid conditions of the glans and urethra.

The effect of nervous and other diseases on the genital function.

CASE I.—A man in middle life, from a distant place in the country, consulted me for involuntary emissions of many years' duration, and associated with neurasthenia and mental depression. The patient would not tell me his name nor give me his address, but stated that he had been engaged in the occupation of teaching, but had alternated it with more or less labor on a farm, and distinctly declared that the nervous troubles coming from his sexual debility had, so to speak, dislocated his whole life, and compelled him to abandon, in whole or part, what he had desired to do. The patient presented such a picture of physical debility as is often described in the advertisements of charlatans, but which are generally supposed to have been made up for the purpose of terrifying young men. His eyes were red, swollen, and watery; the face was haggard and melancholy, and there was the characteristic and almost diagnostic timidity. Memory, and the power of mental concentration, had been seriously impaired. The patient stated that the semen came away with the urine. On this point I was doubtful, but an examination made by Dr. Mittendorf fully established the claim.

The habit of masturbation, which had been faithfully followed in early youth, had been discontinued, according to the patient's statement; but the effects, true spermatorrhœa and neurasthenia, remained.

In regard to the results of the treatment advised, no information has been received.

This case confirms, so far as a single case can, the familiar but questioned claim that spermatozoa may flow away with the urine. In short, it was a case of true spermatorrhœa—a running away of the seminal fluid independent of any natural or unnatural excitement or of any irritation. Such cases are not very common. Again and again have I had the urine of patients afflicted with involuntary emissions examined for the purpose of testing this very point, and thus far only two cases of real spermatorrhœa have been found. All physicians know that, by the law of coincidences, a number of peculiar cases of disease may come together or in quick succession, and it is not impossible that a number of these cases might follow one another, and be at one time under the care of some physician; but, nevertheless, they are, comparatively speaking, infrequent.

Whether there is anything more than a relaxed, or, perhaps, passively congested state of the urethra at the mouths of the ejaculatory ducts, may be well doubted. In other words, the full history of such cases indicates a nervous more than an inflammatory condition. It is for this reason that the caustic treatment of Lallemand has been mostly abandoned. This case also demonstrates that the evil effects of the early habit of masturbation may, in some cases, be felt in maturity, and blast the whole life.

This is not a frequent result of this habit. It is but rarely that a case so striking as this is seen; but the possibility that such permanent results may follow the unnatural excesses of youth is of interest, scientifically and practically, and should be understood by the profession.

The effects of masturbation on the nervous system, severe as they are, do not, as a rule, remain through early and late manhood. They are functional more than organic, and disappear soon after the breaking up of the habit, or, at least, after marriage.

There is a disposition among patients to attribute all their nervous woes to their early indulgences, even when there is no clear proof of any connection between them. It is probable that the vast majority of those who commit excesses of this kind recover entirely, or almost so, provided they begin, within a reasonable time, to lead a natural life, either with or without marriage. The statistics of insane asylums in regard to this, as in regard to most of the accredited causes of insanity, are of little worth, since secondary causes are so often confounded with primary causes, and masturbation, which may be one of the effects of insanity, has often been noted as the exclusive cause. Violent masturbation is one of the symptoms of insanity, and when a patient is brought to an asylum with this habit firmly fixed upon him, it is a natural, but not always a just conclusion, that the insanity is a result of the habit.

The capacity of the human system for bearing and for recovering from the temporary evil effects of sexual excesses in youth is one of the most interesting facts in this part of physiology. Very few nervous patients, whether suffering from organic or functional disorder, but on close cross-examination confess to early excesses; but to assume, therefrom, as many German writers have done, that such excesses have always caused the nervous disease, is most unjust.

CASE II.—During the past year I was consulted by a gentleman of education, scientific attainments, and excellent good sense, for true spermatorrhœa of many years' standing, brought on, as such cases usually are, by masturbation commenced in very early youth. The patient was thirty-six years of age, and had not practised the habit with any regularity for eleven years. With nearly every stool semen was discharged, as microscopic examination proved. The patient, unlike most of these cases, was not at all hypochondriacal, but considered his symptoms in a truly philosophic spirit. He was, however, like the majority of such cases, a sufferer from neurasthenia—a disease of the nervous system which I have elsewhere defined and described in detail. The special symptoms of neurasthenia, of which he complained, were insomnia, nervous dyspepsia, asthenopia, mental and physical debility. The intimate and direct dependence of the weakness of the eyes on excitation of the genital function was in this case illustrated most remarkably. He was sufficiently intimate with a young lady to sometimes embrace and dally with her; and a number of times these dalliances led to an orgasm with ejaculation of semen. For a few hours after these ejaculations there would be a feeling of great and most satisfactory relief; but the next day there would always be a peculiar lassitude of the head and body, with nervous trepidation in the hypogastric region, annoying wakefulness at night, and exacerbation of the irritability of the eyes; in the patient's own language, "every hour of sexual excitement has reverberated on my eyes."

The question in which this patient was specially interested was whether he could get married; whether an engagement that he had formed must be broken off; and he was desirous to learn whether there was any difference in the effect on the nervous system between ordinary, normal coitus and the ejaculation produced by simple dalliance. An able and eminent physician whom he had consulted had positively as-

sured him that marriage would cure him. My advice was to get married, but to first tone up his nervous system by various sedative and strengthening treatment, continued for a number of months, and when he got married to be very moderate in sexual indulgence.

The patient followed half of my advice, but not the other half; he married at once or very soon, and without taking any tonic treatment. It should be noted that one reason why he did not take the course of treatment indicated, was that he was abnormally susceptible to tonics, and indeed to medicines of all kinds; this was, in fact, one of the symptoms of his neurasthenia.

A few weeks after marriage the patient came to my office and reported that normal sexual intercourse was even more injurious to him than the orgasms of dalliances, and that even one coitus a week he could not bear, and he politely intimated that I had given him unwise advice. In reply, I reproved him for following only part of the advice given, and suggested that he at once begin taking the sedative and tonic treatment. The internal use of ergotin, belladonna, and bromide of camphor, the systematic use of the cooling catheter and cooling rectal sound to act on the irritable prostate, were advised, while living platonically, or almost so, until he became stronger.

This case is instructive and suggestive in many directions. First of all it raises the query, concerning which there has been much assumption without careful analysis or clear demonstration why and to what extent unnatural methods of producing the sexual orgasm differ from the normal coitus.

The ejaculation produced by normal sexual intercourse is the resultant of these six factors:

1. Friction.
2. Pressure.
3. Warmth.
4. Moisture.
5. Suction in slight degree.
6. Mental influence.

The first peculiarity of the various unnatural methods is, that they throw the burden of the excitation on some one or two, or, at least, a part only of these six factors, compelling the mind, or friction, or pressure alone, or together, to bring on the orgasm.

In the unnatural methods the mental influence is relatively too strong; there is too much of the subjective. It is well established that long and frequent dwelling upon sexual matters without any external, objective irritation whatever, is very harmful to the nervous system.

In the case here narrated the ejaculation was produced mainly by mental influence, though combined with pressure and possibly friction, and the process was undoubtedly much more prolonged than a normal coitus.

Secondly.—Another fact with regard to the unnatural methods is that they are more prolonged, thus making severer drafts on the nerve-force.

Thirdly.—The unnatural methods are carried out more frequently than the natural one; they can be done at almost any time, and do not, like the natural coitus, require the presence and consent of another party.

Fourthly.—The unnatural methods are often begun very early in life before coitus would be even attempted.

In several of my cases the habit of masturbation was taught in childhood by nurses or servant girls; and in all or nearly all the cases of sexual or general debility, induced by masturbation, that have been un-

der my care, the habit was formed either before puberty or just at puberty—certainly much earlier than sexual intercourse is expected.

It may properly be doubted whether the habit of masturbation, commenced at the age of twenty and practised only about as frequently as one would indulge in coitus, would lead to very disastrous results, at least to such melancholy symptoms as are represented in the above cases.

When we consider the universality of the habit of masturbation, the wonder is not that there is so much but so little of injury resulting from it. There is a prevalent belief that this vice is on the increase, and that it is peculiar to civilization. The probability is, rather, that it is relatively diminishing. There is evidence that it is practised far more in barbarous and semi-civilized people than among the highly civilized. We notice its effects more in modern times and in a high civilization, because our nervous, sensitive, impressible organizations cannot so well bear abuse of any kind. A degree of self-abuse that on the American constitution, as it was fifty years ago, would have had no effect sufficiently perceptible to attract attention, now induces an immense array of symptoms of neurasthenia that drive the sufferer in despair to the physician's office, or more frequently to the writings of charlatans. Some of these cases, no doubt, bring on or intensify their troubles by reading and worrying about them; but that cannot be said of all; it cannot be said of the case noted above.

The nervous disease, inebriety, illustrates the same principle. During the past half century the vice of excessive drinking has greatly declined among the better classes of this country; but, at the same time, the disease, inebriety, has been perceptibly on the increase, for the reason that the nervous temperament of the modern American will not bear free indulgence in alcohol.

This case also shows that it is possible for one to be in apparent health, able to engage in active duties, and yet be so nervously susceptible that even occasional sexual intercourse is injurious. If this man indulged but once a week he suffered from wakefulness and other symptoms of functional nerve disorder. This observation is instructive as indicating a possible cause of failure of our remedies in some instances.

That this peculiar susceptibility is not confined to cases of spermatorrhœa is proved by the following case:

CASE III.—A physician of middle life complained, among other symptoms of nervous exhaustion, of a special type of agoraphobia; he could not go any distance from his office without suffering, and the farther he was from his office the greater his distress. There was headache, and also there were various head symptoms; but the appetite was excellent and the muscular strength was equal to the average of men of his age and size. When requested to visit a patient he might be found at work in his garden, and yet unable to respond to the call for the one reason that he could not go any considerable distance from his home.

Under various treatment, including general faradization, counter-irritation at the nape of the neck, and internal medication, he so far improved that he could attend to his profession, although the relief is not perfect and he still takes treatment.

The point in the case of chief interest just here is, that after long and careful observation he concluded that even occasional sexual intercourse was harmful to him; and what is of especial interest, is the fact that the injurious effect was not felt until the *second day* after indulgence.

The question whether agoraphobia and allied nervous affections are not pretty directly under the influence of the genital system is suggested by cases like the above. One fact, according to my own observation, is quite clear; namely, that all maladies of this class appear almost exclusively during the period of greatest sexual activity—between the ages of twenty and fifty—very rarely before fifteen or after fifty-five or sixty. Childhood and old age have diseases enough, and diseases of debility and exhaustion; but they do not have the special and peculiar forms or manifestations of exhaustion known as agoraphobia, spinal irritation, cerebral irritation, and hysteria. Sick headache—a type of this family of disease—does not usually appear before puberty, although I have known exceptions to this rule, and generally disappears between forty-five and sixty, as all students of this malady well know. It is quite possible that simple activity, or a condition of *readiness for activity* of the genital organs, without abuse in any form, may, by reflex action, excite various nervous symptoms and disorders which disappear as the genital activity declines. Cases of hysterical trance, like those of Mollie Fancher, usually (I will not say always) begin and end during the period of sexual activity.

CASE IV.—A man somewhat under middle life, who had been very active in his profession, was prostrated with a powerful array of nervous symptoms, in which the sexual organs shared. There was increase of desire without increase of capacity. During the night there would be persistent erections, which were followed by pain in the region of the testicle and bladder.

Although this patient had usually a good appetite, and was able at times to go out and attend to business; and when unable to leave the house or even the bed he could, and did, carry on important affairs by dictation; yet during all this period he could not indulge in coitus without suffering terrible prostration and palpitations. For that reason he habitually abstained.

In this case there was no evidence that sexual excess had anything to do with the nervous symptoms; but when in that exhausted state, sexual excitement seemed to be injurious. This was not a temporary, but a long-standing condition. I have just been consulted by a fourth case—the details of which will be subsequently given—where normal sexual intercourse even but once a week is followed by insomnia and nervousness.

In an interesting paper read before the Academy of Medicine, February, 1874, Dr. Otis reports a number of cases where urethral contractions, congenital or acquired, were the starting-points of a variety of morbid nervous phenomena, such as discomfort in the perineum, involuntary emissions, frequent micturition, pains in the back, testicles, groins, and thighs, and a feeling of wetness at the glans penis, and so forth.

Some of these observations I have been able to confirm. I have known a very slight and temporary irritation of the anterior portion of the urethra to cause frequent sensations along the inner part of the thighs, as though of dropping water—indeed, quite the same feeling that would be experienced if drops of cold water fell from a moderate height on the skin; and it would appear that these abnormal feelings may be excited not only by the few drops of urine retained behind the stricture, as Dr. Otis suggests, but by a mere irritation, without any retention or interference with the flow of urine.

In this line is the painful, though usually temporary but sometimes most distressing, pain in the perineum

that follows sexual intercourse or the act of defecation. A medical gentleman who once consulted me in regard to this symptom, said that it was at times quite hard to endure. It seems, as a rule, to arise only when there has been excess, or when the act is forced by unnatural methods; but this rule is not without exceptions; in a sensitive organization it may appear after ordinary indulgence or an easy defecation.

Diseases of the urethra may be effects as well as causes of disease in remote parts of the body. Thus, Dr. Lewis Fisher, of this city, has communicated to me the facts in regard to a case of obstinate urethral discharge which resisted all treatment, until at last he succeeded by a mechanical appliance contrived for the relief of the ligaments at the bottom of the feet; the ligaments had been strained in long marching.

The phenomena of reflex action in the causation and cure of disease, much as they have been studied, are yet far from receiving the attention that they merit, not only as scientific curiosities, but as practical aids in the diagnosis and treatment of nervous diseases. Pain of a persistent character in the back of the neck and head I have known to disappear on the cure of piles; dyspepsia, as all know, often affects every part of the body, except the stomach; headache in women, I have known to disappear instantly on faradization of the uterus; overuse of the eyes causes headache and neuralgia.

CASE V.—At the present time I have under observation a young man who is the victim of insomnia, flushings of the face, with periods of depression. The only symptom of which he complained on consulting me at first, was insomnia; but on detailed examination it was soon found that involuntary emissions were annoying him, and that the long habit of masturbation was not fully overcome. On examining the parts it was found that the foreskin was so attached to the glans that only a very small orifice was left for the escape of the urine. It was and is a question whether the insomnia and other nerve-symptoms are produced by the masturbation and the involuntary emissions, or reflexly by the elongated foreskin. In order to settle this question, it was decided to first try only medical treatment; and he was placed under the external applications of faradic electricity, and, internally, co-nium and digitalis were prescribed, and also the zinc combination, which, in nervous disease, I am accustomed to make much use of, particularly where sedation is required—bromide of zinc, valerianate of zinc, oxide of zinc, equal parts, sometimes adding small doses of the phosphide of zinc, or belladonna, or physostigma, or ergot, increasing the quantity from time to time. Under this treatment, combined with attention to diet, he is already improving; but if the result is not perfect, an operation may well be advised; for the meatus is so small that urination is a tedious process, and the passage of a large sound is impossible. A constant life-long irritation of this kind might surely excite all the evils from which he suffers, as Dr. Sayre's cases demonstrate. In cases like this, reducing the quantity of food taken, and dispensing for a short period with animal food entirely, are valuable suggestions. In England great cures of incontinence of urine in children have been reported by the simple expedient of confining the patients to purely vegetable, fruit, and farinaceous diet, all meat being for the time entirely interdicted. I have now under care a patient who has been relieved of a very large number of distressing symptoms by reducing the quantity of his food about one-half, the quality remaining the same; the case is a chronic one, and he is yet far from

health; but if like improvement had followed directly and demonstrably from any medication or any method of treatment, the result would have been regarded as brilliant.

CASE VI.—Some years since, a man in middle life consulted me for a certain grade of impotence, which, as he had just married a second wife, was a cause of much alarm. He was, in all other respects, in absolute health; but the decline in sexual vigor was decided. Under a course of treatment, mainly electrical, he fully recovered, and I believe the results were permanent. There was no atrophy of the parts, as we sometimes see in cases of this kind; there was simply functional debility, the effect of previous overuse, combined with undue anxiety lest he might not be equal to the duties of his second marriage. The feature of chief interest in his case was the absence of all other morbid symptoms, either local or general—the coincidence of perfect health with weakness of the genital function. This is not an exceptional case; I have seen many such; but their significance is not thoroughly understood. A physician of very large experience, and of exceptional powers of observation, once remarked to me that he had always supposed that impotence was an effect or accompaniment of general debility. The truth in this matter would appear to be, that sexual excess or abuse in *strong* constitutions is likely to result in local genital debility; the same excess in weak constitutions is likely to result in *general* debility, or, at least, disorder in other and remote organs. The weak cannot abuse themselves long enough to bring on local trouble; they are warned by general nervous symptoms that compel them to desist; while the strong, having no such warnings, keep on in their excess until the genital function itself gives way; and when finally they come under treatment they are harder to cure than those of more sensitive organizations. When a sensitive, impressible, finely organized youth abuses himself sexually, the first effect and sign of that abuse is not in a weakness of the genital function, nor even in any disorder whatever of the genital apparatus, but in nervous symptoms in other parts of the body, as the head, heart, or eyes, or, very frequently, the stomach and spine. Thus, he becomes generally demoralized, while the special function, the abuse of which is the source of all his troubles, is unaffected, and, indeed, is so active as to be annoying.

This same generalization applies to all the functions of the body. Thus, the cramp of writers, musicians, and telegraphers occurs almost always, with an exception here and there, in persons of considerable, if not unusual strength; the very weakly and sensitive cannot write, or play, or telegraph long enough to bring on the local disorder, but give way first in other parts than those specially concerned in the acts of writing, playing, or sending messages. This is a partial explanation of the fact, that all these disorders are relatively more frequent in males than in females; and also of the fact, that out of more than one hundred cases that I have studied, in more or less detail, nearly all are persons of good, if not exceptional health, the cramp being their chief, and in many instances their only affection, and the very first evidence that anything was wrong with the system. Some of the cases of musician's cramp—piano-players, organists, and violinists—that I have lately seen, are magnificent specimens of physical development, with absolutely perfect health, and muscles almost as hard as iron; one can but envy them, and feel sometimes quite willing to endure their local debility for the sake of their general vigor. Of the few incurable cases of

impotence that I have seen, all were in persons of otherwise excellent or extraordinary health.

Impotence is a symptom of many gradations; that between the mildest and severest varieties, shade into each other, and are not always or usually precisely defined. Among the different forms that it assumes (aspermation excluded) are the following:

1. Slight decrease both of desire and power.
2. Slight decrease of power with increase of desire. This is analogous to dyspepsia with morbid appetite. This second form is sometimes attended with premature or too early emission.
3. Temporary and abnormal increase both of desire and power. This third form is one of the early symptoms of certain diseases of the spinal cord, sometimes of the brain also. It generally indicates the congestive stage of spinal disease.
4. Great diminution or utter loss both of desire and power. This latter form is the worst, least amenable to treatment, and it is the form that is often found in the strongest and hardest constitutions.

NASO-PHARYNGEAL CATARRH—VARIETIES, TREATMENT.*

By WM. F. DUNCAN, M.D.,

ASSISTANT TO THE BELLEVUE THROAT CLINIC, MEMBER OF THE N. Y. LARYNGOLOGICAL SOCIETY, ETC., ETC.

At this season of the year, catarrh being very prevalent, it has occurred to me that a few words to the profession about its treatment would not be amiss. It has been a matter of regret to all thoughtful medical men that the treatment of this common disease should be left almost entirely to quacks and irregular practitioners. Looking upon it from this stand-point, I desire to give my experience, in treating over a thousand cases of catarrh, to the profession, and to proclaim my conviction that it is in a very large majority of cases a curable disease. This belief arises from a very careful observation of these cases, continued until a cure was established. There is little that is new or mysterious in the treatment, which consists for the most part in the proper and thorough application of old and trusted remedies. The necessity for greater care in the examination and diagnosis is earnestly urged, and a failure to cure the patient may frequently be attributed to improper diagnosis of the form of the disease. The success of the treatment, in my hands, is due to the attention given to cleansing the mucous membrane before making any applications of medicine. It is the essential consideration in treating the mucous membrane of any part of the body, and, in the nasal cavities, which are small and easily blocked up with the excessive secretion of catarrh, its importance cannot be over-estimated. Inasmuch as the different varieties of catarrh require a distinct and separate line of treatment I have thought it advisable, even at the risk of presenting to my readers a good deal of matter with which they are already familiar, to describe in a brief form the clinical history of the disease and the diagnostic points of each form.

A description of a chronic catarrh of any mucous membrane will answer for that of nasal catarrh, which is a chronic inflammation marked by an afflux of blood to the parts, producing swelling, hypertrophy, or atrophy, and an alteration in the quantity or quality of the secreted mucus. It may follow imme-

diately an acute attack, or, what is seen more frequently, will set in after repeated attacks of acute catarrh, the result of constantly catching cold. Continued exposure to irritating gases, or an atmosphere charged with dust, will produce it. Hence the followers of certain trades are often its victims, as stone-cutters, flower-makers, the employees in tobacco-factories, and so on. The use of tobacco undoubtedly occasionally produces post-nasal catarrh. Measles, scarlet-fever, diphtheria, and small-pox, leave the patients with chronic coryza, syphilis, scrofula, tuberculosis, malaria, and, in fact, any depressing disease places the system in a condition to get up a catarrh. Valvular disease of the heart and emphysema, from their interference with the circulation, may produce it. Also foreign bodies, such as cherry-pits, buttons, and even teeth, which have been introduced into the nostrils of children, unknown to the parents, and left there. Again, there are many persons, outside of any diathesis, who, seeming to enjoy perfect health in all other respects, have catarrh in the worst form. More catarrh probably occurs inland than on the sea coast. Chronic catarrh may be divided, from location, into nasal and post-nasal. There may be a nasal catarrh limited to the nares proper, stopping at the posterior ends of the turbinate bones and septum; a post-nasal catarrh, confined to the vault of the pharynx; and finally, a catarrh of the whole tract, including the posterior wall of the lower pharynx, called naso-pharyngeal catarrh. Pathologically speaking, there are three varieties, with possibly a fourth: the simple, the hypertrophic, and the atrophic. The fourth division, simple ozæna, will be treated as a complication.

Simple Catarrh.—In a simple catarrh there is an inflammation of the mucous membrane, manifested by an alteration in the quantity of the secretion, which is more or less profuse, according to the severity of the disease. It is changed in quality, becoming thicker and yellow if the grade of inflammation be high. The afflux of blood to the parts deepens the color of the mucous membrane to a fiery red, and increases the nutrition of the glands so that they manufacture and pour out an abundance of mucus. The discharge is filled with mucus, mucus-pus, mucous and pus corpuscles, half-formed cells, and broken, detached epithelium. The rhinoscope shows little swelling, but simply an intense redness, and the whole surface covered over with patches of stringy, whitish secretion. There is little or no pain, but an uneasy sensation and a tendency to frequently blow the nose and hawk to get rid of the excessive discharge. The most prominent and annoying symptom is the constant running from the nose. This disease may terminate spontaneously or be cured after the lapse of some weeks. If, however, it be allowed to continue for months it may run into the second or hypertrophic form, which is really another and advanced stage of the disease.

Hypertrophic Catarrh.—In this form the inflammatory action has produced such a hyper-nutrition that the cells form new hypertrophic tissue, which lies in great ridges in the vault, on the posterior ends of the turbinate bones and septum, almost blocking up the nares on the Eustachian tubes, and in the fosse of Rosenmüller. The pharyngeal tonsil, a collection of follicular glands in the vault, similar in appearance and analogous in function to the tonsils of the fauces, is very much swollen. It is frequently the starting-point of a catarrh from which the disease works both forwards and backwards. Single enlarged follicles are seen in the vault, and in some cases on the rear of the septum. The whole appearance is that of an hypertrophied, boggy, inflamed

* Read before the N. W. Medical and Surgical Society.

mucous membrane. The same polypoid thickening of the anterior ends of the inferior and middle turbinate bones exists, as of the posterior, and upon looking into the anterior nares they appear like fleshy tumors. Strings and rolls of mucus are spread over the surface and bridge the recesses and fissures. The symptoms are sufficiently aggravating. The secretion is enormously increased, yellowish-green in color and very sticky. Sometimes it is a reddish-brown, like the rust-colored sputa from pneumonia, the result of the coloring matter of the blood transuding through dilated blood-vessels. This is usually seen, when present, in the expectoration, in the morning, of the matter collected behind the palate during the night. If the trouble be confined to the vault there is a sensation of a foreign body behind the palate, a stuffy sensation, and an almost uncontrollable desire to draw it down and hawk it up. Even after removing a roll of mucus the swelling of the parts preserves the disagreeable sensation, and the hawking is frequently repeated. This action causes hyperæmia and elongation of the uvula. There is ringing in the ears from invasion of the Eustachian tubes by the catarrh, or temporary deafness from plugs of mucus completely stopping their orifices. In some cases catarrh of the middle ear, with its serious consequences, results. The dropping of mucus into the throat during sleep occasions a coughing spell in the morning to remove it. Again it is swallowed, and impairs the digestion and appetite, and interferes with the general health. When the catarrh extends forward into the nares the swelling of the mucous membrane nearly closes them, interfering with nasal respiration, and causing the patient to breathe through the open mouth. This produces a peculiar expressionless countenance, which, taken with the alteration of the voice due to the absence of nasal sounds, is quite characteristic. It also causes snoring during sleep. The inflammation may extend into the nasal ducts, producing a watery discharge from the eyes into the frontal sinus, making a frontal headache, frequently a great annoyance, and into the antrum, and set up a severe neuralgia. Inspection of the post-pharyngeal wall shows a catarrhal pharyngitis, which has a follower in a hyperæmia of the laryngeal mucous membrane, producing a huskiness, and a desire to scrape the throat. It is quite distressing to public speakers and singers, whose voices improve with the cure of their catarrh. Dyspepsia frequently results from extension of the catarrh down the œsophagus. Also previously existing dyspepsia will aggravate the catarrh. The sense of smell may be greatly impaired, particularly when the catarrh is an old one, and involves the superior and middle turbinate bones, and the upper part of the septum, in whose mucous membrane reside the terminal olfactory nerves and cells. This form of catarrh may persist for months, and gradually glide into the atrophic or dry variety or stage.

Atrophic Catarrh.—This condition of atrophy may also develop from a simple catarrh. It is very common in people of middle and advanced age, and is rarely seen in young children. Probably the interstitial pressure on the afferent vessels, from the hypertrophic tissue in the sub-epithelial structure, long-continued, robs the parts of their necessary nutrition and atrophy sets in. The glands soon suffer, losing a part of their secreting cells, which results in a diminution of the secretion. The entrances to the glands becoming contracted, some are totally destroyed, while others preserve a few secreting cells which may be stimulated to activity by restoring their nutriment. The absorption of tissue frequently goes on to such an extent as

to cause an actual increase in the size of the cavities.

Examination reveals the mucous membrane stretched tightly and smoothly over the bones and cartilages. It is perfectly dry, glazed, and shining. It is highly colored, owing to being so thin that the blood-vessels show through it very plainly. Sometimes the veins are engorged and varicose, and easily burst, making frequent slight hemorrhages, from which the blood dries in hard black crusts. The septum and turbinate bones may become as thin as the blade of a knife. Slight erosions now and then occur on the septum and anterior end of the inferior turbinate bones, from which the patient will pick hard crusts, which re-form every few days. Crusts and rolls of dried mucus are found in the nares, the result of the secretion of some part high up in the meatuses not yet atrophied. The nares being enlarged, quantities of dust are inhaled and spread out over the surface. Nearly always the posterior pharyngeal wall is in the same condition of atrophy as the parts above. It is called pharyngitis sicca. A combination of atrophy and hypertrophy may exist. There may be atrophy of the nares and hypertrophy of the vault, diminished secretion from one, and increased secretion from the other, or the reverse.

The different conditions require different treatment.

The subjective symptoms of dry catarrh are frontal headache, dryness of the nose and pharynx, decrease of the olfactory sense, absence of secretion, and the formation of hard dry crusts.

Ozæna.—One of the problems heretofore difficult of solution by the profession has been to determine what is *ozæna*; the popular impression being that it was a catarrh produced by syphilis, and that in some way syphilis was always answerable for it. With this idea in mind, specific remedies were invariably given, and with very varying results; some cases yielding to mercury and iodine, while others would grow worse under the same treatment. The former were undoubtedly syphilitic, while frequently the latter never had any venereal disease, and in them a great deal of mischief was caused and no relief granted. The matter is somewhat cleared up by dividing *ozæna* into simple *ozæna* and syphilitic *ozæna*, and hunting up the cause for the offensive odor which is characteristic of each. When syphilitic, it is the result of decomposed secretion from ulcerations, caries, and necrosis, either of which is always present. There are crusts and plugs and rolls of dead tissue filling up the nostrils, making a world of stink. The color of this offensive mass is dark gray. There is a vicious, sanious, and very copious discharge. The bones ulcerate, die, and are discharged piecemeal, causing fearful disfigurement, discomfort, and pain. This is the typical *ozæna* of the older writers. Simple *ozæna*, however, is very different. It occurs in patients who are otherwise perfectly healthy, is unaccompanied by any ulceration, and yet has just as offensive an odor as the syphilitic variety. The cause of this is probably such as was first suggested by my friend Dr. Bosworth. The disease resides in the accessory cavities of the nose—the frontal, sphenoidal, and maxillary sinuses, either of which has a capacity of at least two drachms—and these, opening by small outlets into the nares, retain the secretion poured out by their inflamed mucous membrane until it becomes decomposed, and enough has been produced to cause an overflow and a discharge of their contents. This offensive product oozes out and coats the nares with a thin, close-fitting, shining, yellowish-green pellicle, which can be seen upon examination. Its appearance

is quite characteristic, and can scarcely be mistaken. When it is carefully washed away so that none is visible on inspection, the odor disappears for several hours—a day or two—until more is discharged from the sinuses. It is difficult to detach it, as it clings very closely to the surface underneath, which, after its removal, appears very much reddened, but is clean, intact, and free from ulceration. In both varieties the patients are deprived of their sense of smell, and oftentimes, until informed by their friends, are unaware of the disgusting odor they emit.

Owing to lack of space, further reference to the complications of catarrh will be omitted.

Treatment.—The successful treatment of catarrh is largely confined to local applications, although the necessity for treating internally every disorder of the system is earnestly urged. Always in treating a diseased surface cleanliness is recognized as the chief requisite. This necessity, I repeat, is especially emphasized in dealing with a diseased mucous membrane, which must be thoroughly cleansed before the application of medicine is made. The mucus is often very tenacious, and secreted in cavities difficult of access, and yet it is possible to remove most of it by the methods described. The fact that alkaline solutions have a solvent effect on mucus is utilized, and all of the cleansing solutions contain some form of alkali; and, as in many cases there is a decomposition of the retained secretion, an antiseptic or disinfectant is used. Any combination of these two medicines, in weak solution, will answer, but that which seems to be as efficient as any, and in use at the clinic, is Dobell's solution.

It is used with the atomizer, the post-pharyngeal syringe, and the nasal douche. The nasal douche of Thudichum has received too much praise and too much condemnation. It has a position in the armamentarium worthy of a moment's consideration. When a catarrh is simple, there is nothing but an excess of secretion, and it is limited to the anterior nares, the use of the nasal douche is serviceable. It is valueless in any other case, however, because the solution washes only a limited surface. It enters one nostril, and, flowing upward around the rear of the septum, passes out of the other, cleansing only the inferior meatuses, and does not reach the whole of the vault. Again, it does not run with sufficient force to be of much value when there is a copious sticky secretion. There is some danger to be apprehended from the solution entering the Eustachian tubes, beyond the valvular portion, if used carelessly. This liability is reduced to a mere nothing if the patient be directed to hold the nose downwards, and while the current is passing through the nostrils to breathe through the open mouth. Also the vessel or reservoir must not be placed more than two feet above the level of the head. Common salt ℥ i.—aq. Oj. may be of service. I have abandoned the douche because of its limited service, except when used with a curved nozzle, like the pipe of the post-pharyngeal syringe, which is passed behind the soft palate, and the solution runs out of both nostrils. I recommend this to be used by the patient at his home. The best method of using the cleansing solution is with the post-pharyngeal syringe, which is both safe and efficient. The solution

can be driven with a great deal of force without danger of its entering the middle ear, because the direction of the stream and the Eustachian tubes is the same, downwards and forwards. It is to be entered flat on the tongue, which is depressed by its nozzle, its point introduced quickly behind the palate, and the contents suddenly and forcibly ejected by driving home the piston, and the syringe withdrawn. When there are crusts and plugs of mucus it may be necessary to repeat its use a dozen or more times at a sitting before they are washed away. Always examine to see that the surface is clean. When skilfully used it gives no pain, and is tolerated by any patient. Sometimes the sticky pellicle in ozæna will be loosened and drawn down from the upper meatuses until it reaches the anterior nares, where it will remain. It can be dislodged by throwing a stream with the same syringe, first into the nares in front, and then from behind the palate. The solution can also be used in a spray driven by compressed air, either by a hand-ball atomizer, or a pump and receiver. The last is very efficient when used with about thirty (30) pounds pressure, and will dislodge mucus from the superior meatuses, and even the entrance of the sinuses. It is better for children than the post-pharyngeal syringe. If with all these methods you fail to clear the nostrils, as you may do in syphilis, loosen the crusts with a probe and remove them with long slender forceps.

The next step in the treatment is the application of the medicines, adapted to the case, which is made in the form of spray, powder, or solution. The spray spreads out in every direction, and reaches cavities otherwise almost inaccessible, and is therefore the choice method. In simple catarrh the object in view is to reduce the amount of inflammation by the use of astringents. Select astringents of different strengths and kinds to suit each case. For a standard astringent, sulphate of zinc, gr. xv.—aq. ℥ j. is a good one. If the case be a mild one, do not use it stronger than three grains. If the catarrh be of long standing see the patient three times a week, and in the intervals let him use the cleansing solution home, with Delano's atomizer, or the post-pharyngeal douche. Ferrie-alum, gr. v.—xx. to aq. ℥ j., is valuable when there is excess of secretion and little sensibility. Chlorate of potash, nitrate of silver, tannin and chloride of zinc may be used. Ring the changes on the astringents until a good one is found, and stick to it. When pain, lasting longer than half an hour, follows the use of the astringent, use a spray of U. S. solution of morphine. When there is hypertrophy to deal with, stronger applications are needed. Caustics can be applied with a probe, one end of which is tightly wrapped with cotton. With such a probe, one end of which is bent at right angles, the short arm of which is about an inch long, applications can be made behind the palate to the vault. The hypertrophied tissue must be destroyed, crushing it with forceps, cutting it with a knife, and galvano-cautery are allowable. The polypoid thickening of the ends of the turbinate bones can be touched with caustics, applied by means of a probe passed through a shield. Curette the vault when there is adenoid degeneration. In both the above forms of catarrh excess of secretion is the prominent feature requiring treatment.

In the atrophic form the secretion is absent, and the glands need to be stimulated to action, and astringents avoided. A spray from a weak solution of iodine, gr. v.—x. to aq. ℥ i., or tr. sanguinaria ℥ i. to aq. ℥ i., may be used. Sang., myrrh, and lycopodium in powder, blown into the nostrils, are a valuable stimulant. Continued applications to a

perfectly dry membrane bring a reward after a time, when the stumps of the glands begin to take on action and pour out the secretion.

The simple ozæna is treated by carefully removing the pellicle every day or two, and then using an astringent spray, after which iodoform blown into the nostrils in powder is effective. The nasal passages must constantly be kept open so as to allow all the offensive matter to flow freely out of the accessory cavities. The iodoform is not annoying to the patient, and, if care be taken not to get any of it on the clothing, will not be very disagreeable to others. When syphilitic ozæna exists the local treatment is the same. In addition, the usual internal remedies are employed. If any dead bone can be detached take it away at once. Finally, take up each complication singly and overcome it, remove all foreign bodies and tumors, fight every disease and diathesis with the proper remedies, and the same measure of success will be met with in treating catarrh as is encountered in treating other chronic disorders.

266 W. 43d STREET.

REINTERMENT OF THE REMAINS OF JOHN HUNTER, IN 1859.

A BRIEF SKETCH OF HIS LIFE AND WORKS.

(Abstract of a Paper read before the New York Academy of Medicine,
January 2, 1879.)

By ELLSWORTH ELIOT, M.D.,

[NEW YORK.]

WHILE spending a few days in London, in the spring of 1859, I saw in the advertising columns of a newspaper a notice that the remains of John Hunter, recently discovered in a vault beneath the Church of St. Martin-in-the-Fields, would be reinterred in Westminster Abbey.

[Here Dr. Eliot gave an interesting account with reference to obtaining a ticket of admission to the ceremony. He was the only American physician present.]

The grave-diggers in the old church showed me the coffin, covered with cloth, time-worn, but in good condition. It had been placed, at the time of his death, in Vault No. 3, which had been subsequently filled with coffins from the bottom to the top, and was found underneath many and toward the back part of the vault. The inscription upon the brass-plate was easily read: "*John Hunter, Esq. Died Oct. 16th, 1793, aged 64 years.*" In an English paper it was stated that it had been discovered after a search of two days. This did not seem incredible after viewing the extent of the vaults and the number of coffins placed therein.

Before the appointed hour, I was at the door, and was admitted "to the Jerusalem Chamber, through Dean's Yard." The chamber was venerable for its great age and historical associations. There King Henry IV. had died nearly four and a half centuries previously. "Even there my life must end," are his words, as we find them in Shakespeare. It was soon filled with the distinguished surgeons and physicians of London. Among others, Mr. John F. South, the editor of *Chelms Surgery*, through whose kind direction I had received my ticket. An official of the Abbey soon announced that it was the hour for service, the order for daily evening-prayer, the musical portion being modified as suited the occasion. Apart from this, no word in praise or memory of the distinguished dead was spoken. No words could

have been added to the impressive solemnity of that hour. The stately and solemn chant to the Psalm; the *Magnificat* and *Nunc Dimittis*; the voices of singers and the accompanying organ, as the music softened and swelled and echoed beneath the Cathedral's magnificent arches; Handel's anthem, "When the ear heard him, then it blessed him; when the eye saw him, it gave witness to him; he delivered the poor that crieth, the fatherless, and him that hath none to help him;" and the sublime chorus, "His body is buried in peace, but his name liveth for evermore;" and, lastly, the "Dead March in Sampson," as the coffin, borne on men's shoulders, was carried to the grave—these combined to make an indelible impression upon the mind and heart, which cannot be described.

"When life is old,

And many a scene forgot, the heart will hold
Its memory of this."

It is a singular circumstance that Mr. Hunter's widow was unable to defray the expense of a burial of the remains of her husband in the Abbey at the time of his death, and for this reason they were placed beneath the church of the parish in which they resided.

The incidents which I have attempted to describe naturally lead to the inquiry, Who was John Hunter, and what did he do to deserve and receive such unusual honors? Sixty-six years after his death, a period of time during which very few escape oblivion, the exact place of his burial was with difficulty discovered, and his remains, found among an accumulation of some two thousand bodies, after a prolonged, difficult, and enthusiastic search, were piously placed at rest with poets and philosophers, "kings and counsellors of the earth." Why should the Dean and Chapter of Westminster, when application was made for a place for Hunter among the honored dead, whose graves they guard, have replied, that "they would be proud to be guardians of the ashes of so great a man?"

Briefly told, the leading facts of his life may be stated as follows: He was born at Long Calderwood, Parish of East Kilbride, Lanarkshire, Scotland, Feb. 13, 1728. The youngest of ten children, as a boy he gave no promise of celebrity. When twenty years old, he was able to read and write his native language; but this was the limit of his scholarship. The fame of his brother William, who is spoken of as "perhaps the best teacher of anatomy that ever lived," proved an incentive to his ambition. In the dissecting-room his progress was wonderful. He studied surgery under Cheseldon at Chelsea Hospital during the summer months of 1749 and 1750. He became House Surgeon of St. George's Hospital in 1756. Ten years' work in the dissecting-room impaired his health, which he sought to regain by acting as surgeon in the army. In 1763, without other pecuniary support than the half-pay to which his army service entitled him, he began practice in London as a surgeon. During the first years of professional life his business allowed him to devote much time to investigations in comparative anatomy and physiology, where he sought for the facts and the principles which are at the foundation of life and health and disease. Nor were these pursuits discontinued while life remained. In 1767 he was elected a Fellow of the Royal Society.

In 1768 he received the appointment of Surgeon at St. George's Hospital, whereby his practice was greatly increased, and pupils, at 500 guineas each, sought his instruction. In 1776 he was appointed Surgeon Extraordinary to the King.

In Dec., 1785, his famous operation for curing aneu-

ism by the application of a ligature between the tumor and the heart was successful.

In 1786 he was appointed Deputy Surgeon-General to the army. The following year he received the Copley medal from the Royal Society.

Thus from step to step he had reached the foremost place in the medical profession; yet we are told that "most of his contemporaries looked upon him as little better than an enthusiast and an innovator."

He died Oct. 16, 1793, of angina pectoris, the symptoms of which are said to have begun twenty years previously. Under date May 11, 1777, he writes to his former pupil, the celebrated Dr. Edward Jenner: "I was taken very ill with a swimming in my head, and could not raise it off the pillow for ten days; it is still not perfectly recovered." This was sixteen years before his death, which came under circumstances of peculiar sadness. While interceding with the trustees of St. George's Hospital for two Scotch students, who were desirous of receiving the educational advantages of that institution, to which there was some objection on account of their imperfect preparation, he was met with rudeness and insult. Without saying a word, he repaired to an adjoining room; a fall was heard, and he was lifeless. Soon his dead body, followed by the empty carriage, was borne to his late home. At the post-mortem examination, it was found "the coronary arteries had their branches which ramify through the heart converted into long tubes, with difficulty divisible by the knife. The mitral valves were *much ossified*. The aorta was somewhat dilated, its valves thickened, and wanting pliancy, and the inner surface of the artery was studded with opaque and elevated white spots."

His greatest gifts to mankind were in connection with surgery. Before his time, surgeons opened the tumor of a popliteal aneurism, and tied the artery above and below it; but many would amputate rather than resort to this discouraging operation, for it seldom succeeded. The principle of applying a ligature between the heart and the tumor, whereby its supply of blood was stopped, its circulation being established through anastomosing vessels, was thus first established by Hunter, and made general by him and his successors.

"Union by the first intention" is a boon which we scarcely appreciate, accustomed as we are to the simple method which Mr. Hunter taught in the treatment of wounds. It would astonish us to see a surgeon stuff a wound with charpie or other foreign substance after amputation, and wait for healing through the tedious process of suppuration and granulation. Yet this was done for many years after Mr. Hunter's death. It was long before the profession learned, what Hunter taught, that two cut surfaces, when brought and held in contact, would speedily unite.

His treatise on the venereal disease was for a long time the standard authority upon this subject. He developed the true principles connected with this disease, and made the treatment scientific, thus putting an end to the empiricism which had previously resulted in disastrous consequences.

An imperishable monument of his career remains in the museum which he founded—the pride of the Royal College of Surgeons. Ten thousand five hundred and sixty-three specimens were a proof of his unceasing diligence when called from his labors. I have mentioned that he did not leave sufficient property to provide for such a burial as his widow desired. The reason may be found in the fact that he had expended £70,000 on this museum alone.

The full and exact value of his labors will never

be known, on account of the destruction of twenty or thirty large folio volumes, written in a fair and regular form, in which he had recorded his observations on comparative anatomy and physiology. They were burned, it is said, by his nephew, Sir Everard Home, who had stolen from them what he afterward published as his own.

I am aware that the subject as presented in this paper contains a very inadequate conception of the achievements of Mr. Hunter. Could an accurate statement of our art as it was in 1763, when he began to practise in London, be made, and his improvements and discoveries be fairly exhibited, it would then be clear how great is the debt which humanity and science owe to his labors—unsurpassed, if not unequalled. The more these are studied and understood, the greater will be the eagerness of physicians visiting the Abbey to find the place where I saw his body laid in the grave; and they will there read, deeply cut in brass, which is inlaid in a slab of polished granite, the inscription: "Beneath are deposited the remains of John Hunter, born at Long Calderwood, Lanarkshire, N.B. on the 13th of February, 1728. Died in London on the 16th of October, 1793. His remains were removed from the Church of St. Martin-in-the-Fields to this Abbey on the 28th of March, 1859. The Royal College of Surgeons of England have placed this tablet over the grave of Hunter to record their admiration of his genius as a gifted interpreter of the Divine power and wisdom at work in the laws of organic life, and their grateful veneration for his services to mankind as the founder of scientific surgery."

MORTALITY AMONG PHYSICIANS IN THE EAST.—At the last meeting of the Relief Committee of "Stafford House," London, some interesting details were furnished concerning the risks run by the physicians who went to Turkey to care for the wounded and sick. This committee has sent 35 physicians to the East; 13 of them were attacked by dangerous maladies, and 2 died. The Red Crescent Society employed 45 physicians, of whom 14 were taken sick, and 7 died. The Red Cross Society employed 14, of whom 3 were taken sick, and 2 died; and the Turkish Charitable Fund sent out 11, of whom 3 have been dangerously ill. Of 40 Sisters of Charity, 30 took the fever, and 13 succumbed to it. Hence, out of a total of 105 physicians, all young and hearty, 33 were attacked with fever, and 10 died of it.

At the International Congress for the relief of the wounded, the Russian delegate made known the losses sustained by the Medical Corps. There were not less than 150 deaths, 14 of them on the field of battle.

MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA.—This Society has recently published the transactions at its last meeting in Weston, May 22, 1878. Some valuable papers were presented at that time.

In the opening address the President, Dr. McSherry, introduced the subject of public hygiene, and Dr. M. S. Hall made a report, urging the importance of the same matter. Papers were read upon the State Insane Asylum and the Medical Botany of Hardy County. There were many very interesting medical and surgical cases reported, the whole making this publication of the Society an extremely useful one.

Before adjourning, the Society elected Dr. W. H. Sharp, President, and Dr. N. F. Hulihan, of Wheeling, Secretary for the coming year.

THE CURVED FLAP IN PLASTIC OPERATIONS ON THE FACE.

By GEORGE F. SHRADY, M.D.,

SURGEON TO THE PRESBYTERIAN AND ST. FRANCIS' HOSPITALS, NEW YORK.

The following case of plastic operation upon the face is presented for the purpose of illustrating what appears to be an improved method of filling a gap in the cheek. Considering the conditions to be fulfilled, it seems to me that no other procedure could have been adopted with a better result. In saying this much for the operation, I can, perhaps, in no more direct way express my appreciation of the good offices of my colleague, Prof. A. C. Post, who suggested to me the form of the flap which was used.

It is always a matter of concern to the surgeon how he can best fill up a vacancy in the face with the least possible deformity. In some instances the patient, far from being benefited, has reason to share the mortification of the operator, and sympathize in the number of scars with the probable condition of the man of "brier-bush" fame. Taking into account the size,

FIG. 1.

and the situation of the tumor removed, and the other conditions which are presented in the following history, it is probably not saying too much to state that the patient was fortunate in escaping with a minimum degree of deformity.

In April, 1877, Alexander M. presented himself at the Presbyterian Hospital, with a small tumor imbedded in the substance of the right cheek. An operation for the removal of this growth, by an incision through the mucous membrane, was performed by Dr. Detmold. Shortly after the operation, however, there was a return of fulness in the cheek, which was accompanied with a feeling of circumscribed hardness, and which finally declared itself as a return of the disease. In the beginning of November the patient again presented himself, the tumor being of the size of a horse-chestnut, occupying its former site, projecting an inch and a half above the facial surface, attached to the anterior edge and external aspect of the masseter muscle, to the maxillary process of the malar bone, and involving the overlying skin, the buccinator muscle, and buccal mucous membrane. It had a hard, almost cartilaginous consistency, espe-

cially over its anterior aspect, where the skin was furrowed and more deeply involved than at any other portion. The entire extent of Steno's duct seemed to be incorporated with the diseased mass.

The operation for the removal of the growth was performed on Monday, Nov. 25th, with the assistance of Drs. Post, Briddon, and Hinton.

An incision was made through the integument along the lower margin of the malar bone forward and slightly downward towards the angle of the mouth. At right angles with this incision, and at either extremity of it, two parallel ones were carried downward and backward, corresponding with the direction of the naso-labial furrow. Lastly, an incision parallel with the first was made, forming a quadrangular space, including the superficial area of the growth.

The incisions were then deepened through the entire thickness of the cheek, and along with the tumor portions of the buccinator muscle and of the mucous membrane were removed, as was also some of the external surface of the masseter muscle. There did not appear to be any direct connection of the tumor with the bone. A good portion of Steno's duct being involved in the growth, was removed with it. The ante-

FIG. 2.

rior edge of the parotid gland showed itself along the line of the posterior incision.

The hemorrhage attending the operation was considerable, but not more than would be expected under the circumstances. A sponge was inserted into the mouth to prevent blood passing into the trachea.

In order to fill the vacant space in the cheek—which was two and a quarter inches in one direction and one and a half inches in the other—a flap was taken from the side of the face and neck. The vertical incisions of the parallelogram were continued directly downward for a distance corresponding with the depth of the vacant space above, and then curved rather abruptly backward until they terminated on the posterior aspect of the neck and behind the ear. This flap thus marked out, and shown in Fig. 1, was separated from the subjacent parts throughout its entire length. Some care was exercised in carrying on the dissection, as it was necessary to follow the external surface of the platysma myoides, and thus avoid wounding the external jugular vein. The flap was then brought up with the greatest ease, and when stitched into place there was not the slightest tension at any

point. As precautionary measures, however, two pin-sutures were inserted in the upper border of the flap and one along the line of the lower curve under the chin. Drainage by horse-hair was established at the most dependent portion of the wound. The pins were removed the second day, as were also the horse-hair drain and the alternate sutures. The wound healed by first intention throughout its entire extent, except in the situation of the drainage openings, which, however, closed within the first week.

The tumor was examined by Dr. Satterthwaite, and was pronounced by him to be an adeno-carcinoma.

On the tenth day after the operation, a small abscess formed between the front of the ear and posterior edge of the flap, and was opened. This continued to discharge for two days.

At the end of two weeks after the operation, the patient left the hospital cured. The openings on the outside had healed, the entire under surface of the flap had solidly united to corresponding portions of the neck and jaw, and the cavity of the buccal surface was filled partly with mucous membrane, and partly with soft, smooth, and pliant cicatricial tissue.

As might have been expected, there was considerable stiffness of the masseter muscle, but this, by the use of wedges between the teeth, has been gradually disappearing, the patient being able to open and close his mouth nearly to the normal extent. Within a week after leaving the hospital he presented himself with an abscess of the cheek, which I opened in the centre of the line of the upper margin of the flap. The discharge was of a character resembling salivary fluid, slightly mixed with pus. I found that the opening which I had left for Steno's duct on the inner side of the cheek was closed. Introducing a probe from the outside to that point, I made a free passage into the mouth. The external opening closed within four days, all signs of inflammation disappeared, and up to the present time the saliva has been discharged freely into the buccal cavity.

The use of the flap with a curved neck, as in this instance, possesses some advantages, in certain cases, over either of the methods ordinarily used by surgeons. These methods are chiefly those which are known as the Italian or Sicilian, which consists in transplanting from remote parts; the Indian, in which the flap is taken from adjacent parts, but the neck of the flap turned on its axis; and the French method, in which the chasm is filled by drawing a flap from the adjacent parts in a direct line.

It is well known that all flaps have a tendency to contract, and that when there is any tension upon the sutures connecting them with the adjacent parts, that union is apt to fail. It is always desirable to give as much margin as possible, in order to guard against such contingencies. The flaps transplanted by the French method show these tendencies to the greatest degree, inasmuch as the line of tension is direct. This necessitates a proportionate increase of length in the dissected skin. The same remark applies in a minor degree to the flap transplanted by the Indian method.

In the flap with a curved neck, however, there is, in proportion to its extent, less tension originally, and less chance for retraction subsequently. The tension, instead of being in straight lines, distributes itself along curves and in the direction of the radii of those curves. Subsequent retraction merely increases the arcs of these curves in a direction to do the least harm. This condition is seen in the alteration of the direction of the latter in Fig. 2, as compared with those made at the time of the operation.

The different directions in which the flap can be stretched, and the facility with which it adapts itself to its new position, is quite surprising, and can hardly be anticipated. In several rehearsals of the operation upon the cadaver I was somewhat disheartened at the degree of redundancy of skin above the lesser curve, and the extent of the vacant space below the line of the lower curve, after the end of the flap was adjusted. Although due allowance was made for the absence of elasticity of skin in the dead subject, I was prepared for the necessity of leaving a small space below the angle of the lower jaw for granulation. I was agreeably disappointed, however, after stitching from the base and extremities of the flap towards the centre, in being able to close up the wound entirely. The stretch was not only along the line of the curves, but in the direction of their radii, and to such an extent in the latter that the redundancy of the tissue under the ear complemented the relative deficiency at the point of greatest convexity of the flap under the jaw.

It is, perhaps, unnecessary to say that the figures represent the appearance of the patient before the operation and at the present time. These are taken from photographs by Mr. O. G. Mason, of Bellevue Hospital. In Fig. 1, are shown the position of the tumor, the quadrangular incision required for its removal, and the shape and extent of the flap. Fig. 2 is intended to represent the patient with the head turned to the right and the chin elevated, thus altering somewhat the relations of the curves of the flap as compared with those in Fig. 1. The scars which remain can be hidden completely by the whisker.

38 EAST THIRTY-SECOND STREET, N. Y.

Reports of Hospitals.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SERVICE OF CHARLES T. HUNTER, M.D.,

DEMONSTRATOR OF SURGERY IN THE MEDICAL SCHOOL.

(Reported for THE MEDICAL RECORD.)

FOREIGN BODY IN THE URETHRA.

On the 17th of July, 1878, T. D., *et. 63*, was admitted into the University Hospital, for the purpose of having a fragment of a glass tube extracted from his urethra. D. gave the following history of his case: Has always been strictly temperate in his habits; and has never had any affection of his genito-urinary apparatus.

For several years patient has been one of a relief committee of a lodge of "Knights of Pythias," and while performing the duties of this position he met several members of this order who had great difficulty in passing urine, in consequence of enlargement of the prostate gland, and were dependent on the use of a catheter for relief. Fearing that he might have the same trouble at some future time, and being anxious to provide against such a disagreeable contingency, T. D. determined to practise catheterization on himself with a glass tube. In his first attempt he succeeded in passing a medium-sized glass tube into his bladder, and drew off urine, without the parts involved sustaining any injury. The success of this experiment encouraged him to try the operation a second time, the results of which were less satisfactory, as the sequel will show. On the day of T. D.'s admission into the hospital, he procured a straight

glass tube, about 25 centimetres (10½ inches) in length, and half a centimetre in diameter, with which he proposed to repeat self-catheterization. He had no difficulty in introducing the tube as far as the prostatic urethra, but at this portion of the urethra the tube was suddenly arrested. D., in his efforts to overcome the obstruction, used sufficient force to break the tube in two pieces, one of which he immediately pulled out of the urethra, but the other being out of his reach, was left in. Shortly after D.'s admission to the hospital, I made an examination, and found the fragment of the glass tube fixed in the urethra, one end in the prostatic portion, and the other penetrating the wall of the scrotal part. The fractured end of the fragment, D. had forced through the floor of the urethra into the loose cellular tissue of the scrotum, by his attempts to get the tube out. He had also tried to expel the tube by passing his urine; but instead of displacing it, it only served to carry urine into the scrotum, through the cellular tissue of which the urine was quickly diffused. From the position in which the foreign body lay in the urethra, and the manner in which it was held there, it was evident that it could not very easily be extracted by any instrument, such as forceps, passed into the urethra. Nor could it be removed through an opening made in the perineum without risk of doing additional violence to the already lacerated urethral walls. To take it out through a perineal section would necessitate the breaking of the fragment of tube in two or more pieces in the urethra; and the removal of which pieces would be attended with considerable danger, in consequence of the sharp, angular ends which the pieces would have. In considering the difficulties of the case from all points, it occurred to me that, in consequence of the fractured end of the broken tube being already in the scrotum, the safest and the most practicable plan of removing the tube would be, either to make an opening in the integuments of the scrotum, and extract the tube through it, or to introduce my finger into the patient's rectum, get behind the smooth end of the tube in the prostatic urethra, if possible, and push the sharp end forward through the scrotal walls. As soon as the patient had been brought under the influence of ether, I directed two assistants to support his legs in the position that they would be held in the operation of lithotomy, in order that the scrotum and perineum might be fully exposed.

I now proceeded to introduce my right forefinger into the patient's rectum, carried it up behind the prostate gland, till I could distinctly feel the smooth end of the tube through the urethral wall; then, having made the scrotal integument tense near the fractured end, with the thumb and finger of my left hand, I quickly pushed the tube forward through the scrotal wall with my right forefinger. The small wound of the scrotum, made by the operation, was instantly closed by contraction of the dartos structure. As the scrotum had become infiltrated with urine prior to the extraction of the tube, I made four free incisions in it, two either side of the raphé, to relieve tension and to get rid of the urine, thereby to prevent subsequent sloughing. For eight days after the operation the patient's urine was drawn off three or four times a day with a catheter, the utmost care being used to prevent the escape of any urine through the wound in the urethra. At the expiration of this period he was permitted to pass his urine in the natural way; this he was able to do freely and without pain, clearly showing that the wound of the urethra had securely healed. Apparently, as a consequence of

some injury inflicted on one of the testicles by the end of the tube, a mild epididymitis developed itself soon after the accident; this attack, however, yielded promptly to treatment, and soon subsided. The incised wounds of the scrotum that were made to facilitate the escape of urine from the cellular tissue, healed in a short time under the effects of local applications of laudanum and water. The patient's bowels were kept at rest for four or five days, and some slight pain relieved by suppositories of opium; no subsequent medication was required.

In the progress of this case it is worthy of notice that the patient did not have either a chill, or any symptoms of urethral fever. On the 30th of July D. left the hospital quite well, with the exception of a little enlargement of one epididymis. The length of the fragment that was extracted was 10½ centimetres (about 4½ inches).

Progress of Medical Science.

INTESTINAL STENOSIS AS A RESULT OF TUBERCULAR ULCERS.—A woman, 42 years of age, was admitted into the Vienna General Hospital with a history of having suffered for ten years from paroxysmal attacks of gastric pains, accompanied by vomiting and loss of appetite. During the preceding five weeks she had suffered also from abdominal pains, with alternating diarrhoea and obstipation. When admitted she was very emaciated and anæmic. The abdomen was very tender on pressure, especially in the epigastrium and above the symphysis. Vaginal examination showed that the end of the vagina and the uterus were very sensitive. No abdominal tumor could be discovered. The paroxysms of pain were accompanied by loud rumbling and colicky contractions in the intestines. The examination of the lungs and other organs was negative. The evacuations were often very profuse and fluid—partly fecal and partly mucous, grayish or yellowish. They were generally followed by relief of the abdominal pains. These diarrhoeal passages alternated with obstipation. Old grape seeds were frequently found in the evacuations, although the patient had eaten no grapes during the preceding year. This circumstance pointed strongly to the existence of an intestinal stenosis. One obscure point in the clinical history was the very frequent occurrence of high fever (104° F.) at night, followed by profuse sweating. Quinine had very little effect on these attacks of fever. They naturally aroused a suspicion of tuberculosis, but the examination of the lungs revealed nothing abnormal, and there was absolutely no cough or expectoration. Four months after admission to the hospital salivation set in, without any affection of the mouth. These symptoms persisted for eight months, when the patient died of exhaustion.

The section revealed groups of gray and yellow nodules and spots of caseous hepatization scattered throughout the upper lobes of both lungs; slight swelling of the gastric mucous membrane. About the junction of the jejunum and the ileum a short stretch of the intestine was twisted in various directions by false membranes and adhesions, and was bound fast to the abdominal wall in the neighborhood of the internal inguinal opening. At the point of adhesion the intestine, the lumen of which was already diminished by the twisting, was still further constricted by a wide, ring-shaped ulcer with a slate-

gray callous base containing yellow, cheesy masses. The uterus was enlarged and dense; the tubes were distended and filled with cheesy masses.—*Bericht der k. k. Rudolph-Stiftung in Wien, 1877.*

ACUTE ASCENDING PARALYSIS.—Dr. Jaffé reports a case of the rare form of disease known as acute ascending paralysis (Landry's paralysis). The patient was a young man, 25 years of age, with an excellent family history, and came under observation on October 2, 1877. He had contracted a syphilitic ulcer nine months previously, followed by secondary roseola, and he had indulged very much in venery for a few weeks previous to the onset of his present illness. August 31, 1877, the patient began to suffer from diarrhoea, debility, and a feeling of heaviness in the legs, which had increased to such an extent by October 2d that he was unable to leave his bed.

Present condition, October 2d: Pulse and temperature normal; lower limbs completely paralyzed; reflex action lost; sensibility perfect. Upper limbs are normal. In the course of the day patient complained of a painful pressure upon the chest. October 3d: Diarrhoea has ceased after the administration of opium. The nerves and muscles react normally to the induced current. The hands have become paretic. October 4th: Paresis of upper limbs has increased to such an extent that the patient is unable to feed himself. No urine was passed for the last twelve hours. Temperature still normal. The paralytic symptoms increased in intensity for the next three days; retention of urine still persisted; respiratory movements were very superficial. The faradic excitability of the paralyzed parts had markedly diminished, but slight galvanic excitability still persisted. Sensation and cerebral functions normal. Tendon reflex could not be obtained. The muscles contracted readily upon slight percussion. There was no atrophy of the limbs. The patient was placed under antisyphilitic remedies. Symptoms remained the same until October 12th, when dyspnoea set in, in consequence of acute pulmonary oedema, and the patient died in a few hours. This case is differentiated from poliomyelitis anterior acuta by the ascending character of the paralysis, by the absence of atrophy of the muscles, and by the absence of degenerative reaction. This observation disproves the opinion that the electrical excitability of the paralyzed nerves and muscles is always retained in this disease. Unfortunately, no post-mortem could be obtained.—*Berl. Min. Wschrft., November 4, 1878.*

TREPHINING IN EPILEPSY.—In the *Archives Gériatriques de Médecine* for December, 1878, Dr. Echeverria has published a *résumé* of the results of trephining in epilepsy resulting from injuries of the skull. He has collected 145 cases of this operation. Of these, ninety-three were followed by recovery; eighteen by improvement; in five no change was produced; one was rendered worse; and death resulted in twenty-eight cases. The causes of death, in the fatal cases, were extremely varied, viz.: suppuration over the whole surface of the brain, hemorrhage into the brain under the seat of operation; gangrene of the membranes and cerebral abscess; obstinate hemorrhage of the superior longitudinal sinus; meningitis and meningo-encephalitis.

Dr. Echeverria gives the following *résumé* of the results of his analysis of the cases referred to:

Trepanation is the best means which can be employed in the treatment of epilepsy caused by injuries to the skull.

The immediate operation appears to be almost as

successful as the late; fever forms a serious contra-indication to the operation. Insanity and paralysis justify the operation.

Trephining succeeds equally well when syphilitic products upon the bones of the skull, and which have proved rebellious to specific treatment, act as the cause of epilepsy.

The success of the operation depends, in great part, upon our ability to prevent irritation of the cerebral meninges.

It is, finally, advisable to keep the patient under anti-epileptic treatment for some time after the operation, in order to overcome the so-called epileptic habit of the nervous system.

RARE CASES OF LARYNGEAL PARALYSIS.—Dr. G. M. Lefferts has published, in the last number of the *New York Medical Journal*, two extremely interesting cases of bilateral paralysis of the dilator muscles of the glottis (musculi erico-arytenoidei postici), in both of which recovery occurred. The first patient was a woman, æt. 40 years, who had previously suffered from secondary and tertiary manifestations of syphilis. At the end of April, 1876, she began to suffer from continually increasing dyspnoea, and on May 7th had two severe attacks of laryngeal spasm. Inspiration was attended with stridor and considerable muscular effort; expiration was noiseless, easy, and short. The voice was but slightly husky. On laryngoscopic examination, a narrow slit was seen between the vocal cords, gaping slightly during expiration, and *disappearing entirely* on forced inspiration. The sensibility of the laryngeal mucous membrane was undiminished. The patient was placed under antisyphilitic remedies, and on June 15th laryngoscopic examination showed normal condition of the glottis, all the dyspnoeal symptoms having likewise disappeared.

The second case reported by Dr. Lefferts was, in all respects, the same as the first. It occurred in a syphilitic female patient, and rapidly improved under antisyphilitic measures. Apropos of the first observation, Dr. Lefferts expresses the opinion that, in the absence of corroborative evidence of any specific lesion in the nervous centres, he must regard the paralysis of the muscles as due to some direct and local effect of the syphilitic virus, although what the nature of this action is, he is unprepared to state. This hypothesis does not appear to be supported by any positive evidence in its favor.

LYMPHATIC ELEPHANTIASIS ARABUM.—The results of a post-mortem examination of a fatal case of lymphatic enlargement of the thigh and leg were reported by Dr. Day, of London, to the London Pathological Society. They were principally negative, for which Dr. Day accounted by our very limited knowledge of the physiology and the pathology of the lymphatic system. There was no evidence from this examination of any obstruction to the femoral vein, and, apparently, no enlargement of the arterial or venous trunks, though it seemed highly probable that some great disturbance took place from time to time, owing to the heat of the limb, pain and swelling, and especially those rapid local changes in the limb which ensued shortly after the fatal seizure. There was an increased length and growth of the bones of the affected limb, in which this case differs from all the cases of which Dr. Day has any knowledge, although a similar one is said to have been reported by Dujardin in 1854.—*Chicago Medical Journal and Examiner, December, 1878.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, January 25, 1879.

PROFESSIONAL ATHLETES AND PHYSICAL EXHAUSTION.

PUBLIC attention has been directed, particularly within the past few months, to various extraordinary feats of pedestrianism and wrestling. As might have been anticipated, the interest has been carried to that extreme of absurdity which has culminated in betting upon the endurance of human beings the same as upon that of horses or other beasts. The consequence has been that, instead of elevating healthful exercise in the estimation of the people, athletes are found who are willing to prostitute their powers and cater to a morbid appetite by testing their strength, even to the jeopardy of life itself. Fatigue takes the place of natural reaction, and exhaustion means victory.

Not long since a lady completed a walk in Brooklyn, apparently for the purpose of proving how much severe work she could undergo, and from how much sleep she could deprive herself in the meantime. At the end of the trial we hear of her victory coupled with the apparently unimportant statement that she was thoroughly exhausted, and had delivered herself up for medical treatment. It is also stated that the greatest care has to be taken to return her to her previously normal condition, in order that she may not suffer from the dreadful reaction which outraged nature inflicts. And this history does not stand alone in the records of pedestrianism or wrestling-matches. Not long since an athlete was carried from the ring fainting, with weak cardiac pulsations, and in a general state of prostration, which prospected permanent disability. The heart-strain of soldiers during forced marches, of oarsmen in a hotly contested race, of gymnasts in a vaulting-match, are accidents which are acknowledged to be of quite frequent occurrence, but are seemingly entirely lost sight of in the desire for a victory, the expenditures of strength and of vitality in which could at any time be surpassed by many of the lower grade of animals.

A few days since it was announced that a wrestler in Chicago sustained a fracture of the clavicle, by being heavily thrown during a performance. Of course this was legitimate, and the suffering man was defeated. But how can all these things prove that professional athleticism is a useful science, and that its study from such a standpoint should be encouraged with the American people?

We are accustomed to advise our patients that exercise beyond the point of fatigue is detrimental; what can we say for the benefit of such exercise when it approaches the verge of absolute exhaustion?

SCHOOL HYGIENE.

In a recent number of *Puck* a very suggestive cartoon bearing upon school hygiene is presented. A class of infants with enormous heads and attenuated frames worn out by exhaustion are being taught by a skeleton who, in his blackboard definitions of grammar and geography, etc., makes some capital hits on the prevailing school diseases. Between him and the scholars is an open sewer-trough, the poisonous vapor from which obscures the map upon the wall and causes a member of the Board of Education, who, oddly enough, is on a tour of inspection, to hold his nose. Sketches like these are exceedingly effective, and no cause like the one which is at present being plead is more worthy the advocacy of the gifted pencil. Too much pains cannot be taken to bring the matter before the people in the way of compelling a proper reform.

In connection with the latter point, it is a subject for great congratulation that the Board of Education has at last been so effectually aroused by the press, that steps have been taken to inquire, by means of a committee appointed for the purpose, into the sanitary condition of the schools. As an evidence of their earnestness in the matter it may be stated that when one of the Board chose to insult the gentlemen of the press and other parties, by attributing to them interested motives in regard to the matter, the other members apologized for him and wished to place their protest on record. We shall watch the doings of the committee with much interest.

MEETINGS AND TRANSACTIONS OF THE STATE MEDICAL SOCIETY.

WE are glad to receive from Dr. Smith, the present Secretary of the State Society, a letter (in another column) which appears to throw some color of legality about the change in the meeting time of the Society in 1876, and also affords confirmation of the rumor, to which we had previously alluded, that there had indeed been a meeting of the State Society in February of that year, the minutes and proceedings of which meeting, however, have never appeared in the published Transactions of the Society. Concerning this meeting, Dr. Smith says: "They had therefore

full authority to adjourn this annual meeting to June, 1876." The Transactions, however, do not speak of the June meeting as an adjourned, but as "The Annual Meeting held pursuant to statute." It, as suggested by Dr. Smith, the change February 1, 1876, was made in accordance with the provisions of the Act of 1823, it will be interesting to learn whether this actually took place before or after the passage of the statute of February 1, 1876. It is certainly a little curious, moreover, that the twenty-three members of the State Society then assembled in Albany knew nothing of the legislation affecting their interests, which on that very day became law, and it is still more curious that none of the officers of the State Society appeared to know of the existence of this statute, until more than eighteen months after its enactment. We presume the true state of affairs, however, may be arrived at when the omitted minutes are published. It is but justice to Dr. Smith to state that the matters here referred to occurred before he became Secretary, since which time the Transactions appear to contain the full and entire proceedings of the Society.

There are some other facts, however, connected with the Transactions that should receive consideration. For many years, up to and including 1874, the Transactions were published at the expense of the State, and copies of them were distributed to the county societies, whose members received them either free or on payment of a nominal sum. Some years ago, at one of the annual meetings of the New York County Society, a cart-load, more or less, of these Transactions was brought to the meeting, and the members were informed that they could have them gratis, if they would give themselves the trouble of taking them away. A few members availed themselves of the opportunity, but the remainder of these volumes still remain in the possession of the Society. Since 1874, the Transactions have been published nominally at the expense of the State Society, but virtually at the expense of the county societies, which are compelled to subscribe for five times as many copies as they have delegates, under the supposition that their members would gladly take them at the price fixed by the State Society.

As each fresh invoice was received, notice was duly given by the Secretary to the members of the Society, that the Transactions had arrived and could be obtained from him at cost price. As a matter of fact, but few copies were sold in this way, and at the last annual meeting the Secretary stated that there were still some five or six hundred volumes in the possession of the Society, and that more were coming. After some discussion a motion prevailed to dispose of them to members at the rate of fifty cents a volume. Of this resolution all members were officially informed by the Secretary. The rush for the Transactions at the reduced price did not exhaust the supply. In fact

we are informed that not more than a dozen applications were received. At the last meeting of the Society it was voted to distribute them gratis to such members as would call on the Secretary for them. It remains to be seen how much this offer will reduce the stock on hand. It is certainly very clear that the members of the New York County Society do not want the volumes at the price which the Society has to pay for them, and under these circumstances the Society may well consider whether it is to its interest any longer to encourage the publication of volumes whose value to them does not appear to be equal to the cost of production.

THE ALCOHOL QUESTION IN ENGLAND.

WITHIN a comparatively recent time serious attempts at temperance reform have been begun in England. Many prominent persons have interested themselves in the agitation, which has shown itself in the organization of coffee-house companies, in the securing of pledges, and in demands for new legislation. The idea of drinking only water is a novel one to the English mind, but the energetic efforts of the reformers have at length brought it into prominence. There has recently appeared in the *Contemporary Review* a kind of "symposium" on the alcoholic question, the contributors being seven English physicians, most of whose names are familiar. Some idea of what their opinions are may not be uninteresting.

Sir James Paget takes the ground that the moderate habitual use of alcohol is "certainly pleasant and probably useful." In regard to moderate drinking, he says that the balance of medical and of popular feeling favors it, and that neither statistics nor physiological or pathological researches have proved it injurious. Nations who use alcohol largely, compare well with those who do not use it, and they do not appear to have inherited evils from their many generations of drinking ancestors.

Dr. T. Lauder Brunton takes up the more practical side of the question, discussing how and when alcohol is useful. There is, he says, a small class to whom alcohol is a poison; the smallest amount sets them wild. There is a second class whom alcohol exhilarates and quickens for the time; such persons indulge in it at great risk. The great majority of persons under middle age do not need it, and, as a rule, are better without it. In persons who are in the decline of life, however, and in the debilitated, alcohol is a powerful and beneficial remedy. Alcohol is given as a food and as a stimulant. It is a food, but is one which interferes with the oxydation of other foods in the body while it is being itself decomposed, and as a food it is only adapted to feeble conditions. As a stimulant it acts directly upon the heart, and reflexly upon the stomach, stimulating the circulation of the brain. After the first stimulus to the nervous system, the succeeding effect of alcohol is one of pro-

gressive paralysis. The higher centres suffer first, notably the judgment, and finally all succumb. Alcohol as a stimulant is useful occasionally to tide over a severe crisis, but its best effect is in rousing the system at the close of exhausting work.

Dr. Albert J. Bernays believes in the moderate use of alcohol also. He dwells more especially on the causes and extenuating circumstances of intemperance. In regard to these, he says that the water furnished by London, to its lower classes at least, is extremely bad and undrinkable. Then the adulterations in beer make its effect worse. Sugar is put in, and this destroys its thirst-quenching property, and salt acts in the same way; these being the two important adulterations. The variations in the alcoholic strength of liquors increase intemperance. At present, gin may have all the way from fifty-four to eighty per cent. of alcohol in it. The atmosphere of public-houses is foul and overheated, and is injurious to the workingmen who sit there. Beer is the best form of alcoholic drink according to Dr. Bernays, and wine the next. The present intemperance cannot be corrected by teetotalism, but it can be alleviated by other methods.

Dr. Walter Moxon takes ground against total abstinence, but devotes most of his article to a psychological explanation of why a man becomes a sot. His analysis of the question is sufficiently profound and correct, but it only tells us in polysyllabic terms that the nervous, excitable temperaments are more susceptible to alcohol than the phlegmatic ones.

Dr. S. Wilkes asserts alcohol to be, to all intents and purposes, a narcotic and not a stimulant. It does not help those who are under special mental pressure, such as students working for prizes. It makes those engaged in intellectual effort less clear-headed, and under its influence the English laborer does less work.

Sir Wm. Gull is more careful in his recommendations of alcohol. In disease and debility it is useful, and also in overwork; but in the latter instance other things will do just as well, and Gull himself, when exhausted, eats raisins instead of drinking wine. Good food will supply all the wants of the system up to middle life, and though a glass of beer may help a laborer along, a biscuit will do just as well. Intellectual work can be done better without the alcohol. Bitter tonics or Liebig's extract of meat may quiet the craving for liquor which many persons have at times.

Dr. C. Murchison states that a man in good health does not need alcohol, and is probably better without it. He may take liquor occasionally without harm, but its habitual use, even in moderation, is attended with risk and may even induce disease. In conditions of the system characterized by weakness of the circulation, the habitual daily use of alcohol is likely to be beneficial.

It will be seen that in general these views coincide

with those of the profession at large. Alcohol in disease is a valuable remedy; in the decline of life it is a useful adjunct to the diet; in healthy persons who have been overworked, it helps recuperation; its habitual use is always attended with risk.

As regards total abstinence, we believe it to be unattainable, and, except for the young and healthy, undesirable. There is an appetite for alcohol which will be satisfied, and which neither temperance societies nor legislatures can destroy. It would be better, then, if the spasmodic efforts of these bodies to prevent the use of alcohol altogether were directed to seeing that it is used temperately. There is much to be done in the way of introducing good malt liquors and light wines, in establishing coffee-houses, and in introducing harmless substitutes for alcohol. It might be of help if physicians would impress the fact that alcohol is essentially a narcotic, not a stimulant. And something might be accomplished by educating every one, not omitting the higher classes, to a deeper sense of the beastliness of inebriety.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 11, 1878.

DR. JOHN C. PETERS, PRESIDENT, IN THE CHAIR.

ADENO-CARCINOMA OF CHEEK—PLASTIC OPERATION.

DR. GEO. F. SHRADY presented a tumor of the cheek, which he removed Nov. 25th from a male patient aged forty-three years. The specimen was not so interesting from a pathological as from a surgical point of view; in fact, the principal object of its presentation was to illustrate a somewhat novel method of filling up a vacancy which was occasioned by the operation. (*Vid.* page 82.)

DR. POST remarked that the use of the flap with a curved neck in that situation was a novelty, and the very satisfactory result of the operation showed its superiority over the ordinary straight flap which is generally advised.

DR. HOWE did not see the necessity for horse-hair drainage in Dr. Shrady's case. He believed that the wound would have healed entirely without it; as it was, the only part that did not unite was in the track of the drain.

DR. SHRADY remarked that the horse-hair drain was introduced as a precautionary measure, and was allowed to remain only twenty-four hours, giving exit to the bloody serum, which might otherwise interfere with primary union at other points.

DR. POST thought in all such cases it was best to be on the safe side, as there was generally some oozing of serum under the flap. If this matter accumulated it might produce an abscess which would necessitate the tearing open of some part of the original wound, or the making of a new opening.

AN INTERESTING CASE OF OMENTAL HERNIA.

DR. ALFRED C. POST presented a specimen of omentum with the following history:

On the 3d December, 1878, I was called to Jersey

City, in consultation with Drs. Quimby and Kiersten, Jr., to see Mrs. —, *ætat.* 37, who had had what was supposed to be a reducible inguinal hernia for about twelve years, and had worn a truss for the same. Six days before I was called in consultation the hernia was represented to have come down, and she could not replace it. The swelling became hard, indamed, painful, and tender on pressure. The bowels had been somewhat constipated, but enemata had brought away some fecal evacuations. There had been some vomiting, but not of a stercoraceous character. Leeches had been applied, with partial relief of the pain. I found a hard swelling of an ovoidal form just above Poupart's ligament, extending from the pubes nearly to the anterior superior spinous process of the ileum, but not descending into the labium. There was no resonance on percussion. The patient being etherized, an attempt at reduction was made, but without success. There was considerable uncertainty as to the diagnosis of the disease—the form, the position, and the firmness of the swelling seeming to indicate the existence of an inflamed lymphatic gland, while the clinical history rendered probable the existence of a hernia. It was determined to make an incision down to the diseased structure, and to do whatever the circumstances of the case seemed to require. Dr. Quimby accordingly cut down on the tumor above Poupart's ligament and parallel with it, and cautiously divided layer by layer, until a sac was opened, from which there was an escape of an ounce or more of bloody serum. There was no intestine in the sac, but a mass of omentum, intensely congested, of a very dark color like that of venous blood, but not softened in its texture nor emitting a gangrenous odor. This was very carefully unfolded to ascertain that no portion of intestine was concealed within it, and being deemed unfit to be returned within the abdomen, was excised with scissors close to the external ring. After this a free application of carbolic acid (1 to 40) was made to the stump, which was then carried upon the finger into the abdominal cavity. The wound was then thoroughly sponged with the same carbolic solution, and tents moistened with the same were introduced into the sac and into the wound outside of the sac. The edges of the wound were then closed with fine sutures, except at the end where the tents protruded. Linen cloths, wet with the carbolic solution, were then applied over the wound, and directed to be covered with oil-silk.

On the 7th December, Dr. Quimby reported that the patient had suffered considerable pain on the day after the operation, but that relief had been afforded by an eighth of a grain of sulphate of morphia every hour. The patient had since done well.

THE DIAGNOSIS OF STRANGULATED HERNIA.

Dr. BRIDGON referred to the case of a German woman, upon whom he had operated for strangulated hernia, many years ago. The patient had been treated by an apothecary for six or seven days for inflammation of the bowels. She then fell into the hands of Dr. Aigner, who asked Dr. B. to see her. The history of the case was one of incomplete obstruction. There was vomiting, but it was not stercoraceous in character. The parts presented precisely the character of a suppurating bubo. The centre of the swelling was traversed by Poupart's ligament, and the periphery of the swelling was œdematous. An incision down upon the sac gave exit to a considerable quantity of fetid serum. The gut was of a dark maroon color, but was not gangrenous. After the stricture was divided the gut was returned. The

patient made a good recovery. On the ninth day after the operation, she, considering it a critical period, took an ounce of cream of tartar, which insured for her a good passage, not only per rectum, but through the wound. The wound subsequently healed.

A second case, to which he also referred in this connection, was that of an Italian woman whom he saw with Dr. Walter Gillette. This patient had also the symptoms of partial intestinal obstruction, viz., vomiting, but not stercoraceous in character. A swelling extended on the right side from the spine of the pubes to the anterior superior spinous process of the ilium. It was impossible to distinguish the character of the hernia because, as in the former case, the tissues were infiltrated, the parts were immovable, and the skin was œdematous, as in abscess. An incision being made, he came down upon a cavity containing pus which was apparently in the intestine itself. The neck of the sac was situated external to the femoral artery after having passed underneath the ligament. At the bottom of the cavity laid open was a structure lying under the mucous membrane, which he supposed to be the appendix vermiformis. Whether it was a case of hernia of the cæcum or not, he was not prepared to say. Fæcal matter was discharged from the wound for some time, and then everything closed up.

A third case, bearing upon the question of the diagnosis between swollen lymphatic glands and hernia, was also recited. He was called, two or three years ago, to see the son of a physician, who was said to be suffering from the symptoms of strangulated hernia. The little patient was six years of age. He presented a swelling in his groin, immediately over the saphenous opening, and about the size of a hickory-nut. It was movable, gave no pain, and there was no vomiting. Dr. B. felt quite sure that there was no hernia, but an abscess. The father of the child assured him, however, that there was no swelling in the groin an hour before. With the assistance of Dr. Mason, who was called in counsel, an explorative incision was made over the swelling. On dividing the superficial fascia, the resemblance of the appearance to that of hernia was very marked, as the swelling was underneath the cribriform fascia that covered the saphenous opening. The incision was continued through the fascia, when an inguinal gland as large as a hickory-nut was turned out, and that was the end of the hernia.

Dr. MASON remarked that in the latter case there was vomiting and tenderness on deep pressure over Poupart's ligament.

Dr. BRIDGON did not recollect that point in the case.

Dr. Post had met with vomiting and abdominal pain associated with inflamed glands, especially if the latter were situated beneath the deep fascia.

SCIRRHUS OF BREAST.

Dr. Post also presented a specimen of scirrhus of the breast, with the following history:

Mrs. O'B., *ætat.* 65; admitted into the Presbyterian Hospital November 18, 1878. She had been married forty-five years, and had had no children. She noticed a tumor in the breast about five months before her admission. The tumor involved less than half of the substance of the gland. The nipple was retracted, but the skin moved freely over the breast, and the breast was free from any adhesion to the subjacent parts. The lymphatic glands were not apparently involved in the disease.

On the 21st November I excised the breast in the usual manner, removing with it a strip of integument about two inches wide, including the nipple. There was very little hemorrhage, and only two vessels were

tied. I did not use antiseptics until after the removal of the tumor, when I washed the whole surface of the wound with a carbolic solution (1 to 40), and introduced a drainage-tube through the whole length of the wound, projecting at the two extremities. I then closed the wound with numerous fine sutures, after which the carbolic solution was injected through the drainage-tube. The wound was then covered with lint moistened with the carbolic solution, over which oil-silk was applied. No bandage was applied over the dressings. Within about a week the sutures and the drainage-tube were removed, and union had taken place throughout nearly the whole of the wound.

I have performed excision of the mammary gland at the hospital in two other cases within the last two months, and employed similar dressings, with like results. In one of these cases, a male patient, whose general health was much impaired, a portion of the wound reopened, and has been tardy in healing.

EXCISION OF KNEE-JOINT.

DR. E. MASON presented the knee-joint which he had excised from a patient of Bellevue Hospital on the 25th of last September. The patient, who was also exhibited, was thirty-six years of age, married, and a laborer by occupation. About six months before admission to the hospital he injured his knee by a stroke from an axe. The wound was a superficial one, and healed in three days, when he returned to his work, that of a miner. In the course of a few days afterwards the thigh became swollen and painful. A surgeon made an incision on the inner side of the knee, and, according to the patient's statement, a pearly colored fluid escaped. This wound continued open. Shortly after the incision an abscess discharged itself on the outer side of the knee, and at the bottom of the sinus, which was still open, bare bone was detected. Three months before admission a spontaneous opening appeared below the tubercle of the tibia. The leg was flexed upon the thigh at an angle of 160°, the joint was fixed, and the head of the tibia dislocated backward. On examining the patient it was supposed by some of the surgeons that bony ankylosis existed. Through the opening on the inner side of the head of the tibia a probe could be passed into the cavity of the joint. When the patient was placed under ether, motion of the joint could be obtained, and bony crepitus could be elicited.

It was evident that the whole joint was completely disorganized. The ends of the articular surfaces were sawn off, the extremities of the bones wired together, a drainage-tube was introduced, and the limb put up in an immovable plaster apparatus. The operation as well as the dressings for some weeks afterwards were done under carbolic spray. The patient did remarkably well. At no time, with one exception, did his temperature rise above 100° F. At the end of the first week the wound had healed except in the line of the horse-hair drain. The latter was removed at the end of the second or third week, and all the apparatus was removed. At the end of six weeks the silver wire was withdrawn and firm bony union was found to have taken place. Since that time the patient had been walking around the ward with the aid of a cane.

Stated Meeting, December 26, 1878.

DR. JOHN C. PETERS, PRESIDENT, IN THE CHAIR.

RHINOPLASTY.

DR. A. C. POST presented two photographs illustrating the appearances before and after the operation for

rhinoplasty. In the month of June last, a male, aged eighteen years, presented himself for treatment at the Presbyterian Hospital, with a deformity of the nose, occasioned by the kick of a horse ten years before.

The nasal bones had been fractured and driven down almost to a level with the facial plane, while the top of the nose was turned strongly upward, the nostrils presenting themselves anteriorly.

The operation consisted in making an incision from cheek to cheek, through the nasal pyramid, and about three-quarters of an inch from the tip of the nose. The nasal septum was divided and the tip brought down to its proper relation, the vacancy occasioned thereby being filled by a flap from the forehead. Several minor operations were performed subsequently, resulting in a well-formed nose.

DR. POST stated that DR. WEIR performed a similar operation upon a patient with an upturned nose, but took the flap for filling the chasm from the side of the cheek.

RAPID LITHOTRITY

DR. SANDS presented a vesical calculus which he had removed by Bigelow's operation of rapid lithotripsy. The patient was a gentleman sixty-nine years of age, of delicate constitution, and who had suffered for a long time from lung trouble supposed to be chronic phthisis, and who had at the time he came under observation slight albuminuria, the urine also containing hyaline casts. Symptoms of stone showed themselves two years before the operation, and during the summer of this year he was examined by a gentleman of this city, who referred him to Dr. SANDS. Dr. S. saw the patient in consultation with Dr. DELLART, at Chappaqua, and performed the operation on the 28th of October last. The urine contained a moderate amount of pus and triple phosphate. Although it had been noticed at previous examinations that uric acid was contained in the urine, it was believed that the stone was hard. So it proved to be. The operation lasted one hour and ten minutes. The fenestrated lithotrite was used. The aspirator was employed twice only. The first time the fragments were removed, the second time the bladder was thoroughly emptied. The prostate was enlarged. The urethra was capacious and would have admitted a larger tube than the one employed. The size used was No. 28, and was a curved one, the straight tube having failed to enter. The stone was found to consist of uric acid. It measured in diameter one and a quarter inches. It was pretty thoroughly crushed before the aspirator was used. When the tube was inserted the first gush of urine carried with it a considerable quantity of detritus, which was not collected. The fragments which were obtained weighed ninety grains. The patient had no bad symptoms after the operation. In the third week he was able to get out of the house, and within a month walked two miles and a half without discomfort.

In conclusion, Dr. SANDS remarked that Bigelow's method was a decided improvement upon the old one, and that the apparatus devised by Dr. B. embodied so many important improvements of Clover's apparatus that it was virtually a new departure.

DR. POST, while not wishing to detract from any merit belonging to Bigelow's method, wished to state that he had operated in a number of cases successfully by the old plan, and under what *a priori* might have appeared to be great disadvantages. One patient came during the winter months (to Dr. POST's clinic) from Yonkers, a distance of eighteen miles, and returned after each sitting. There were four of the latter, which were necessarily quite prolonged. No un-

pleasant symptoms followed. In that instance the stone which was crushed was of moderate size. When stones were large, the advantages of Bigelow's method over all others were not to be questioned.

THE PATHOLOGY OF NEPHRITIS.

DR. C. HEITZMANN exhibited microscopic specimens of inflamed kidneys. The process of acute nephritis has been studied in his laboratory by Dr. Alfred Meyer, and the results published in the Transactions of the Imp. Acad. of Sciences of Vienna, Vol. LXXV., 1877. Since Richard Bright, in 1827, has drawn attention to diseases of the kidneys very often fatal—the term "Bright's Disease" was extensively used, although it was evident that quite a number of different morbid processes of the kidneys were included in that term. In fact, no scientist should use the expression "Bright's Disease" nowadays, but rather designate the main series of diseases as inflammatory, viz., nephritis. Against the views of Virchow, who distinguishes an interstitial and parenchymatous nephritis, the older denominations of 1. Catarrhal, 2. Croupous, and 3. Suppurative Nephritis, deserve preference, according to the researches of the named author.

1. In acute catarrhal nephritis the epithelia of the tubules are much enlarged, so as to reduce the central lumen considerably; they are coarsely granular, viz., their living matter is augmented, the interstitial connective tissue exhibits the condition of oedema and of beginning inflammatory infiltration. This disease in its highest degrees kills rapidly with the symptoms of uræmia, milder degrees lead to desquamation of the epithelia; these appear in the urine together with a varying amount of albumen, but without tube-casts. In the chronic condition the interstitial connective tissue is reduced to inflammatory or embryonal elements, from which, in turn, new cicatricial connective tissue arises. In the production of this tissue also numerous epithelia share, only after being reduced to a medullary condition. The result of this process, the chronic catarrhal nephritis, including the desquamation of epithelia and the interstitial new-growth of connective tissue, is shrinkage of the kidneys with a uniformly granular surface.

2. In acute croupous nephritis casts are formed in the tubules, according to the intensity of the inflammation in the narrow tubules, in the convoluted tubules of the second order, and also in the straight tubules. Casts are evidently products of an exudation from the blood-vessels, together with changed epithelia of the tubules. Alfred Meyer holds that the irregular, mainly flat epithelia, as a rule present around the casts, are newly formed after the destruction of the original epithelia had taken place through imbibition with an albuminous exudation. The interstitial connective tissue is considerably infiltrated with inflammatory elements; the capillary blood-vessels, mainly those of the tufts, are dilated, and either choked with blood or with a solid coagulation identical with that of the tube-casts. The result of croupous nephritis, if healing be the termination, are irregular cicatricial depressions on the surface of the kidney, which almost never has decreased in size. The large fatty and waxy kidneys are to be considered as results of secondary changes after primary nephritis.

3. Suppurative nephritis appears either in the shape of disseminated foci of pus, or in the shape of large abscesses within the tissue of the kidney. The formation of pus can be traced both in the interstitial connective tissue and in the epithelia of the tubules. Both kinds of tissues are first reduced into the medullary condition, and in this condition lead through pro-

liferation of living matter to the formation of new medullary or inflammatory elements. Lastly these elements are isolated and bear the name pus-corpuscles. In larger abscesses the pus sometimes becomes inspissated and cheesy, this representing a merely secondary change, independent of tuberculosis.

AN ATLAS IN TWO SEGMENTS.

Dr. BUDDON presented an atlas in two segments, and gave the following account of it:

By the courtesy of Dr. I. C. Foster, of Clarksville, Texas, I am permitted to present a rare specimen from the human skeleton, viz., an atlas in two segments; with it I present a similar normal bone from the adult, so that you may compare the two. It will be found that the two segments would constitute a single bone somewhat larger than the one with which you compare them; the vertebral foramen is certainly larger, measuring laterally and antero-posteriorly one inch and three-eighths, and from the extremity of one transverse process to the other, three inches; the separation or division into lateral halves is through the centre of the anterior and posterior arches; the posterior half arch terminates in a blunt extremity on the left side, and the demi-facet for the odontoid on that side is larger than on the right; on the right side the posterior arch terminates in a point; it is probable that in the recent specimen the extremities of the arches were covered with cartilage and united through the medium of fibrous tissue; but of that nothing is known, for the specimen has no history.

In the April No. of *The Amer. Jour. of Med. Sciences*, 1874, is a woodcut of a precisely similar specimen, obtained from a man about seventy years of age, and described by Dr. W. W. Keen, of Philadelphia. The doctor, a well known teacher of anatomy, says: "It is the only one I have ever seen, and I cannot find, after considerable search, any similar instance recorded."

Opinions vary as to the centres of ossification in the atlas. Gray, Sharpey and Quain give three, viz., one for each of the lateral masses, and one occasionally for the arches. Cruveilhier gives four—one on each side for the anterior and posterior arches. Wilson, one for each arch and each lateral mass. Others as many as six, three on each side.

Beclard says: "Ossification commences in the sides of the atlas near its articulating surfaces earlier than at any other point of the column."

Humphry: "Posterior arches have been found united by bone at five years, occasionally a separate nucleus is developed in the cartilage at the point of their junction. Posterior arches also united at birth by fibrous band, with sometimes a central nucleus, ossified at or before twelve years."

In the Musée Orfila is an adult atlas with the forepart of the arch separate from the sides of the bone, and in Guy's Museum is a specimen of an adult atlas in which union has entirely failed both before and behind, so that the vertebra remains divided into its two primitive lateral portions.

OBSTINATE SINGULTUS CURED BY MURIATE OF PILLOCARPINE.—Dr. Ortille reports a case of persistent singultus, due to cerebral embolism, which proved utterly rebellious to all the usual methods of treatment. As the singultus persisted even during the sleep produced by morphine injections, and the strength of the patient was becoming greatly reduced, a hypodermic injection of half a grain of pilocarpine was at last administered. This produced abundant perspiration and salivation, and the hicough ceased at once.—*Allg. Med. Cent. Zeit.*

NEW YORK ACADEMY OF MEDICINE.
OBSTETRIC SECTION.

Stated Meeting, November 29, 1878.

DR. SALVATORE CARO, CHAIRMAN.

THE VOMITING OF PREGNANCY—TREATMENT BY RECTAL ALIMENTATION.

DR. A. C. POST related the history of a case of severe vomiting in pregnancy, treated by rectal alimentation.

The patient totally abstained from taking food by the mouth for three weeks.

In the month of March last he was called to visit a lady who was the mother of one child about eighteen months old, which she was still nursing. She was considerably depreciated in health. She had not menstruated since the birth of her child. It was advised that the child be weaned, which was accordingly done. She was suffering from nausea and vomiting at the time, and those symptoms were not relieved by the weaning of the child. There was nothing to suggest the idea of pregnancy. An attempt was made to relieve the vomiting by the use of remedies ordinarily employed in such cases, but the treatment failed. At last it was advised that the woman be confined to the recumbent position, that she should abstain entirely from food taken by the mouth, and that entire reliance should be placed upon rectal alimentation. The nutritious enemata consisted of defibrinated beef's blood, beef tea, milk, and pepsine. The quantity given at each injection was about four ounces, and the injections were repeated every three hours. She was kept upon that treatment for nearly two weeks, yet no marked change occurred in her general condition.

A consultation was proposed, and Dr. Alonzo Clark was called. The council agreed that it was best to persevere in the plan of treatment adopted. Neither Dr. Clark nor Dr. Post suspected that the woman was pregnant. At the end of three weeks the nausea and vomiting were very much relieved, and the patient began to retain food upon the stomach. As soon as food taken by the mouth could be retained in sufficient quantity, rectal alimentation was discontinued, but for three weeks there was total abstinence from food taken into the stomach. On the third of October last the woman gave birth to a strong, healthy child of average size. It was Dr. Post's impression that the prostration of the woman was so great in March, she would have died had it not been for the rectal alimentation.

Reference was also made to a case in which the system was sustained nearly to weeks by the exclusive use of nutritious enemata. In that case the disturbance of the stomach was brought on by the too free use of stimulants.

The two cases illustrated the benefit of entire rest when a morbid condition of the stomach, such as prevented it from retaining food, existed.

DR. SELL mentioned the *co. helonias* pill as a very valuable remedy in the treatment of obstinate vomiting of pregnancy. The pill was composed of three ingredients, viburnum, helonin, and caulophyllum.

REMEDIES FOR DILATING THE CERVIX DURING AND PREPARATORY TO LABOR.

DR. SELL related a case as an example of several, in which he had used the concentrated tincture of caulophyllum, or squaw weed, with the happiest results, as a remedy to ward off tedious labor. The

remedy was especially applicable in those cases in which the woman had habitually suffered severely during the first stage of labor. As a preparatory remedy in such cases it should be administered in twenty-drop doses three times a day, for three or four weeks previous to confinement.

DR. MERRILL remarked that he had witnessed similar results from the use of castor oil during labor. He referred to cases in which he had found the os rigid, had ordered a dose of the oil, and, by the time the bowels were freely evacuated, the rigidity had disappeared, and speedy delivery was effected.

He further remarked that he had used castor oil with good effect in cases in which the uterine contractions were weak and the os was considerably dilated. Given in half-teaspoonful doses every ten or fifteen minutes, the oil had produced marked uterine contraction as rapidly as he had ever obtained by the use of ergot.

DR. SELL regarded the oil as a dangerous medicine to be given during the latter months of pregnancy, for if it had the power to excite uterine contraction, it might produce premature delivery.

He also referred to gelsemium as a valuable remedy in cases of rigid os during labor.

DR. MERRILL remarked that he never ordered castor oil, except when he was convinced that it was time for labor, or the process had already commenced. He always charged his patients not to take castor oil during the last months of pregnancy, if remedies were needed to keep the bowels open, because of the liability to excite uterine contraction.

DR. F. V. WHITE remarked that when he was an interne in Bellevue Hospital, it was customary to administer castor oil to the lying-in women on Sundays, and there were marked results following its administration.

He also asked Dr. Sell if he had not obtained as satisfactory results from the use of chloroform in cases of rigid os during labor, as from the use of gelsemium.

DR. SELL replied that he preferred gelsemium to chloroform.

SPONTANEOUS CURE OF VESICO-VAGINAL FISTULA.

DR. W. T. WHITE gave the history of a case as follows: About six weeks ago he saw a case in consultation, with the view to making an operation for vesico-vaginal fistula. The woman had been delivered by instruments about six weeks previous to the time he saw her, and soon after the operation it was found that urine escaped from some false passage. The examination revealed a fistula upon the left side and near to the cervix. There was an opening at least three-fourths of an inch in length, and edges of the rent were slightly everted. As there was a probability that menstruation might occur within two weeks, it was thought advisable to postpone the operation until that process had passed. About ten days subsequently it was noticed that urine had ceased to escape from the vagina, and an examination at the end of three weeks revealed the fact that the vesico-vaginal fistula was completely closed.

YELLOW FEVER DURING PREGNANCY—QUESTION OF TRANSMISSION OF THE DISEASE FROM MOTHER TO CHILD.

DR. CARO related a case as follows:

Mrs. C., 24 years of age, multipara, of German parentage, and a healthy, strong woman. In 1862 she had yellow fever, and recovered. When the epidemic of yellow fever of the present year broke out she was

living in Memphis. Being pregnant, and fearing that disastrous results both to herself and to her child would follow an attack of the disease, she left that city on the 20th of August and came north. The epidemic at that time was at its height. She arrived at New York on the 23d of August, and on the morning of the 25th she was taken with a severe chill. After the chill she began to have labor-pains, which continued for several hours, when a midwife was sent for, who found that labor had commenced. Within twenty-four hours the woman gave birth to an eight-month child, reckoning from the date at which the last menstruation occurred.

After delivery of the placenta, a chill occurred, and after that chill the lochial discharges ceased. Reaction followed, and the fever increased. A physician was sent for, who arrived at the conclusion that the woman had intermittent fever, and prescribed accordingly. After having the first chill, jaundice appeared, and the patient soon after began to vomit a yellowish black substance. When Dr. Caro first saw her in consultation she was suffering from severe headache, was restless, had great hyperaesthesia over the entire body, and the abdomen was tympanitic and painful: the pulse was 110, and the temperature 103° F.; the skin was of a yellow brownish color, and the patient occasionally vomited mouthfuls of very yellow matter; her bowels were confined, and there was retention of urine. Dr. Caro was not certain whether he had to deal with a case of yellow fever or a case of puerperal fever. That puerperal fever was present he felt quite certain, and he was also quite sure that he had to deal with yellow fever. To quiet the patient, and also to act upon the skin, morphine and bicarbonate of soda were given, and nourishment in the form of beef-tea and milk.

On the evening of the same day Dr. Caro again saw the patient and found her sleeping quietly. The skin was moist, and there had been no vomiting since his first visit. The temperature was 101° F., and the pulse 110. No urine had been passed, and there was a tympanitic sound upon percussion over the bladder. The same remedies were continued. On the following morning, at 7 o'clock, the patient was again restless, and the dose of morphine was increased from one-eighth to one-fourth of a grain every two hours. The temperature was 101° F., and the pulse 110. No urine had been passed, and there had not been any movement from the bowels. With the double view of satisfying both himself and the Board of Health, Dr. Caro asked that Dr. Janeway should see the patient in consultation. A consultation was held, and the conclusion reached that puerperal fever was the predominant disease, but that yellow fever was also present.

Although the woman was in a precarious condition, it was insisted by the Health Board that she should be sent to Quarantine. She was removed, and died at Quarantine on the third of September. The special point of interest, from a scientific view, was that the child was born healthy and had remained free from the disease. If the mother had yellow fever, the supposition would be that the child should have died from the same disease.

Dr. Caro had no doubt but that the yellow fever, associated with the three days' trip from Memphis, brought on the premature delivery.

The fact that the child survived was evidence to sustain the doctor in the belief that yellow fever was not transmitted from mother to child, as was supposed to be the case with scarlet fever and small-pox.

Again, if a child, in the uterus of a woman suffer-

ing from yellow fever, did not receive the poison of that disease, how could a child be narcotized by a hypodermic injection of morphine administered to the mother?

Dr. W. T. WHITE asked if it was the prevailing opinion that a child delivered while the mother was suffering from yellow fever, must necessarily have the same disease?

Dr. CARO replied, that he thought it was.

Dr. WHITE referred to a case in which a pregnant woman had well-marked yellow fever from which she recovered, and at full term, about two months later, gave birth to a living healthy child.

The Section then adjourned.

Correspondence.

THE LEGALITY OF MEETINGS OF THE STATE SOCIETY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In reply to the article on page 37 of the current volume of the RECORD, with reference to the legality of some of the late meetings of the Medical Society of the State of New York, it may be stated that good legal authority, after full presentation of the facts, decided, and so advised the President of the Society elected in June, 1877, that the meeting then held was a perfectly legal annual meeting, and consequently its election of officers valid. Its action, however, in changing the time of holding the annual meeting to the third Tuesday in January was not in compliance with the statute, and therefore the change was illegal and void. At the meeting held January 15, 16, and 17, 1878, it was decided by the members present that that meeting, though not the annual meeting for 1878, was to all intents and purposes an adjourned session of the annual meeting of 1877, and hence a meeting at which a notice of intention to change the time of the annual meeting could properly be given. The change was actually made at the annual meeting held June 18, 1878, and the time for the annual meeting fixed for the first Tuesday in February of each year.

The Register of the Society gives evidence that the annual meeting for 1876 was duly held on Tuesday, February 1, 1876. There were twenty-three in attendance—five delegates and eighteen permanent members—or more than a legal quorum. They had, therefore, full authority to adjourn this annual meeting to June, 1876.

By reference to page 62, Transactions 1869, it will be seen that the act passed April 23, 1823, though entitled an "Act to enable the County Medical Societies in this State to alter the time of holding their Annual Meetings," confers that ability on *any society* incorporated under the act entitled "An Act to incorporate medical societies," etc. By reference to that act, as published in the Transactions for 1869, page 59, section 3, it appears that the Medical Society of the State of New York was virtually re-incorporated under that act, and therefore became enabled by the act of 1823, to change the time of holding its annual meetings. The act of February 1, 1876, appears to have been unnecessary.

Yours respectfully,

WM. MANLIUS SMITH, *Secretary.*

7 MYERS' BLOCK, SYRACUSE, N. Y., Jan. 13, 1879.

DETERMINATION OF SEX IN UTERO.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The following *facts* (for which I can vouch) may be of interest to your readers.

A and B were married 8th May, 1861. Cessation of menses, 5th May, 1861; intercourse on night of marriage, resulting in a *son* still-born, 13th January, 1862.

Menses ceased 29th July, 1862; coition 31st July, 1862; *son* born 15th April, 1863. No return of menses after birth of this child, but a *daughter* was born 30th October, 1864.

Menses ceased 15th May, 1866; coitus, 18th May; *daughter* born 16th February, 1867.

Menses ceased October 13, 1868; coitus, 15th October; *son* born 10th July, 1869.

Menses ceased 20th March, 1870; coitus, 23d March; *daughter* born 27th December, 1870.

Menses ceased 24th June, 1872. Husband returned after a long absence, 10th July, 1872. Menstruated 18th July; *son* born 10th April, 1873, nine months exactly from date of husband's return.

Menses ceased 20th December, 1875; coitus, 22d December; *son* born 19th September, 1876.

Menses ceased 20th January, 1877; coitus, 23d January; *son* born 27th October, 1877.

In this record of six sons and three daughters, *experience* proves that *either* sex may result from coitus immediately subsequent to menstruation.

MENACRATES.

STATE SOCIETY AND NOMINATING COMMITTEE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your editorial in the last number of the RECORD, January 18th, p. 63, on "The State Medical Society," you are in error in saying that I recommended that the by-law in regard to the mode of forming the Nominating Committee be changed to the present form. The credit for that change is due to Dr. James V. Kendall, of Baldwinsville, Onondaga County. He had proposed and advocated the change at previous annual meetings, and by thus setting many members to thinking of it, it was found that at the meeting of 1877 the Society was prepared to adopt his proposition as an improvement on the then existing plan.

In the President's address to which you refer there is a recommendation to correct the usage of permanent members only being eligible to offices and committees of the Society. And upon this, and most of the other recommendations the Committee on the Address did report adversely.

Very respectfully yours,

E. R. SQUIBB.

BROOKLYN, Jan, 20, 1879.

THE YELLOW FEVER FUND.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—A check for \$58 has been received from Dr. Cibell, of Richmond, Virginia. The \$2,000 subscribed by the New York Chamber of Commerce has not yet been called for, nor the \$250 from the Secretary of State; nor will they be, until the list of the sufferers is complete. One thousand dollars has been forwarded to Memphis, and it is hoped that more can soon be sent. The arrangements with Grenada, Mississippi, are also most perfected. No replies have been received from

Vicksburg, Hollysprings, and various other places, which have been written to. Communications have been received from Dr. C. B. White, of New Orleans, and N. E. Ravena, of Charleston, S. C., both recommending a special family as having strong claims upon the profession. The committee again respectfully and earnestly urges its request for all obtainable information.

J. C. PETERS, *Chairman*.

Obituary.

JOHN BARCLAY BIDDLE, M.D.

DR. JOHN BARCLAY BIDDLE, professor of materia medica in the Jefferson Medical College, dean of the college faculty, and President of the Board of Inspectors of the County Prison, died at seven o'clock on Sunday evening last, at his late residence, 331 South Seventeenth Street, Philadelphia. Dr. Biddle had been an invalid for the last four or five years, and took frequent trips to Europe to improve his health. Two weeks ago he was attacked with a severe cold, causing congestion of the lungs and pleurisy, which conditions finally assumed a typhoid type and brought on death.

Dr. Biddle was the eldest of the sons of Colonel Clement C. Biddle, a Philadelphian by birth, born January 3, 1815, who in early life was an officer in the military and naval service of the United States, and who, later, was for a long period President of the Philadelphia Savings Fund. Always inclined towards the medical profession, it was not long after attending schools in this city and graduating from St. Mary's College at Baltimore that he entered the medical department of the Pennsylvania University, under the special instruction of Dr. Nathan Chapman. Upon the completion of his studies there he visited Paris, and placing himself under the instruction of the best teachers, devoted considerable time to lectures and hospital work in that city. Returning to Philadelphia, with Dr. Meredith Clymer he started the *Medical Examiner* about the year 1842. This journal was a weekly periodical devoted to medicine, and achieved success. Dr. Biddle, after a few years as editor, entered upon private practice. In 1844, in connection with Professor Joseph Leidy, Drs. Paul B. Goddard, David H. Tucker, and Dr. Joynes, he founded the Franklin Medical College, which stood for years in Philadelphia on Locust Street near Twelfth. All the supporters of the college gradually withdrew from it to other pursuits, and the college died out; but during its short career it graduated many students who are now distinguished physicians. Upon the death of Dr. T. C. Mitchell, which occurred in 1865, Dr. Biddle, in the fall of that year, was elected to the vacant professorship of materia medica in Jefferson College. Placed in this position he turned all attention towards the preparation of a treatise on materia medica for students, which was accepted by the faculty of Jefferson College, and reached an eighth edition. Soon after taking this chair Dr. Biddle was made dean of the college faculty, and continued both dean and professor uninterruptedly until death.

A dozen years ago Dr. Biddle was appointed Inspector of the County Prison, and a little later the board made him their president. He was attending physician of the Deaf and Dumb Asylum and of Girard College. He frequently contributed to the medi-

ed press. A family of six children and a wife survive him. Of his two sons, Clement, after graduating from the Jefferson Medical College, passed an examination qualifying himself as surgeon in the navy. Recently he sailed for the Mediterranean in an official capacity. William is a navy lieutenant.

New Instruments.

A DOUBLE FORCEPS.

By C. J. CLEBORNE, M.D.,

MEDICAL INSPECTOR, U. S. NAVY.

The little instrument figured in the accompanying illustration combines in a compact form an artery, bulldog and tissue forceps, and two needle-holders.

Like other forceps, they are designed to take the place of the fingers where objects are too small to be grasped by them, or when they cannot be used to advantage. The fenestrated jaws, which I have called "tissue forceps," will be found useful for holding the skin for the passage of needles in making sutures in hare-lip and other operations. It will save pricking the fingers, will hold the tissues firmly, and may be used for temporarily arresting hemorrhage. Both ends of the instrument are deeply grooved to hold needles or pins at any angle, while the inner borders of the points are cut transversely, and are double-toothed, to retain securely an artery or other small object. The blades are held together by the Liston spring, and their middle sections and sides are file-cut so as to prevent the fingers slipping. It is handsomely manufactured by the Messrs. Tiemann, at a very moderate cost, and, with or without my tenaculum-needle, will be found a useful addition to the pocket-case.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 12th to January 18th, 1879.

KOERPER, E. A., Capt. and Assistant Surgeon.—Leave of absence granted by S. O. 110, December 3, 1878, from Headquarters Department of the Platte, extended three months. S. O. 12, A. G. O., January 15, 1878.

BARNETT, R., First Lieutenant and Assistant Surgeon.—Assigned to duty at these headquarters from 2d inst. S. O. 3, Department of the Platte, January 6, 1879.

GRAY, C. C., Major and Surgeon.—Retired from active service in conformity with section 1252 Revised Statutes. S. O. 8, A. G. O., January 10, 1879.

DR. S. H. SHANNON, a graduate of the class of 1836 in Jefferson Medical College, died at Schuylkill Haven, Pa., on January 17th, after a lingering illness. He was born at Shannonville, Pa., in 1814. The deceased had a varied and extensive practice of forty years, which gave him a position as a skilful practitioner. He was one of the largest property-holders in the county.

MEDICAL SOCIETY OF THE STATE OF NEW YORK. — The seventy-third annual meeting of the Medical Society of the State of New York will begin its Sessions in the city of Albany, on Tuesday morning, February 4th, at 9 o'clock.

The following-named gentlemen have notified the President or Secretary of their intention to present papers for the consideration of the Society: E. R. Hun, "Cavernous Angioma of Tongue;" W. C. Wey, "Twenty-seven Cases of Pleural Effusion, requiring Aspiration;" H. G. Piffard, "Further Contributions to the Treatment of Lupus;" J. R. Leaming, "Phthisis Pulmonali, Classification and Practical Consideration;" Lewis A. Sayre, "The Traumatic Origin of Subfascial, Deep-seated, or Cold Abscesses;" J. S. Prout, "The Anatomical Relations of the Middle Ear;" E. M. Moore, title unannounced; J. C. Dalton, (1) "Scientific Ghosts," (2) "Sections of the Brain;" A. Jacobi, title unannounced; Fordyce Barker, "Some of the more Recent Methods of Treatment of Albuminuria and Uremic Convulsions;" E. R. Squibb, (1) "Note on the Estimation of Urea," (2) "Revision of the U. S. Pharmacopœia in 1880," (3) "Draft of a Proposed Law to Prevent the Adulteration of Food and Medicine, and to Establish a State Board of Health;" Chas. G. Bacon, "Incubation Period of Scarlet Fever;" C. R. Agnew, "Cataract;" W. T. Lusk, "The Treatment of Hemorrhage in Abortion;" H. D. Noyes, "Address on Ophthalmology;" A. Van Derveer, "Uterine Fibroids, a New Treatment;" Norman L. Snow, "Practical Facts Verified by the Treatment of Twenty-five Cases of Fracture of the Femur;" R. F. Weir, (1) "Supra Condylloid Amputations of Thigh," (2) "Carbolized Jute as a Wound Dressing;" L. D. Bulkley, "The Use of Water in the Treatment of Diseases of the Skin;" W. S. Ely, title unannounced; Alfred C. Post, (1) "Description of a Rhino-Plastic Operation," (2) "Some of the Therapeutic Uses of the Actual Caustery;" Stephen Smith, "Carbolized Catgut Ligatures in the Treatment of Aneurism;" F. R. Sturgis, "On the Abuses of Medical Charities from a Medical Point of View;" Wm. A. Hammond, "Non-Asylum Treatment for the Insane;" D. Webster, "Glaucoma;" Beverley Robinson, "Ulcerative Phthisical Laryngitis and the Value of Tracheotomy in its Treatment;" T. E. Satterthwaite, "Personal Observations in One Hundred Cases of Cancer;" H. T. Hanks, "The Early Diagnosis of Occipito-posterior Positions;" A. L. Loomis, "The Adirondack Region as a Therapeutic Agent in the Treatment of Pulmonary Phthisis;" C. S. Hull, "Pilocarpine;" A. L. Ranney, "Causes of Death during Surgical Operations;" L. Johnson, "The Action of Baptisia Tinctoria in Typhoid Fever;" A. McL.

Hamilton, title unannounced; Alex. Hutelins, "Report on By-Laws;" J. C. Hutchison, title unannounced; J. P. Cruveling, "Laparotomy for Intestinal Obstruction;" Walter B. Chase, "A Case of Dislocation of the Acromial Extremity of the Clavicle downward;" E. G. Loring, "Effect of Optical Condition of the Eye on the Development of Character;" W. H. Thomson, "The Relation of Vascular to Nervous Diseases." The President will deliver an address on "The Relations of the Medical Profession to the State."

Gentlemen who propose to present papers will confer a favor on the officers of the Society by communicating with the President or Secretary at once.

DEATH OF PROF. LONDON R. LONGWORTH, M.D., OF CINCINNATI, OHIO.—It is with deep regret that we hear of the death of Prof. Longworth, which occurred January 14th, as the result of an attack of pneumonia. He for some time past occupied the chair of Descriptive Anatomy and Clinical Surgery in the Medical College of Ohio. Endowed with great natural talent, and being a gentleman of high education, and an industrious and efficient worker withal, he gave great promise of a brilliant future. Although comparatively young in years, he made some valuable contributions to histology, a branch of science which he cultivated with great assiduity.

THE CAROLINA TWINS AT A PHILADELPHIA CLINIC.—The much-advertised "Carolina Twins" were subjected to a scientific examination at Prof. Wm. H. Pancoast's clinic at Jefferson Medical College Hospital, on Saturday last. Before their entrance Dr. Pancoast read his memoranda of the examination of the twins, which he made about eight years ago. He considered the case a much more remarkable one than that of the Siamese Twins, who were two distinct persons, joined by a ligature only, whereas the Carolina colored women had but one backbone in common below the shoulder-blade. Above this point the spinal column branched like the arms of the letter Y. At their birth they were directly back to back, but as they were learning to walk they naturally twisted themselves considerably in order to facilitate locomotion. This change from their original relative positions it was possible to effect without injury or pain to either of them, owing to the softness and pliability of the bones in early youth. There was on record but one case that might be supposed to have been a parallel to that of the Carolina twins. This was that of the famous Hungarian sisters, who were born in 1701, and died in their twenty-second year. Their bond of union, though never scientifically determined, seemed to have been the same as that of the Carolina twins. They differed from the Carolina twins, however, in not possessing the same general characteristics.

Dr. Pancoast showed that if either of the twins were touched upon, or at any point below where the body was common to both, each of them would feel it, but that if he were to touch one of them above the point where the spinal column branched, the communication would reach only the brain of the one touched. He demonstrated, however, that the line was moving higher which divided their common from their separate and distinct nervous sensitiveness. Eight years ago a touch half an inch higher than the common part of the spine could be felt by both; but any farther up the sensitiveness was not shared by the person untouched. Now, however, it was proved by experiment that the common sensitiveness to a touch of the same character existed in either body at least two inches above the angle formed by the Y branches. Dr. Pancoast believes that the twins would die together.

EFFICIENT QUARANTINE—The following extract from the annual report of Health Officer Vanderpoel to the Quarantine Commissioners is interesting in its bearing upon the question of intelligent quarantine as connected with yellow fever:

"A large number of vessels from ports known to be infected arrived during the past season. Of these an unusual number had sickness and deaths from yellow fever, either while lying in port, on their passage hither, or after arrival.

Forty-five cases of sickness were in the lower bay and at the hospital; of these thirty were yellow fever, and fourteen deaths. Five of these were from sick taken from vessels; three died on vessels arriving, and six from cases received from New York, Jersey city and Brooklyn.

From the ninth of June until the last of September there was not an interval of three days without cases of yellow fever being in the bay. During all that period not the slightest excitement or alarm was manifested by this immense community at its near proximity; nor did a vessel, whether infected or having sickness on board, lose her sailing day from this port.

THE PROPHYLAXIS OF SCARLET FEVER.—A. Hurd, of Finlay, Ohio, in the report of a severe case of scarlet fever occurring in a family of children, writes:

"There were four other children (three younger than the patient, and one older) in the family.

"Must they also have the fever? Can it be prevented? With this view I order the window-curtains to be taken down; all unnecessary articles of clothing to be removed; use carbolic acid freely; ventilate rooms well, and, thinking it will do no harm if no good, put the other children on fld. ext. belladonna and hyposulphite of soda, in doses sufficient to produce redness of the skin and well-marked enlargement of the pupils. Continue it through the whole duration of the sickness of the boy and girl, and to my great gratification all four of the children escaped and remained free from the disease, and do till this date. Was it a happy and wonderful coincidence, Was it good ventilation, careful hygiene, and cleanliness, or did belladonna and the hyposulphite of soda, etc., act as a prophylactic?"

A NEW PHILADELPHIA MEDICAL JOURNAL.—We take pleasure in recording the announcement of the early appearance of another medical journal. The new-comer is the "Medical Bulletin," a sixteen-page octavo, to be edited and published by the Jefferson Medical Association of Philadelphia, and distributed gratuitously. The contents are to consist principally of original matter, having strict reference to the regular practice of medicine and surgery. A particular feature is to be a student's department, in which topics of special difficulty to beginners in medical science will be discussed in a practical way. The journal will begin its existence as a quarterly.

GINTRAC.—Henri, Dean of the Medical Faculty of Bordeaux, and Professor of Clinical Medicine, died in Bordeaux on December 2d, of organic disease of the heart. He was 58 years of age. It is less than a year since we had to record the death of his father, also a prominent teacher of medicine.

A CORRESPONDENT in *The Lancet* admonishes his readers to order "Merek's Extractive Hyoseyamine" in order to obtain uniform results from the remedy. The dose is that of atropia (which it resembles in physiological action) gr. $\frac{1}{50}$ to $\frac{1}{60}$.

Original Communications.

CONTRIBUTION TO THE TREATMENT OF NEURALGIAS.

By WM. B. NEFTEL, M.D.,

NEW YORK.

In looking over my notes on cases of neuralgia, treated by me in the last eleven years, I was surprised to find some features which repeat themselves with great uniformity in almost every instance. They are, therefore, of general interest as characteristic of this class of nervous affections.

The cases of neuralgia which came under my observation were, without exception, of very long standing, having lasted from five to fifteen years and more, and having resisted all methods of treatment. Such cases can serve as a practical test of the efficacy of the methods of treatment employed. While many other chronic affections may, with an indifferent treatment and under favorable circumstances, assume a milder form, or even tend toward recovery, these inveterate neuralgias never improve spontaneously; but, if left to themselves, or not under a proper treatment, invariably remain incurable. Such patients generally become convinced of the incurability of their affection, and, after having tried in vain almost every remedy, they are obliged to resort to certain palliatives in order to mitigate the severity of the attacks, until some intercurrent disease puts an end to their suffering. Sometimes the acute disease does not terminate fatally, and may produce a favorable change in the general health, and modify or even cure the neuralgia. It is remarkable that, from a large number of narcotics which are used as palliatives, only a few afford relief in each individual case, and are therefore permanently employed. Prominent among all is morphia, which is generally resorted to by the physician, whether a member of the regular profession, a homœopath, or belonging to any other school—even the doses being precisely the same, *i. e.*, the quantity necessary to afford relief. The consequence is, that the majority of sufferers from severe neuralgia acquire also the morphia habit. Much depends, however, upon the frequency of the paroxysms of pain. Where they appear at long intervals, allowing the patient time to partially recover, this habit may be avoided; but where the patients suffer almost incessantly, or where the paroxysms repeat themselves at irregular short intervals, the patients nearly always acquire the morphia habit, the latter often being ignored both by the patient and the physician. I select, as an illustration, one of many similar cases which have come under my care at that stage of the disease.

Miss F., *æt.* 17, suffered from severe headaches since her tenth year. Her mother and grandmother have been always subject to attacks of sick headache, and it was presumed she had the same affection, aggravated by the inherited disposition. Her father is habitually intemperate. The attacks appeared first at considerable intervals, then became more frequent, and during the last three years the patient was scarcely ever free from headaches, which often increased to an unbearable severity. In her fourteenth year menstruation appeared with a great deal of pain, and since that time she has always suffered from dysmenorrhœa accompanied with intense headache. She was treated with bromide of potassium, guarana,

cannabis indica, nitrite of amyl, etc., but morphia alone afforded relief, and was, therefore, always resorted to, at first per os, and afterwards hypodermically. During the last three years she was kept more or less under the influence of morphia, as it became absolutely necessary, on her awaking with intense headache, to make every morning a hypodermic injection of $\frac{1}{2}$ or $\frac{1}{4}$ gr. of morphia, after which only could she get up and take her breakfast. Whenever an attempt was made to omit the hypodermic injection she would be unable to leave her bed or take food, and the headache would become unbearable, last in an aggravated form during several days, a week or more, and resist even the increased doses of morphia. For the last four months she had regularly three hypodermic injections per day, and during the severe attacks of headache the doses of morphia had to be increased and the injections repeated several times during day and night. The patient, whom I examined for the first time Aug. 28, 1878, was brought to me for treatment by the family physician, Dr. Gibson. She was below medium size, very pale and delicate, flushed readily, felt weak, had little or no appetite, and was habitually constive. The pulse was small and accelerated, the skin dry, the tongue pale and coated. No fever. She had an incessant cough in consequence of a cold contracted about ten days before. Of late she had been catching colds very easily, which always called forth a cough that lasted a long time and was hard to get rid of. The principal seat of the neuralgic pain was the right supraorbital nerve. Except a slight bronchial catarrh, no organic affection could be detected. Her menstrual period passed a day or two before. It lasted, as usual, about a week, and was accompanied with intense dysmenorrhœa, making it necessary to keep her under the full influence of morphia.*

Evidently, in this case, we had two indications, *viz.*: to treat the headaches and dysmenorrhœa, and to remove the morphia habit.

As a preliminary step the bronchial catarrh was treated by promoting the action of the skin. The patient was ordered warm drinks, mostly hot lemonade, which she found particularly pleasant, having a craving for lemons, the use of which was, however, prohibited before, but which I have always found beneficial in such cases. Besides a nourishing diet and out-door exercise, hydrochloric acid was prescribed after meals, and as soon as the bronchial catarrh disappeared and the digestion improved, iron was given. Every time I attempted to omit the dose of morphia, or even diminish it, the attacks of headache became so violent (with loss of appetite and sleep, and a complete inability to rise) that they had to be controlled by more frequent and increased doses of hypodermic injections. But, under the galvanic treatment and a tonic régime, her health grew better and the headaches became more manageable. Sept. 28th, menstruation returned with dysmenorrhœa and headache. Pulse small and contracted, face pale, expressing great agony. Like on all former occasions, it seemed indispensable to keep her under the complete influence of morphia; but I decided to abolish abruptly the morphia habit, and in order to do so substituted temporarily for this alkaloid another palliative—Merck's hyoscyamine—in small doses. Its effect was prompt, but appeared somewhat alarming, as the face became red, the eyes congested and protruding, the pulse full, the speech incoherent, though at the same time the pains entirely subsided. After a few hours this condition gradually wore off. Then she became troubled with optic hallucinations, all the

objects appearing distorted. She fancied herself surrounded by different animals, and dreaded their sight. She could not keep anything on the stomach, and incessantly asked for morphia. In the evening her condition looked quite alarming; terror-stricken with the hallucinations, without food, and with a filiform pulse, a collapse seemed inevitable, and I almost feared I should have to yield to her continual request and administer a small dose of morphia. However, under the influence of stimulants, her pulse grew stronger, she took some beef-tea, and fell asleep. Under reduced doses of hyoseyamine, for which were afterwards substituted larger doses of quinine, she gradually improved. The dysmenorrhœal pains and headache ceased on the third day, and her appetite improved. The next week I resumed the use of iron and the galvanic treatment, under which she rapidly recovered, had no headaches, could walk a great deal, and sleep without narcotics. Her next period came, for the first time in her life, without pain. She could go out daily during the menstruation, and felt quite well. She remained one month longer under my observation, and left New York for her home in perfect health.

In treating such inveterate cases of neuralgia we have to bear in mind the probable complication with the morphia habit. Generally the opinion prevails that with the cure of the headache or other suffering the necessity for administering morphia would cease, which, however, always proves incorrect; and in the case above related, the patient confessed later, that, even with the removal of the headache and dysmenorrhœa, she would have been unable to live without morphia, had it been left to her. In such cases, after ameliorating the general health, and modifying to a certain degree the severity of the neuralgic attacks, I discontinue abruptly the administration of morphia, and temporarily substitute for it some other palliative. In the above related case, the small, contracted pulse, the pallor of the skin, and the cold extremities, suggested the use of a remedy producing a contrary effect, and as nitrite of amyl had already proved unsuccessful, I selected the hyoseyamine; and should this have failed, I intended to try pylocarpine, which I have found useful under similar circumstances.

As already mentioned, the morphia habit most frequently accompanies inveterate neuralgias. I have had, however, several cases of neuralgia with ether habit, and some, more recently, with a habit of chloral.

Mrs. B. was placed under my treatment by her husband, a distinguished physician, in January, 1873. She was about forty-three years old, and mother of several healthy children. She had suffered for many years from severe headaches, which would not be controlled by any other remedy but inhalation of ether, which, therefore, had to be resorted to in every attack to alleviate the pain. Small quantities were at first sufficient, but soon the attacks recurred more frequently, lasted longer, and made it necessary to gradually increase the doses of ether until it became large enough to produce complete anesthesia. I was called to see the patient during one of her attacks, and found her in a complete coma, with the face flushed. As soon as consciousness began to return she called for more ether, and grasped at the paper cone, pressing it to her mouth and nose until complete coma ensued. This was continually repeated during twenty-four hours, and even during several days. While the attack lasted the patient ate scarcely anything, and it generally took some time before she returned to her normal

state. Under the galvanic treatment the attacks became less frequent and more manageable; but I explained to her husband that, unless the ether habit were given up, a radical cure would be impossible. Last year she had typhoid fever of a severe type, her life being in danger for several weeks. She, however, entirely recovered, and is now in excellent health, and perfectly free from neuralgia. No doubt the prolonged acute illness wrought a favorable change and was instrumental in her losing the ether habit.

Very frequently, persons suffering from severe neuralgias acquire the habit of alcoholic stimulants, which presents itself in two different forms. In cases where the attacks appear at long intervals, the patients intoxicate themselves to unconsciousness at the beginning of the attack, and for several days continue in that condition by taking more stimulants each time they arouse from it, and during the attack scarcely accept any food. They gradually recover, and remain healthy, perfectly abstaining from drink, until the next attack. This form may continue for years, until death is caused by pneumonia, cirrhosis of the liver, fatty degeneration of the heart, Bright's disease, or, still oftener, cerebral apoplexy induced by the degenerated cerebral blood-vessels. However, if the neuralgic attacks do not occur frequently, such patients may recuperate almost entirely during the intervals; but often, even if the neuralgic attacks entirely disappear in course of time, the habit of periodical intoxication remains and brings the ultimate fatal result.

As far as my experience goes, periodical inebriety is generally developed by two morbid conditions, viz., periodical attacks of severe neuralgia, and periodical melancholia, and although these exciting causes may ultimately cease, the inebriety remains permanently. In periodical melancholia there is every reason to admit an anemic condition of the brain, at least of certain regions, caused by a spasmodic contraction of the blood-vessels.* The effect of alcohol counteracts it by producing a paralytic dilatation of the blood-vessels, thus temporarily relieving the morbid state induced by the vaso-motor spasm. Very probably similar conditions exist during the neuralgic attack.

The other form of alcoholic habit consists in the chronic poisoning of the system by the frequent or constant use of small doses. Its effect is often more deleterious than even in the first form; it undermines the constitution, constantly increases the severity of the attacks, and invariably leads to the incurability of the neuralgia.

Mrs. N., wife of a clergyman, thirty-eight years old, and formerly healthy, has been suffering for years with violent headaches. These attacks, which first appeared occasionally, soon became more frequent and more severe, and necessitated the use of large doses of morphia to produce complete narcotism. The pain was deeply seated in the back of the head and also behind the eyes, and often so intense that, to deaden it, she would strike her head against the wall. The after-effects of the morphia were exceedingly unpleasant, causing for several weeks a complete loss of appetite, of sleep, and strength, when a new attack would come on and leave the patient utterly prostrated. During the last years she scarcely had any intervals between the attacks, and ate almost nothing, and it was therefore often necessary to give her small doses of alcoholic stimulants to prevent fainting and collapse, which several times lasted so long

* Nefel: Ueber periodische Melancholie, *Centralbl. f. med. Wiss.* 1875, No. 22; *Med. Rec.*, Aug. 14, 1875.

as to threaten her life. I saw her for the first time January 31, 1872. She was greatly emaciated, the skin pale with a yellowish tint, especially the conjunctiva; the pulse small, with irregular intermissions; the respiration slow; the abdomen sunken in; the liver of very small size; the spleen enlarged. She was subject to looseness of the bowels and sore throat. Her hearing was much impaired; she could not hear a whisper or the ticking of a watch, and besides, had tinnitus aurium—singing and roaring. The examination with the galvanic current showed hyperæsthesia of the auditory nerve, with reversion of formula and paradox reaction of the unarmed ear. Under the influence of the cathode the noises ceased.

This patient was supported by small doses of sherry, brandy, or whiskey, as even the idea of food was sickening to her, and she had to make great efforts to swallow the smallest amount of anything. Being of a high moral character, she took the stimulants with repugnancy, to sustain life, at the recommendation of her physicians, in quantities of half a wineglass or more, and, though very often, yet with not the slightest intoxicating effect.

Neither the patient, nor her husband, nor even the attending physicians suspected that these small doses of alcohol could be injurious or produce the constitutional effects of chronic alcoholism. But though the single doses were small and insufficient to cause intoxication, yet the quantity taken in twenty-four hours was very considerable, and the amount administered during the years of suffering was certainly enormous. In this case the alcohol was still more injurious, as it was taken with little food, and very often on an empty stomach. There was every reason to assume here a considerable degree of cirrhosis of the liver, of fatty degeneration of the heart, and an atrophic condition of the nervous centres.

The described cases selected from a large number of similar ones, show that severe neuralgic affections often become complicated with a morbid habit of morphia, ether, chloral, alcohol, etc. Accordingly, great discretion is required in prescribing narcotics as palliatives in chronic neuralgias, and in case of necessity frequent changes have to be made, never allowing the same narcotic to be taken for any length of time. Even if the pain can be entirely controlled by some narcotics, constant efforts must be made to discontinue entirely their use by curing the neuralgia with some other means. This is especially to be borne in mind in cases of alcoholic habit, and I find it absolutely necessary to insist that such patients abandon altogether the use of alcoholic stimulants, which always leads to a fatal result.

As in all other branches of practical medicine, the success in the treatment of neuralgias greatly depends upon the exactness of the diagnosis. By the latter, however, is not meant only the finding of a technical name, or even the determining of the affected nerves or nerve-centres, but also the detecting of all other constitutional and local peculiarities in each individual case. For instance, in severe neuralgic affections it is easy to diagnose a general anæmic condition, which, however, may be the result of various causes, and not always indicate the use of iron, quinine, etc. Where anæmia depends upon some affection of the digestive organs (chronic gastric catarrh, etc.), no amount of iron will do any good as long as the patient is unable to digest the necessary quantity of food. Again, where anæmia is caused by the derangement of the organs which prepare the blood (not the least important among which are the bones—medulla ossium), even a large amount of well-digested food can-

not correct the abnormal condition of the blood; and every practitioner has met with persons who have a good appetite and digestion, but nevertheless remain thin and bloodless.

The success of the cure therefore depends entirely on the exact diagnosis of the nature of the affection and its etiology, of which the following case, recently under my observation, affords an excellent illustration.

Mrs. S., a lady of about 46 years, consulted me Oct. 1, 1878. She is of a strong constitution, very well built, but for years has been suffering from abdominal pains, which at times become quite unbearable. For the last four years she has been unable to walk, partly from general debility, and also at the advice of her physicians, in order to avoid increasing the pain or calling forth an attack. Last year she was treated during five months by a distinguished physician and clinician of this city for an assumed ulcer of the bowels, but no improvement followed. Then the pains were ascribed to a uterine trouble, but a prolonged local treatment gave no relief. A careful examination of the patient, made by me, revealed no affection of internal organs; the urine, however, showed traces of lead, and she then gave me for chemical analysis a cosmetic she was in the habit of using. I found that it contained over 90 grains of lead in the fluid ounce. It was evident that she had been suffering from lead-colic, and consequently all the methods of treatment employed previous to my diagnosis were useless, to say the least.

The galvanic current is the most efficient agent in the treatment of neuralgias; but here more than anywhere else, success depends entirely upon the method employed; an improper method may often prove altogether useless or even injurious, as for instance in the following case:

Mrs. D., 33 years old, suffered for more than fifteen years from most excruciating pains (like tooth-ache) in the left thumb. This pain interfered with her sleep and occupations, and rendered her emaciated, anæmic, and almost cachectic-looking. She was treated by most eminent physicians, but unsuccessfully, and was at last advised to have the (in appearance healthy) thumb amputated. Dr. Brown-Séquard, however, dissuaded her from having it done, as he considered it very doubtful if the operation would effect a cure. At the advice of Dr. Mussey, of Cincinnati, the patient consulted me May 15, 1873, and frankly said she expected no benefit from the galvanic treatment, having tried it three times before at the hands of competent specialists, and having always found the neuralgic pain aggravated by electricity. Notwithstanding the unfavorable prognosis, she was entirely relieved by me from pain in the course of one month's treatment with the galvanic current, left New York June 18th, and has never had a relapse.

The beneficial effect of the galvanic current in neuralgias is especially apparent in sciatica; even the intensest and most inveterate forms often yielding in a short time to the galvanic treatment.

The illustrations would be too numerous to be given in this paper, but I may add that the polar method, and the skilful use of the rheostat as an accessory current, will often be found of great value in the treatment of intractable neuralgias, especially of sciatica.

OPIUM HABIT AND AMYL NITRITE.—Dr. Leyman (*Boston Medical and Surgical Journal*) has successfully used *amyl nitrite* in insomnia consequent upon suddenly discontinuing the opium habit. Two or three whiffs, the *flushing of the face being the criterion*, were usually sufficient, being followed by refreshing sleep.

FOUR CASES OF EXSECTION OF THE HIP-JOINT,

WITH REMARKS,

By CHARLES T. POORE, M.D.,

SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO CHARITY HOSPITAL, NEW YORK.

IN the May number of the *New York Medical Journal* for 1877, I published seven cases of exsection of the hip-joint. The following is a continuation of the series:

CASE VIII.—Florence M., aged 5 years, was admitted into St. Mary's Free Hospital for Children, June 3, 1876, suffering from hip-joint disease in the second stage. But little account of her previous or family history could be obtained. Patient was put to bed, and absolute rest given to the joint.

In September an abscess was discovered on the anterior aspect of the thigh, just below Poupert's ligament; this was opened, and considerable pus, containing oil-globules, evacuated. The joint was carefully examined while the patient was under ether, but no roughness could be detected. The abscess continued to discharge, and in February a small piece of bone came away. Crepitus could now be detected. Appetite poor. Temperature high in the morning (102°), coming down to 99° in the evening. Discharge free and healthy. Some vomiting.

Feb. 12.—Joint excised. Section was made below trochanter major. The compact tissue at this point was of normal thickness and hardness. The trochanter major was almost detached from the shaft. About one-half of the head had disappeared, and there were loose pieces of bone in joint. Acetabulum perforated. The wound was closed, except opposite the acetabulum, into which a drainage tube was inserted, and the limb bandaged, so as to bring the parts intimately together, a space being left for the drainage-tube.

Feb. 17.—Since operation the temperature has been normal. The wound almost closed.

Feb. 24.—For the past two days patient has been in a semi-unconscious state. Can be roused. Pupils dilated and sluggish. Abdomen retracted. No albumen or casts in urine.

Feb. 29.—Patient gradually failed, and to-day died.

Post-mortem: Body much emaciated. On opening the skull the meninges were found congested. The sulci were filled with a semi-opaque gelatinous material which glued them together. At the base this material was more abundant. Small granular bodies were found along the course of the vessels, and the choroid plexus was studded with them.

The parts about the hip-joint look well. There was a small abscess cavity between the femur and the tendons of the adductor muscles.

CASE IX.—Josephine G., 7 years of age, was admitted into St. Mary's, Feb. 19, 1876, with disease of the right hip-joint of some duration. Family history bad. She is a sister of Amanda G. (Case IV.); her father died of phthisis. She has a fair skin, light hair. A brace was applied, and she was about the hospital, seeming quite comfortable. She rested well at night. In Jan., 1877, there was found an elastic swelling over the trochanter major. On aspirating, it was found to contain a light straw-colored fluid, resembling synovia, or the contents of a bursa.

Feb. 16.—The swelling has greatly increased, and about $\frac{3}{4}$ iv. of purulent matter was removed with the aspirator.

Feb. 23.—Patient to-day etherized, an opening

made just behind the trochanter major, and about $\frac{5}{8}$ viii. of pus evacuated. The cavity of the abscess was found to be very extensive, and to run up behind the trochanter towards the joint. The movements of the joint were smooth. A small piece of bone was found in the abscess.

March 20.—Since last date there has been considerable pain on pressure over the femur, more marked above the middle third, followed later by swelling, and an abscess (periosteal), which was opened at about the middle of the thigh. Crepitus could be detected on abducting the limb, when fully extended. Patient was losing ground. The liver was slightly enlarged. The joint was to-day excised. Section was made above the trochanter minor. The head of the bone was denuded and carious, as well as the upper border of the acetabulum; the ileum above and continuous with it was also diseased. The bone at the point of section was diseased, but on account of the condition of the patient it was not deemed safe to attempt any more. On microscopic examination of the cut section, the cancellous tissue was found filled with pus and oil-globules (osteomyelitis).

Dec. 14.—Patient's general condition improved after the operation in all respects. The amount of discharge diminished, although it never entirely ceased. She was up and about with a long splint, walking some distance without any inconvenience. The liver continued to enlarge.

In January, 1878, another abscess was opened on the outer aspect of the thigh.

March 7.—To-day she was seized with intense pain in her stomach.

March 8.—T. 104° ; pulse 160. When seen this a.m. she was vomiting; face pinched, and she complained of pain in her abdomen, which is tender on pressure, and tympanitic. Ordered morphia every hour.

9 p.m.—T. 102° ; pulse 120; respiration 36; is sleeping.

March 9.—Patient continued to fail, and died this morning.

Post-mortem.—*Abdomen*: On opening the abdomen the intestines were found to be perfectly white, as though they had been bleached, and on first inspection there did not seem to be any effusion; but on close examination the omentum and intestines were found to be covered with a creamy substance; but they were not glued together. There was considerable turbid serum in the peritoneal cavity. There was no perforation.

Liver greatly enlarged.

Kidneys enlarged and flabby; their surface irregular.

Femur did not present anything abnormal. The periosteum seemed to be healthy, and firmly attached to the bone. There was caries about the acetabulum, but not very extensive. There was also considerable bony growth on the ilium.

CASE X.—Frances M., aged eight years, was admitted into St. Mary's Hospital, July 14, 1877, suffering from hip-joint disease in the third stage. Her brothers and sisters are healthy, as well as her parents. Three years ago she had scarlet fever, followed by an abscess in left breast. Five months ago patient began to walk lame. This difficulty in going about has gradually increased, so that for the past six weeks she has not been able to walk. During the last four weeks she has had starting pains at night, and has lost much flesh. For the past week there has been considerable swelling of the thigh. Patient is pale, rather thin, and not a healthy-looking child. Has disease of the right hip-joint, with a large abscess on the outer and

anterior aspect of the thigh. There is marked crepitus in the joint.

Shortly after admission the abscess was aspirated, and in August was freely opened.

Sept. 18.—As the patient seemed to be losing ground, the joint was excised. The upper rim of the acetabulum was deeply eroded. The head of the bone was diseased; the cartilage was completely detached, except at one point, and simply covers the head like a cap. The bone under it showed marked signs of osteitis. Section was made above the trochanter minor. At this point the bone was healthy. Wound united, except opposite the acetabulum. Drainage tube inserted, and limb bandaged.

By the middle of October the wound had closed, except a small sinus, from which there was a slight discharge. Later, as there seemed to be some retention of pus, the sinus was dilated, and it was then found that the shaft of the femur coming in contact with the upper border of the rim of the acetabulum did not allow a free exit for the pus. The rim was also slightly carious. This was scraped, so as to allow a drainage-tube to be inserted. In May the tube was discontinued, and the sinus soon closed.

Patient was discharged October —, with the wound sound; no sinus. She can flex, extend, abduct and adduct, and rotate the limb. Shortening, three-quarters of an inch.

Case XI.—James F., aged five years, was admitted into St. Mary's Hospital, October 24, 1877, suffering from hip-joint disease in the third stage.

His parents are healthy. He became lame when two years of age, and seemingly recovered. After a time he again became suddenly lame.

In January, 1875, an abscess formed. At time of admission there was a profuse discharge from several openings about the hip-joint, and in the upper part of the thigh. He was much debilitated from the constant discharge.

No albumen; no enlargement of the liver.

Dec. 7, 1877.—He was etherized, and the joint excised. All the tissues were separated from the trochanter major, and the head had almost entirely disappeared. The shaft below the trochanter was so soft that a probe can readily be thrust into it. The periosteum was easily detached. Section was made at about the union of the middle with the upper third. The bone at the point presented the same softened condition. A second section was made a little lower down, but only to find the bone diseased. On one side the compact tissue seemed to be more invaded by this softening process than on the other, where the bone seems harder. The bone about the acetabulum was extensively diseased.

Dec. 11.—Discharge much lessened. Patient's appetite has improved, and he has gained in flesh.

March 26, 1878.—Patient continued in fair condition for some time; then he began gradually to fail, and to-day died of pure exhaustion. For some time back the limb has been getting stiffer, and there has evidently been considerable reproduction of bone.

Post-mortem.—There is found to be a reproduction of bone from the point of section just above the middle of the thigh to the acetabulum, over three inches. There is extensive disease about the ilium.

Remarks.—I desire, in connection with the above cases, to draw attention to the cause of death in disease of hip-joint; (a) *tubercular meningitis*; (b) *amyloid degeneration*; (c) *exhaustion*.

Case VIII. died from tubercular meningitis.

Case IX. died directly from peritonitis, secondary to amyloid degeneration.

Case X. recovered, and case XI. died from pure exhaustion.

Tubercular meningitis is not an unusual cause of death in hip-joint disease. It may occur at any time in the course of the joint trouble. Thus, a few years ago I lost a child, five years of age, suffering from coxalgia in the second stage from this complication. That this form of meningitis is one of the manifestations of the tubercular diathesis is too well recognized to require any further notice, except that its frequent occurrence in the course of hip-joint disease points strongly to a constitutional element in the causation of the latter trouble.

Case IX. died directly from peritonitis, secondary to amyloid degeneration of the liver and kidneys—a recognized termination of the latter disease. (Grainger-Stewart, Dickinson, Bartels.)

In this connection I desire to draw attention to Case XI., where death was due to pure exhaustion. The enlargement of the liver in the first case (IX.) came on several months after the formation of an abscess, while in the latter case (XI.), although the patient had suffered for *three years* from profuse suppuration, yet the abdominal organs were not affected, the patient dying from *pure asthenia*. If amyloid degeneration is due to suppuration alone, why should it appear so early in one case, and not at all in the other? I have a patient at present under my care where the enlargement of the liver was coincident with the appearance of a large abscess.

If we look a little further into the histories of these patients, we find: that Case IX. was a sister of Amanda G., Case IV.; they both had fair skin, light hair, and that peculiar cast of features that belongs to the strumous diathesis, so called; and that their father died of *pyritosis*. The patient in whom the enlargement of the liver was coincident with the formation of an abscess, lost his father from *acute phthisis*, whereas Case XI. gives a *good family* history as far as relates to tubercular tendencies.

Bartels, in his article on amyloid degeneration, in Ziemssen's Cyclopædia, Vol. XV., page 498, states that amyloid degeneration of the kidney "is invariably the local manifestation of a general constitutional disease;" and again on page 499, "as such constitutional predisposing anomalies, I may specify scrofula, chronic tuberculosis, inveterate and hereditary syphilis." Amyloid degeneration has followed suppuration in Cases II., V., VI., VII., IX., and XII.; in all of these cases there was an hereditary history of tuberculosis. In Case I., although the disease had lasted *six years*, and there had been profuse and long-continued suppuration, no change in the liver and kidneys could be discovered, and he made a perfect recovery after the diseased bone had been removed. There was *no* history of tubercular disease in the family. Case X. gave a good family history, and made a good recovery. Case III. died from phthisis; I regret that I have no record of the state of the liver. Gibney, in his paper on "The Strumous Element in the Etiology of Joint-Disease" (*New York Medical Journal*, July and August, 1877), comes to the same conclusion. Dickinson, in his work on "The Pathology and Treatment of Albuminuria," London, 1868, page 172, states "that depurative disease of the kidney is not necessarily connected with the tubercular or any constitutional taint;" yet of the five cases reported in illustration of the disease, in three the disease followed suppuration in connection with bone trouble in patient giving a *tubercular family* history, and two gave a history of syphilis.

Grainger-Stewart, "Bright's Disease," 191, etc., re-

ports six cases connected with the tubercular diathesis. From a careful study of my own cases I am forced to the conclusion that the tubercular diathesis is a, if not the, predisposing cause of amyloid degeneration in suppurative disease of the hip-joint. A review of fatal cases of joint disease, scattered throughout the medical journals, confirm me in the opinion above expressed. I do not wish to be misunderstood. I do not state that hip-joint disease in patients of a tubercular diathesis is *always* followed by amyloid degeneration, but I desire to express the opinion that it is seldom found except in those of the above diathesis. It would seem, then, that the question of the treatment of suppurative coxalgia cannot be separated from a consideration of the possibility, nay more the probability of the occurrence of amyloid degeneration in patients of a tubercular diathesis.

Medical writers speak very discouragingly of the treatment of amyloid degeneration. Thus Stewart, in reply to the question, "Is it ever recovered from?" states: "No case is on record in which so happily an event has occurred, but I have seen several in which the symptoms were well marked, and yet signal improvement took place," page 179.

It is true that these changes may occur independent of any suppuration or disease of bone, yet they are too often seen to follow chronic purulent discharge to permit us to ignore it as an exciting cause of this very serious complication.

If we are correct in ascribing death, in the majority of cases of suppurative coxalgia, to amyloid degeneration, the question naturally arises, Can we do anything to prevent its occurrence? We cannot cure it.

Murchison, in his work on "Diseases of the Liver," makes the following statement in speaking of the preventive treatment: "First and foremost, it is always advisable to arrest as early as possible copious suppuration from any part of the body, and in particular from diseased bone;" all other writers upon the subject express the same views. The preventive treatment of amyloid degeneration, then, is to reduce or stop suppuration as soon as possible.

It is claimed by those who decry operative interference in cases of disorganization of the joint, with carious and necrotic bone, that the results of excision in these cases are not as good as after strictly mechanical treatment; that the rate of mortality is due to excessive suppuration incident to the operation, and that excision does not stop the disease.

In order to form sound conclusions in regard to the treatment of hip-joint disease, mechanical or operative, a practical knowledge of *first*, mechanical treatment, *secondly*, of excision, is requisite.

For how can one criticise an operation of which he has no practical knowledge?

Excision does not as a rule increase the amount of suppuration, at least I have not found it so in an experience with twelve cases. In all, there has been a decided improvement in the general condition of these patients; they have slept better, their appetite has improved, they have increased in flesh, and they have had a better color. It is true that this improvement has not, in some cases, lasted for more than a few months. If, then, there has been a marked amelioration in their condition, lasting for months, on what fair grounds can the operation be said to have been the cause of, or to have hastened a fatal issue? The truth would seem to be, that these patients die not *from*, but in *spite* of the operation.

Another objection is, that the operation does not stop the disease. Does mechanical treatment? It is claimed that the results of excision in these cases are

not as good as after strictly mechanical treatment. In order to compare the results of any two modes of treatment, one of the first requisites is the comparison of the termination in similar cases. I have been unable to find, after a careful search through the medical journals, any account of the result of mechanical treatment in cases where there was carious or necrotic bone in the joint. It is true that at a recent meeting of the Surgical Section of the Academy of Medicine (MEDICAL RECORD, April 13, 1878), Dr. C. F. Taylor presented some statistics; and as they seem to be the only ones available, I desire to refer to them. He says: "Out of 94 cases of morbus coxarius, three had died from the disease, a rate of 3½ per cent. In a certain sense these were *selected*, because he would not undertake the treatment of any case unless he could have it under his exclusive control. The representation, therefore, is *better than it would have been* had it been based upon *all cases* which *applied* for treatment. . . . Twenty-five had abscesses, either extra- or intra-articular; of the suppurating cases, two, or eight per cent., died. . . . Dr. Taylor remarked that he had no right to report, except upon the cases which remained under observation."* The questions naturally arise, How many cases passed from under his control? What was their condition when they ceased attendance, and what has been their termination? Of the twenty-five suppurating cases, how many had *intra-capsular* abscess, and in how many did there exist carious or necrotic bone; and of those passing from under his control, how many belonged to the latter class? It would also be interesting to know what the expression, "in a certain sense these were selected," means, and what class of cases were excluded. If those gentlemen who are advocates of a strictly mechanical treatment will give us some reliable statistics of the results in advanced stages of hip-joint disease, so that the facts can be known, much will be done to advance our knowledge of the treatment of hip-joint disease, and the claim that better results are obtained in these cases by mechanical treatment than by operation, will rest on broader ground than a mere statement, unsupported by scientific evidence.

I cannot see that the gentleman's statistics afford us any aid. In a paper read before the Journal Association by Dr. C. F. Taylor, February 1, 1878, he asks the following question: "Could excision be depended upon, and could any determinate result be expected by its performance?" With equal force the question might be asked, Could strictly mechanical treatment be depended upon, and could any determinate result be expected from its continuance after the joint has become disorganized and carious, or necrotic bone is present?

The real question seems to be, does excision improve the general condition of the patient; if it does, it certainly gives him a better chance to recover, and on this hinges the advisability or not advisability of operative procedure. If suppuration from carious bone is profuse, notwithstanding mechanical treatment, we must expect in a certain class of cases, changes in the abdominal viscera; and when it can be proved that mechanical treatment is able to cure amyloid degeneration, then, and only then, can the question of excision be dismissed from our consideration.

The reproduction of bone after excision is sometimes astonishing, even in those cases that terminate fatally. Thus in Case XI. there was fully three inches

* The italics my own.

of bone reproduced, notwithstanding the debilitated condition of the patient.

A reference to the case of Rosa Mullen, reported by Dr. Sayre, is also one in point as illustrating the fact that a patient may recover after exsection, yet die from amyloid degeneration long after. The question raised by Dr. Taylor in regard to this case, "What right had a surgeon to assume such wonderful reproductive power would not take place under other forms of treatment as well as after excision?" is not to the point unless it can be demonstrated that the tendency is towards recovery in extensive disorganization of joint with the presence of grave bone lesions. The fatal termination in this case was not from hip-joint disease, but from constitutional trouble. I have seen osteophytes about a diseased joint, but I am not aware of any specimen illustrating any marked reproduction of bone or any significant attempt at repair while there was present carious bone in the joint, and I do not think that an inspection of the pathological museum will show one. As long as there is dead bone in a joint, so long will suppuration continue, and until the irritation of its presence ceases, reproduction cannot go on. As soon as there is dead bone in a joint the articulation as a joint is destroyed, and the general rules of surgery are as applicable to it as dead bone in any other situation.

Quite recently my friend Dr. Gibney showed me a specimen removed from a boy sixteen years of age, with a tubercular family history, who had had disease of the hip-joint, and had recovered with ankylosis, but who had died from amyloid degeneration. The head and neck have disappeared, and the shaft of the femur was fused with the acetabulum. A word in regard to recovery from amyloid degeneration. In a former paper I expressed the opinion that James C., Case VI., who had an enlarged liver, and albumen in his urine before the operation, would not recover. It is now two years and a half since the operation; the liver is now reduced to almost its normal dimensions, he has regained a good color, and his general condition is excellent. I am not prepared to claim that this is a case of recovery, but shall watch it with interest. There has certainly been a marked improvement.

In the *Lancet* for November 2, 1878, a case is reported by Mr. Gay, where the liver diminished to its normal size, and albumen disappeared from the urine, after secondary amputation at the hip-joint subsequent to exsection.

To recapitulate, cases I., II., VI., and X. are alive. Nos. I. and X. have recovered. No. VI. has recovered as far as the joint is concerned, and the liver has almost assumed its normal dimensions; still I mark it doubtful.

No. II. is alive, but with no prospects of recovery.

No. III. died from phthisis.

No. IV. from heart clot?

No. V. amyloid degeneration.

No. VII. " "

No. VIII. tubercular meningitis.

No. IX. amyloid degeneration.

No. XI. from pure exhaustion.

Not any of the fatal cases, except No. IV., died from causes connected with the operation, nor do I think that the fatal termination was in any way hastened by it. In those that recovered I do not think, from the histories of these patients and the course of the disease while under my care, that a cure was probable without exsection.

The following conclusions may be drawn from the above:

1st. That the causes of death directly traceable to coxalgia are amyloid degeneration, tubercular meningitis, and exhaustion.

2d. That there is an intimate connection between the tubercular diatheses and amyloid degeneration, so that those of this predisposition seem peculiarly liable to this complication subsequent to suppuration in connection with diseased bone.

3d. That exsection does not, as a rule, increase the amount of suppuration.

4th. That death is not as a rule due to, or hastened by exsection.

5th. That the removal of carious or necrotic bone from the hip-joint is followed by an improvement in general condition of the patient, and that the chances of his recovery are improved thereby.

6th. That in patients of a tubercular diathesis, the question of excision should earlier be taken into consideration than in those of a non-tubercular diathesis.

7th. That repair in a joint after excision is no proof of the non-existence of amyloid degeneration.

REMOVAL OF A PESSARY FIRMLY IMBEDDED IN MUCOUS AND FIBROUS TISSUE.

By FRANKLIN B. SMITH, M.D.,

FREDERICK, MD.

It is an every-day occurrence for a practitioner to be called upon for the relief of uterine trouble, to apply a pessary and leave the patient go her way without caution or instruction, maybe never to be seen by the same medical man again. One of the injurious consequences of this practice is well exemplified in the following case which lately came under my charge, and which for its practical teachings deserves publication:

M. D., a woman *etat.* 35 years, was compelled to stop work on November 1, 1878. On the 20th, being called, she was found suffering with the following symptoms: dragging and sense of weight in the pelvis, inability to do hard work or to walk any distance without provoking colicky pains in the abdomen, difficulty and pain in micturition. On examination the uterus was found prolapsed, the os appearing at the vulva, while encircling the uterine globe opposite the pubes appeared a firm, hard, constricting band of mucous membrane projecting from the vaginal walls. This was the case anteriorly and on the sides, but upon being traced back ended in the free surface of a retroversion pessary. The uterus was now with some difficulty pushed above this and a more careful examination made. The whole anterior and lateral portions of the pessary were covered with or embedded in the mucous membrane of the vagina, and resisted any movement.

As the pessary had moved somewhat from its original position, had lost its use and prevented any treatment for the prolapse so long as it remained, I decided to remove it.

On November 21st I cut off the posterior portion of the pessary, by means of a pair of bone-pliers, in the vain hope of being able then to withdraw the remainder by simple traction on one of its ends, but in this I was disappointed. The pessary opposite the pubes was deeply and firmly embedded, not in mucous, but in fibrous tissue, nor could it be moved the slightest particle. A bivalve speculum was then introduced, and in it I held a laryngoscopic mirror; then with a lancet, the flamm of which was at a right angle to the

handle and stem, cut directly down upon the pessary, rotating the interspace between the valves as I cut. In this way I succeeded in exposing the pessary throughout its whole extent, except just at the pubes, where the anterior portion of the pessary (an Albert Smith's) was so deeply embedded as to resist all the force I could in this disadvantageous manner bring to bear upon it. The patient being tired and worried out with the pain, and considerable time having been expended, I desisted, determining to resume under other the following day.

On the 22d, with the assistance of Dr. Charles Smith, after the patient had been anesthetized, while one of the ends of the portion remaining was firmly held by means of a sequesterum forceps, I carried the lancet guarded by my fingers into the vagina until it rested upon the resisting bands. These, after some difficulty, were severed, when, after some traction, the anterior portion was removed. The instrument proved to be an Albert Smith hard rubber retroversion pessary, remodelled by lengthening at the expense of its width. It was the anterior portion which had first caused the ulceration and subsequent embedment. The only history obtained was that four years ago she had suffered with "womb disease," had applied to a physician for relief, had been relieved, and had suffered but very little from that time until lately. The patient did well, and subsequently was treated for the prolapse.

A FILARIA IN THE EYE OF A HORSE.

By CHARLES J. KIPP, M.D.,

NEWARK, N. J.

ABOUT a year ago I was requested by Veterinary Surgeon Lawrenz, of this city, to see with him a horse which, as he said, had a live worm in one of its eyes. I hastened to the place, and, to my great astonishment, found the case as represented.

The horse was estimated to be over twelve years of age, and was in good condition. From the owner I learned that he had first noticed a slight inflammation of the eye about six weeks before. Two weeks later a "film" came over the eye, and, on closer examination, a white worm, about an inch long, was seen wriggling about in the eye. Since then no marked change has occurred.

On examination, the eye was found to be intolerant of light, and apparently blind. The ocular conjunctiva was injected, and the entire cornea was so hazy that the texture of the iris could not be made out. The epithelial layer of the cornea was perfectly smooth and regular. The pupil was contracted and inactive; but no posterior synechie could be made out. The anterior chamber was very deep, and in the aqueous, which was slightly turbid, was seen a white, cylindrical worm, apparently about seventy-five (75) millimetres in length, and of about the diameter of a violin-string. The worm was in constant violent motion. The tension of the eye was apparently somewhat increased, as compared with the sound one.

I proposed to make at once a paracentesis of the anterior chamber, for the purpose of removing the worm, but, at the request of the owner of the horse, deferred the operation for several days. At the next visit the eye was found to be still in the condition described. I then, in the presence of a number of physicians, made, with a straight, lance-shaped knife, an incision about four millimetres in length in the outer half of the cornea, about midway between the centre and the periphery, and, on withdrawing the

knife, the aqueous, and with it the worm, escaped from the eye. I ordered the horse to be kept in a dark stable; applications of cold to the lids, and instillations of a one per cent. solution of sulphate of atropia. Of the subsequent history of the case I have no personal knowledge, as I have not seen the horse since; but from Dr. Lawrenz, who saw the animal again some six months ago, for the first time since the operation, I have recently learned that the owner disregarded our advice, and drove the horse some twelve miles immediately after the operation; and that, although no inflammatory reaction followed the operation, the eye has gradually become atrophic.

The worm was placed in a warm, weak solution of salt, and kept alive for nearly twelve hours; since then it has been preserved in weak alcohol. It was my intention to submit the parasite to an examination by an expert in helminthology, immediately; but the matter was entirely forgotten till a few weeks ago, when I saw an article on "Filaria in the Eye," by Dr. Charles S. Turnbull, published in the *Philadelphia Medical and Surgical Reporter*, October 26, 1878. Since then Prof. J. C. Dalton, of the College of Physicians and Surgeons, New York, has had the kindness to examine the worm, and his report is as follows: "The parasitic worm you left with me for examination is cylindrical in form, and of a white color. It is 65 millimetres long, and 0.3 millimetre in diameter. The head is bluntly rounded; mouth terminal, with several small surrounding tuberosities. The specimen is a male, with the tail obtusely conical and twisted in two and one-half spiral turns. There is one very long copulatory spicule. I could not distinguish a second one, nor any membranous expansion or envelopes about the generative organs. With these two last exceptions, the characters of the worm are those belonging to the genus *Filaria*; but I cannot determine its species, and doubt whether it has been fully described in any of the standard works on herminthology."

The parasite was exhibited by me to the members of the New York Ophthalmological Society, at the meeting in January, 1878.

Filaria in the anterior chamber of the horse are very frequently seen in some parts of India (Macnamara, *Diseases of the Eye*, 3d Ed., London, 1876, p. 356); and Sichel, *père*, has seen many cases of the kind in Europe (*Compte-Rendu du Congrès Ophthalmolog. de Bruxelles, par Warlemont*, Paris, 1858, p. 155).

In this country this disease appears to be of rare occurrence, judging from the very small number of cases on record. Dr. Turnbull, in the paper already referred to, says that he made a diligent search through the American journals, and found the record of but a single case; to this he adds one observed by Dr. Corbyn, and another recently seen by himself.

In only one of these three cases (Dr. Corbyn's) was the worm removed from the eye; but no anatomical description of the parasite has been placed on record.

With regard to the manner in which the worm enters the eye various theories have been advanced, the most plausible of which assumes that the ova, found in the stagnant waters of India, and doubtless also in this country, find their way into the animal's body with the water he drinks, and are then carried with the blood into the eye.

Macnamara (*Op. cit.*, p. 356) says that entozoa in this situation excite violent inflammation of the iris and cornea, and probably abscess of the eyeball, unless they are allowed to escape from the eye. This may usually be effected without difficulty by puncturing the cornea with a narrow-bladed knife, which

is rotated edgeways as it is withdrawn from the eye, allowing the aqueous to escape with a gush, and with it the entozoa.

In the human eye a similar parasite has been seen twice in India by Macnamara (*Indian Annals of Medical Science*, No. XVI., p. 405), and a few doubtful cases are recorded by Quadri, Mauthner, and Davaine. No case of the kind has been published in this country.

Reports of Hospitals.

BELLEVUE HOSPITAL.

PNEUMONIA: NOTES ON MORTALITY, TREATMENT, ETC.

HOSPITAL pneumonias form a class of diseases especially liable to elude statistics regarding fatality and treatment. At least this is the case in the city hospitals of New York. The patients affected are of many nationalities and have been subjected to an infinite variety of, in general, bad hygienic conditions. Probably Bellevue receives about as bad a set of cases as any institution. The histories of these cases, however, furnish a good many interesting facts, especially as it is of acknowledged importance to study the local characters of acute diseases.

The majority of the patients brought to Bellevue trace their pneumonia to exposure. Sometimes this has been the sequel of alcoholic excesses; but it is not often so, and there must be innumerable debauches under unhygienic conditions that are not followed by this disease. If there is one well-determined cause, it is immersion. Every interne can relate the histories of patients who have fallen or thrown themselves into the water, have been fished out, brought to the hospital, and next day have developed pneumonia. It is difficult to say how the "germ" of the infectious disease pneumonia happens to get into the system so patly with the immersion. It is asserted that the pneumonia is catarrhal in these cases, or that the system was already infected, or perhaps the germ is amphibious.

It is not rare for hospital pneumonias to be complicated; but, as complications themselves, they are not often seen. Out of nearly a hundred cases occurring within the past two and a half years, twenty-two had complications, while six more were double pneumonias, and eleven were eminently alcoholic in cause and character.

At least three times as many males as females are admitted with the disease. Among 96, only 27 were females. The patients come in on the third or fourth day of their sickness, and the majority of them are between the ages of 30 and 50 years.

In regard to the mortality of the patients with pneumonia, and its causes, the histories of hospital-cases are of considerable interest. It is well known that the percentage of mortality varies in different years, in different climates and epidemics, and possibly under different treatments. There are statistics giving death rates of only .03 or .05 per cent. The more common ones run up to from .14 to .24 per cent. Bellevue Hospital presents the exceptional pathological advantages of a death-rate somewhat larger still, amongst over a hundred cases that occurred within the past two and a half years.

Of the 29 who died, 8 had complicating diseases, while 5 were alcoholic cases, and 3 were double pneu-

monias. This would perhaps account for the mortality in sixteen. On the other hand, of those who recovered, 16 had complications, many of them quite severe. Besides these there were 6 alcoholic cases and 3 double pneumonias which recovered, making in all 25 patients who were brought through conditions especially serious.

The mortality was somewhat greater among the males than the females, being three or four per cent. more for the former.

The date of admission was about the same for those who recovered and those who died. This appears somewhat strange, as the patients nearly all keep at work or lie neglected and exposed till the disease is well on them, and this is generally reckoned a factor in the death rate.

The largest number of cases (32) were between the ages of 30 and 40; the largest number of recoveries were also in that decade. The largest mortality was between the years 40 and 50. Ten of the deaths occurred then, which is nearly twice as many as in any other decade.

The pneumonias were located most frequently in the left lower lobe. There were 27 there to 19 in the right lower lobe. On the other hand, there were 10 in the right apex to 3 in the left. The sufficiently well-established fact that apex-pneumonias are the most dangerous is confirmed here. Of 13 apex cases, 5 died; of 48 where the disease was at the base, 12 died.

The great mortality at Bellevue is due largely to the character of the cases sent there. They are often persons saturated with alcohol, and prostrated with neglect. It could hardly be from the complications directly, for only two or three had such as have not been recovered from often. Neither could much be laid to the treatment, for it is not dangerously experimental, so that it is difficult not to refer some of the mortality to the malignancy of the disease. Patients come in trembling with alcohol, wandering in mind, with high fever, and, perhaps, pleurisy complicating, or with the pneumonia double; yet they get well. At other times, persons who have been strong and temperate, wilt down before the disease in forty-eight hours. There is something almost appalling in the way with which at times case after case is attacked and succumbs. The fever is not very high, the lung not extensively involved; it is impossible to suppose that the heat has paralyzed the heart; yet the heart does become paralyzed, edema of the lung comes on, and death ensues.

On only one post-mortem is there a record of an anti-mortem clot in the right heart. In this case the thrombus was diagnosed, and death predicted twenty-four hours before its occurrence.

Ten years ago pneumonia was quite uniformly treated with carbonate of ammonia internally and an oil-silk jacket externally. The carbonate was given in doses of gr. v. every three hours, or sometimes gr. x. three times a day. The muriate was occasionally substituted. Gradually quinine came to be combined with the ammonia, while now quinine has quite taken its place in many wards. The quinine is given in doses of gr. x. three times a day, increased or diminished according to the fever. The oil-silk jacket is still continued, and if there is much pain in the side, a coat of iodine is ordered. This, with an absolutely recumbent posture, is all that is enjoined in many cases. Aconite has been used in five cases, of which one died. It is given in doses of ℥i. every hour, till some effect of the drug in relief of dyspnea, fever, or production of sweating is produced.

In forty-four cases quinine was used with good results. The method of administration is varied. Besides the routine mentioned, it is given gr. i. every hour, or gr. v. every four hours, and often, as directed by the Juergesen, gr. xl., or gr. l., in one dose, then discontinuing it for a day or more. The antipyretic effect of quinine is not sufficiently marked to have made it clear which is the best way. Cold sponging has been employed with quinine. Of seven cases so treated, three died. The gradually cooled bath has been used, and at once given up.

Owing to the previous bad habits and bad condition of the patients, as well as to the frequent virulence of the disease, the treatment of many cases of pneumonia soon resolves itself into the treatment of exhaustion, œdema of the lungs, and a nearly moribund condition.

How to carry a patient through critical conditions of this kind, how much stimulus, and what kind, are matters that text-books do not give very definite accounts of, and experience has generally to become the teacher.

Many cases that come into the hospital have a record like the following: The patient is a tolerably strong man, in the third day of the fever. He has a temperature of 104°, respiration 50. His pulse is very good, and he feels pretty comfortable. He is given milk and eggs, and gr. xv. of quinine. This is in the morning. In the afternoon he is weaker, his face is a little blue, he breathes faster. On listening to the lungs, moist râles, fine and coarse, are heard. He is beginning to have œdema. He is at once dry-cupped for fifteen or twenty minutes, during which time 150 cups are put on. The œdema has now disappeared. He is ordered ℞. of *tr. digitalis* every three hours, and ℥ss. of whiskey every two hours, with milk and eggs. He continues better for some hours. Towards evening the œdema again shows itself. He is again cupped, and gr. x. ammon. carb. is ordered every two hours, alternating with the whiskey. Again the œdema clears up. In addition, a can of oxygen is ordered for the night, and the patient inhales it for fifteen minutes in every hour. This relieves his dyspnoea. But towards morning the cyanosis and œdema again appear. The cups are applied again, and the whiskey ordered, ℥ss. every hour, alternating with the ammonia, gr. x., every hour. By these measures he is carried through the night, and in the morning is easier. Nourishment in the form of milk is still kept up. He is not allowed to sleep continuously, for during sleep the œdema comes on. By such fighting as this, the greatest reliance being placed on whiskey, milk, and dry cups, a patient is occasionally brought through. If, on the following day, he is still worse, the resources in the way of stimulants are not exhausted. Other forms of ammonia are used. Hypodermic injections of camphor dissolved in sweet oil are given every three hours in four-grain doses. If the patient has persistent œdema and a full pulse, venesection is tried, and is invaluable when digitalis and cups no longer avail. The oxygen cannot be pushed too much, as it causes unconsciousness.

Hypodermic injections of ether to the amount of one or two drachms sometimes bring up the pulse. Teaspoonful doses of champagne every five minutes will help to tide a crisis. There is a limit to stimulation, of course. When ℥ss. of whiskey every half-hour has no effect the patient will die. There is no use in increasing the amount unless it is desired to preserve the stomach afterwards. In the case of a man to whom ℥ss. q. ¼ h. was given for several hours,

the stomach was found at the autopsy to be considerably hardened by the alcohol and to smell strongly of it.

In spite of all efforts, most of the cases in which œdema of the lungs occurs go on from bad to worse. The extremities become cold and wet with perspiration; hot bottles applied to them and to the breast, mustard to the epigastrium, accomplish only temporary good, the patient has long been stupid; he now loses consciousness, his breath is slow and labored, the air-passages are full of serum; gradually the respirations grow slower and slower, and finally stop. The patient dies. At the autopsy part of the lung will be found to have reached the stage of gray hepatization.

It will be seen that no new or specific treatment can be deduced from these cases. It has become a firmly rooted belief that quinine is a good thing to give, and in those so treated the mortality has been somewhat diminished. The class of patients is not one upon which cardiac sedatives can be fairly tried.

Progress of Medical Science.

BATTEY'S OPERATION.—An unsuccessful case of this operation is reported by Dr. Preece, of Jacksonville, Ill. The procedure was proposed for the relief of hystero epilepsy, from which the patient had been suffering for eighteen months, and which was gradually destroying her mental balance. The girl was eighteen years of age, and was apparently healthy up to the inception of this trouble. The paroxysms could be partially or completely controlled by pressure of the hand in the iliac region, at first upon the left side, later upon the right. The operation was performed according to Battey's original plan, by an incision through the vagina. The ovaries were brought down without any difficulty, and their attachments divided by the galvano-cautery; no bleeding following. Immediately after the operation the patient was put sufficiently under the influence of opium to control the spasmodic manifestations. Next morning there was vomiting, which appeared again in the evening, this time of a spinach-green color; pulse 140, temp. 101½°; morphia continued. On the third day, temp. in axilla 106°, in rectum 108°; pulse 160; breathing stertorous; eyes divergent; unconscious. She died towards the end of the fourth day. At the autopsy only the abdomen and pelvis were examined. "There existed about an ounce of blood coagulum (without odor) in the pelvis. There were no indications of pus or false membrane, and no coloration as would occur from inflammation. The incision in the vagina had healed by first intention. The death was, therefore, neither by inflammation nor by poisoning, but probably by the exhaustion of a hystero-epileptic acmé."—*The Obstetric Gazette*, December, 1878.

THE USE OF THE MIDWIFERY FORCEPS.—In applying the forceps to the fetal head above the brim, but little attention is ordinarily given to the manner of seizing it; most practitioners believing with Barnes that it makes, practically, but little difference to which diameter the instrument is applied. Dr. Whitehead, of Denver, however, maintains that in shortening of the conjugate diameter of the mother's pelvis, judiciously-timed compression of the bi-parietal diameter of the child's head will frequently obviate the necessity of resource to craniotomy; and, moreover, as compression of the oblique or occipito-frontal di-

ameter would only serve to increase the bi-parietal, he urges the conclusion that the only safe use of the forceps for the child above the brim is in seizing and fixing the head until it engages. Much of the hard pulling so often required in cases of simple uterine inertia in normal pelvis to draw the head through the brim, is largely due, he thinks, to the oblique seizure of the head. Especially should a powerful compressive instrument, such as Hodge's or Wallace's forceps, be used. He has always given the preference to Simpson's forceps.—Reprinted from the *Transactions of the Colorado Medical Society*, 1878.

ANALYSIS OF ONE THOUSAND CONSECUTIVE MIDWIFERY CASES.—Dr. Thomas Newman publishes in *The Lancet* (December 14, 1878) an analysis of one thousand consecutive cases of child-birth, occurring in an agricultural district. Of the total number of children born (1013), 518 were males and 495 females. Twins occurred nine times; triplets twice. The breech presented in fourteen cases; the arm in two; the face and the feet, each in six; the head and one hand nine times. The placenta was adherent in eleven cases; two cases of hour-glass contraction speedily yielded to chloroform. Forceps were used thirty-three times, being rendered necessary in two cases (mother and daughter) by contraction of the brim; in five (primiparæ) by the large size of child; and in the rest by failure of expulsive pains when the head was at the outlet of the pelvis. In no case was there any excessive hemorrhage, which is attributed to the influence of ergot. This drug was given in drachm doses of the fresh powder, stirred up in warm tea, and has been administered in fully one-third of the cases. There was no death from purely puerperal causes. Rupture of the perineum occurred only to a slight extent, in no case requiring any other treatment than keeping the legs well together for a few days.

HYPODERMIC INJECTION FOR PILES.—Prof. Andrews, who first gave publicity to this method of treating piles, has requested, through the pages of the *Michigan Medical News*, the details of any evil results following its use. Communications should be addressed to Edmund Andrews, M.D., No. 6 Sixteenth Street, Chicago.

CHRONIC CYSTITIS.—A case of chronic cystitis, occurring seven years after an operation for lithotripsy, is reported by W. F. Teevan, F.R.C.S., in which recovery was brought about by an exclusively milk diet. The patient took about six pints of milk a day, and at the end of a week he had lost all pain; the urine was quite clear, acid, sp. gr. 1020. A month later he still remained well, although an enlarged prostate compelled the use of a catheter twice a day.—*The Lancet*, Dec. 7, 1878.

DISEASES OF THE BRONCHIAL GLANDS.—Dr. Richard Quain has analyzed the records of sixty cases in which these glands were diseased, and has given an important contribution to their clinical and pathological history.

The pathological conditions to which they are liable, apart from tumors, are congestion, acute and chronic inflammation, tuberculous, scrofulous and syphilitic disease. Acute and chronic inflammation in rare cases leads to abscess opening into the bronchi or mediastinum. Chronic inflammation, which is rather common, leads generally to enlargement or calcareous degeneration.

Disease of the glands occurs oftener in females, and after the age of puberty. Besides the various cachexiæ, the exciting causes are the fevers, and inflammations

of the structures which contain the afferent lymphatic vessels, bronchitis, pleurisy, and pneumonia. The enlarged glands pressing on the recurrent laryngeal may excite cough.

The symptoms, in order of frequency, are as follows: cough which is generally dry, pain felt near the fourth and fifth dorsal vertebra, with tenderness on pressure, often accompanying it. Dyspnoea, sometimes equaling that of spasmodic asthma.

Dysphagia and hæmoptysis in one-sixth of the cases. The amount of blood varies, but is sometimes considerable. Expectoration of ordinary mucus was frequent; more rarely pus or calcareous particles were found in the sputa.

Aphonia and vomiting occurred in a few cases.

Congestion and puffiness of the face were noted. This, as well as the hæmoptysis, is caused by pressure on the venous trunks.

There is a position of least discomfort which each patient is apt to assume. Physical signs help in the diagnosis. Dulness in the interscapular region was present in forty-seven cases. Bronchial breathing, loud expiratory murmur and feeble breathing were each noted in about a dozen cases. Vocal resonance is sometimes increased.

The treatment has to be directed to the cause and the general condition. It is often very successful.—*British Med. Jour.*, December 14, 1878.

VAGINAL ENTEROCELE.—A very curious case of this kind has been reported by Dr. Hodgson to the St. Louis Medical Society. The patient, aged 40, mother of two children, was first observed in 1874 to have a tumor the size of a goose-egg on the left labium. It could be pushed back completely into the abdominal cavity, but returned when the patient stood up. It kept increasing in size until in four years an enormous, slightly pedunculated tumor, weighing sixty-four pounds, hung from the labium. It seemed to be composed of hypertrophied skin, of omentum, intestine, and the bladder. The patient died of pernicious malaria. On autopsy the hand could be easily passed from the pelvis into the hernial sac of the tumor. This sac contained a gallon of serum, considerable omentum, and part of the colon. The bladder formed part of the tumor, but was outside of the sac. The uterus was dragged over, but remained in the pelvis. The tumor had passed down by the left side of the vagina, nearer its anterior than posterior wall.—*St. Louis Med. and Surg. Journal*, Dec., 1878.

PROGRESSIVE MUSCULAR ATROPHY WITHOUT CENTRAL LESION.—A very peculiar form of progressive muscular atrophy is reported in the *Paris Gazette Médicale*, Dec. 14, 1878. A woman, previously healthy, was suddenly taken with high fever and severe pains in her body and limbs. By the third day the extremities had perceptibly diminished in size. The muscular atrophy continued, but the pains grew less. At the end of ten weeks she was admitted to the Hotel Dieu. There was then marked atrophy of the lower limbs, forearms, and hands, notably the thenar and hypothenar eminences. There was paresis and loss of muscular contractility just in proportion to the muscular atrophy. There was no contractions, no loss of sensibility; rectum and bladder were normal. The patient died in two weeks from a complicating pneumonia. Autopsy revealed absolutely no lesion of the brain or cord. The muscles showed the usual degenerative changes. The disease was considered one of progressive muscular atrophy of peripheral origin. Its rapid course and simultaneous implication of many muscles separate it from the ordinary form.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, February 1, 1879.

A NATIONAL HEALTH BUREAU.

THE public mind has been so much exercised in regard to the necessity of some better means of protection against epidemics than at present exist, that the way has been prepared for the presentation in Congress of bills bearing upon the creation of National Bureaus of Health.

There are now before Congress three bills having the latter object in view. The first in the order of presentation was the one known as the Lamar bill; the next is the bill of Mr. Matthews; and lastly, that which is styled the Withers bill.

As preliminary to some general remarks upon the subject under consideration, it is eminently proper that the distinctive features of each bill should be presented.

Mr. Lamar's bill contemplates the establishment at the seat of Government of a department of health, the general design and duties of which shall be to acquire and diffuse among the people useful information on subjects connected with public health, to direct the establishment of efficient sanitary and quarantine systems, to supervise the Marine Hospital Service, and to organize and direct a corps of sanitary engineers competent to superintend all public works so far as their construction may affect public health. For the general enforcement of these regulations the appointment by the President of a Director-General of Health, with a salary of seven thousand five hundred dollars, is provided for. The duties of Director-General comprise those of the present Supervising Surgeon-General of the Marine Hospital Service, and the supervision, organization, and management of the quarantines of the United States as provided by the National Quarantine Act.

This, of course, provides for the abolition of the office of Supervising Surgeon-General, and the transference of all records of his department to the new bureau. The Director-General is expected to en-

force necessary quarantine, and to carry into effect such rules and regulations as in his judgment will, with the least inconvenience to commerce and travel, prevent the spread of disease. He shall also select suitable localities for establishing quarantine stations, erect suitable temporary buildings for disinfection of passengers, baggage, cargoes, and other matters believed to convey the contagious principle of cholera, yellow fever, small-pox, and other epidemic diseases; and may enforce such transshipment of passengers, baggage, and cargoes as he may deem necessary, and shall assign a competent medical officer to each station. Provision is also made for the registration of births, deaths, marriages, etc.; the procuring of information relating to the climatic, meteorological, geological, and other conditions affecting public health; the employment of experts in special lines of investigation; of clerks and additional officers, and the transmission of a report to Congress.

There are some very commendable features in this bill; but the principal objection to it, and one which must necessarily be fatal to its passage, is the autocratic powers conferred upon the Director-General.

The bill of Senator Matthews is more comprehensive in its scope, more liberal in its aim, and more consistent with the general principles of republican government. Instead of the one-man power advocated in the previous bill, the one under consideration provides for the creation of a bureau of seven members, with a Directing Surgeon-General, who shall be the executive officer. The bureau is to be under the control of the Treasury Department. The office of Supervising Surgeon-General is to be abolished, and the duties of said officer are to be transferred to the bureau. It gives to this bureau power over all quarantine regulations, and makes the Consular service a part of its machinery. It may require Consuls in foreign ports to make weekly reports as to the health of the city or country to which they are accredited, and places special restrictions upon vessels leaving Havana and other West India ports at certain seasons of the year.

All such vessels bound for any port in the United States shall be required to obtain from a medical officer, serving in the office of the consul of the United States at that port, to be appointed by the President for that purpose, his certificate, setting forth that he has personally inspected said vessel, her cargo, crew, and passengers; that the rules and regulations prescribed by the Bureau of Health in respect thereto have been fully complied with; and that, in his opinion, the said vessel may be allowed to enter a port of the United States and land its cargo and passengers, without danger to the health thereof on account of any infectious disease; and without such certificate of said medical officer, it shall not be lawful for any such vessel to enter any port of the United States.

It also gives power to the bureau to appoint a

health officer at each port of entry, who is to have the charge and enforcement of all sanitary and quarantine regulations. For this service the bill contemplates the appointment, in a great measure, of the present marine hospital corps. The Director-General, with the advice and consent of the Board of Health, is required to correspond and co-operate with similar local officers, boards, and authorities acting under laws of the States in sanitary measures, to prevent the introduction and spread of contagious and infectious diseases from foreign countries into the United States, and from one State into any other State, by means of commercial intercourse, and upon and along the lines of inter-State trade and travel; and to that end it shall be lawful for said Board of Health and Director-General of Health to confer upon any such local officer or board within or near the locality where his or its authority is exercised, power also to enforce the provisions of this act, and any rules and regulations made in pursuance thereof.

The Withers bill is based upon a recommendation of the Executive and Advisory Committees of the American Public Health Association. It merely provides for the drawing of a plan for a National Public Health Association, to be submitted to Congress at its next session. The Public Health Association is apparently fearful of hasty legislation, and can seemingly suggest no better line of action. Its main objection urged against any present legislation is that there is a great diversity of opinion regarding many matters bearing upon general or local quarantine, and the inference would seem to be that in the course of the coming year all the difficult questions will be sufficiently settled. It is further urged in the memorandum of the Health Association referred to, that the selection of a committee for this purpose is of the greatest importance, and that consequently it should be left to the members of the National Academy of Sciences. Probably as an improvement on this suggestion, the said Academy was designated in the bill as the proper body to take the matter in hand. We cannot believe that the Public Health Association is willing to father the bill as it now stands—to leave sanitary matters to a body of gentlemen who have never given any attention to the subject, and whose studies are confined to astronomy, geology, entomology, and kindred subjects. If this Academy is qualified to decide on matters of quarantine, and is the only competent tribunal to which sanitary questions must be submitted—the only authority to be trusted in proposing a plan for a National Public Health organization—it is time the profession should make a new departure and call the so-called expert sanitarians to account. The utter absurdity of the proposition is of itself sufficient to make the defeat of the Withers bill a foregone conclusion.

The suggestion of the Health Association, that the

present state of sanitary science forbids present legislation, is a piece of presumption for which there does not seem to be any adequate excuse, except perhaps to explain why nothing was accomplished at the recent meeting in Richmond, Va. We believe that the Public Health Association is mistaken in regard to the necessity of delay. The public and the profession have lost patience in waiting for some reasonable suggestions from the Association, and have been so disappointed with the results of the last annual meeting of that body, that they are willing to look beyond the provisions of the Withers bill for help.

The President, in his message, urged immediate action, and in so doing he gave expression to the general wish of the people. The profession stands ready to endorse his propositions, and enter heartily into any scheme which may bring about the desired result. At present there is no better way of doing this than in supporting the Matthews bill. Therein are contained all the good features of the Lamar bill, with none of the objections which obtain in the bestowal of autocratic powers. Therein provisions are made for the distribution of authority and responsibility in the Board, for the enforcement of intelligent quarantine in ports of exit and entry, for reasonable local quarantine upon rivers and railroads, and for the creation of local health boards in times of emergency. There is one thing, however, which would increase the scope and efficiency of the bill—and that is the incorporation of a provision for an international inquiry into the causes for yellow fever at the places of endemicité.

THE PLAGUE IN RUSSIA.

RECENT advices state that a disease, resembling in general character and in high rate of mortality the Plague, has made its way upward toward the North and East of Russia, from the Caspian Sea along the Volga. It appears to have been imported by a regiment of Cossack soldiers, the germs of the disease having been contained in some booty from Turkey, which was carefully concealed from the quarantine inspector. When the disease first appeared it was looked upon as a severe form of typhus, and it was not until the characteristic lesions showed themselves that grave suspicions were aroused and that the government saw fit to take some steps to stay its progress. From all accounts it appears to be spreading beyond the control of the local authorities. The terror of the inhabitants of some of the towns infected is so great that large numbers have fled, scattering the disease throughout wide districts of country. The mortality has reached ninety per cent., and the type of the disease is peculiarly malignant. There does not seem to be much doubt that the latter condition is due to the late war and the attendant results of general privation and famine. What adds a peculiar gravity to the situation is the fact that Russia has a very imperfect idea

of quarantine, and is in the anomalous and distressing condition of being poorly supplied with physicians.

In attempting to read the future by the past, there is hardly any danger of the disease spreading beyond the confines of the southern and eastern portions of Russia, unless perhaps the impoverished condition of the people may make an exception to the general rule. The probability of the latter, however, causes some anxiety in South-eastern Europe, to which place the disease would spread, if anywhere, beyond Asia. During the last decades, after a long immunity, unmistakable epidemics of the disease, though of limited extent, have appeared in isolated regions of Africa and Asia. In 1858 and 1859 such an epidemic occurred among the Arabs in North Africa, another in 1857 in Mesopotamia, and one in 1871 in Persian Kurdistan. Since then until the present the disease seems to have died out. Its revival again in Asia proves that history is about to repeat itself. The distinctive characters of the disease are chill, great prostration, high fever of a typhoid type, dizziness, nausea, vomiting, accelerated respiration, and in time suppuration of the inguinal glands or the glands upon the neck or in the axilla. Death usually takes place between the third and fifth days. When there are lung complications and bloody expectoration, the term "black death" has been used to designate the disease. By most authorities the bubo-plague and black death are supposed to be one disease showing itself in different forms.

THE STATE MEDICAL SOCIETY.

THE next meeting of the State Society, which is to commence at Albany, on Tuesday, February 4th, at 10 A.M., promises to be one of extraordinary interest. Judging from the number of papers which are promised, the scientific element of the meeting will predominate over that of any other previous session within our remembrance. In the abundance and variety of the good papers which are offered, there is but one concern, and that is, the lack of time for their presentation. This condition of things would seem to indicate the necessity of utilizing all the time possible for the discussion of strictly scientific subjects. Still the legislative element of the meeting must not be ignored. The best way to meet all the necessary requirements is to have the ethical questions worked up by committees, the same being reported upon at the proper time.

COLOR BLINDNESS.

A COMMITTEE of the Legislature of Massachusetts has been formed for the purpose of ascertaining whether or not legislation was necessary in regard to the employment in responsible positions upon railroads of persons who were color-blind. Dr. Joy Jeffries, of Boston, who has given the subject much study, was called upon for an opinion. To prevent accidents from

color-blindness in persons in the employ of railroads, he proposed form instead of color for signals in the day-time, and some substitute for color at night. Of the colors he stated that red was the most intense, and green the next. With color-blind persons the intensity of the colored light was the sole guide. Any color that looks dark seems red; a brighter color seems green, and a color still brighter appears white. Test a color-blind engineer, and he will, in many cases, tell the signals at once, for if he sees a dim light he knows that means "stop;" when it is brighter he feels safe, and when it is still brighter he knows he is safe.

In the course of his testimony, Dr. Jeffries, although he himself has never tested railroad employees for achromatopsia, gives some interesting statistics bearing upon the subject, leaving us to the natural inference that the defect may be equally prevalent in our own country, and among those who drive our locomotives, and those who care for the switches.

In Switzerland 171 railroad employees out of 7,953 were found to be color-blind, and discharged from the service of the companies on that account. On the Paris and Lyons Railroad 10 per cent. were found to be color-blind. In Holland 152 railroad employees out of 2,300 were found to be color-blind. Examinations in this respect are now being made in Sweden, Norway, Italy, the Austrian navy, Bavaria, Prussia, Denmark, and France. We cannot see why such examples should not be followed in our own country, and the presence of Daltonism be made a legal disqualification for any responsible position on railways. From present indications Massachusetts will probably take the initiative in the matter.

THE ELECTRIC LIGHT IN THE COAL MINES.

DR. O'BRIEN, of Scranton, Pa., in a letter, which we publish in another column, makes a suggestion regarding the use of the electric light in the coal mines, and gives good reasons for believing that the mortality among colliers would be decreased thereby. The statistics which he gives us are certainly suggestive of some remedy. The great obstacle to the introduction of the electric light is its cost; but the end to be attained certainly justifies the means to be employed. Aside from the increased illumination which can thus be given, there is no danger of the light being blown out by explosions of powder.

RAPID ANÆSTHESIA.—Give the patient the ether-inhaler, let him hold it to his face with one hand and elevate the other. In a few minutes the arm will drop, and there will be from thirty to fifty seconds of unconsciousness, during which minor operations of surgery, reduction of dislocations, etc., can be performed. The right moment must be seized, for, if the patient returns to consciousness, full etherization will then have to be employed.—*Phil. Med. Times.*

Reports of Societies.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, Dec. 16, 1878.

DR. E. INGALS, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

DR. JOHN BARTLETT read a paper entitled

A SUGGESTION AS TO THE MANAGEMENT OF PLACENTA PREVIA.

The practice now generally in vogue consisted of two methods: 1st. The use of the tampon for the triple purpose of gaining time, arresting hemorrhage, and exciting uterine contractions, and delivering by the feet as soon as the os is sufficiently dilated. 2d. Rupturing the membranes for the double purpose of arresting bleeding and exciting contractions, tamponing with the same view as in the first plan, and awaiting the progress of the labor, unless hemorrhage should be excessive, in which case the placenta is to be separated from the os as far as the fingers may reach, and the case left further to nature. After this last step it is claimed all hemorrhage will cease.

For these methods, involving the use of the tampon and separation of the placenta from the cervix, he proposed as a substitute the following practice: perforate the presenting placenta by means of an instrument resembling the thread-shield used by seamstresses, provided with a serrated edge resting upon and extending slightly beyond the nail of the index finger. Close the opening with a finger-point until, with the other hand, a Hobbs's dilator—snaped like a truncated cone, with the base upward, and having a diameter, when dilated, as great as that of the hand—is slipped into the perforation. The dilator is then quickly expanded to the size of the perforation, to prevent escape of the liquor amnii; then by gentle hydrostatic pressure the os uteri, and with it the opening in the placenta, is dilated to the size of the hand, slight traction meanwhile upon the staff of the dilator being made to secure the pressure of the placenta against the cervix, and preventing unnecessary detachment and hemorrhage. Dilatation being complete, as shown by the register of the dilator, tension is diminished by lowering the fountain, the hand is passed up beside the dilator, which is gradually collapsed and withdrawn, the hand taking its place in the cavity of the cervix. The operator then grasps the feet and delivers at once.

He objected to the methods in vogue for several reasons: the tampon was unreliable for the arrest of hemorrhage; it would frequently dam up the blood so that the latter would cause a needless separation of the placenta. The tampon had been known to be retained so long that putrefaction of the blood had taken place, and septicemia had resulted. If the tampon is removed frequently to note the progress of dilatation, quantities of blood are lost at each removal. The use of laminaria tents for dilating the os was unsatisfactory from the difficulty in keeping them in position; and Barnes's rubber-bag dilators tended to expand in the direction of least resistance, and might easily force the placenta off from the cervix to an unnecessary degree. Puncture of the membranes was objectionable, because it involved a loss of the liquor amnii, and thereby made turning difficult—an operation often required, and required promptly.

He thought Dr. Barnes was wrong in his explanation of the period of comparative cessation of hemorrhage when the cervix was fully dilated. It was not the intermittent action of the uterus in contraction that stopped the flow, but the altered relation of the vessels to the uterine tissue. This altered relation was due to the change from a state of contraction to one of dilatation of the cervix. The stretching of the cervix compresses the vessels necessarily and arrests hemorrhage. In placenta previa hemorrhage was liable to occur until the cervix was fully dilated. To await this dilatation, even with the use of the tampon, was, he thought, attended with danger. The dilatation was delayed by the attachment of the placenta acting as an unyielding splint upon the cervix; the detachment of this splint was a step in aid of the dilatation. But it was important this detachment should be as little as possible, for the prospect of the child being born alive was lessened in proportion to the extent of the separation of the placenta before delivery.

The method of practice he had set forth embodied the principle of the tampon with certainty and efficiency. No removal of the plug during the dilating process was necessary—the register of Hobbs's dilator giving positive evidence when dilatation was complete. This dilator, used in the way suggested, would lead to only such a degree of detachment of the placenta as was indispensable; moreover, it would, by its shape and position in the cervix and the rent in the placenta, prevent, to the fullest degree possible, hemorrhage. The dilator of Dr. Hobbs having the rubber bag covered with silk, it was impossible for it to expand excessively in the direction of least resistance; it must expand equally; the form of the silk bag determined the shape of the apparatus when fully dilated, therefore there could be no treacherous tearing off of the placenta to an uncalled-for extent.

Dr. Bartlett then reviewed the objections to his method. Perforation had been to a large extent abandoned, because of difficulty in executing it, danger to the child, and danger to the umbilical vessels. He thought these objections applied to perforation by the old plan, but hardly to that suggested in his paper. The cord could hardly ever be injured, as it must ever be to one side of the centre of the os. "As it is very unlikely that the main root of a tree will be found to correspond with a cavity in the ground in which it has grown, so it is highly improbable that the main attachment of the ovum would be found to be over a cavity in its bed of implantation." He referred to the interesting analogical fact that in the ungulates, as the mare and sow, there is what anatomists call a diffuse placenta, a closed sac of umbilical vessels entirely surrounding the young, and perforation of the placenta is essential to birth.

The paper was discussed by Drs. T. D. Fitch, Paoli, Ingals, and others.

Regular Meeting, Jan. 6, 1879.

THE PRESIDENT, DR. E. INGALS, IN THE CHAIR.

BRONCHITIS.

DR. F. H. DAVIS read a brief paper on the diagnosis and treatment of bronchitis. After giving a succinct description of the different forms of bronchitis, he referred to the treatment that had been most useful in his hands. The common mixture of chloride of ammonium with morphia and tartarized antimony he regarded as the most uniformly efficient in acute cases. He had used atomized fluids to a considerable extent; solution of bromide of potassium and

paregoric were valuable, also chloride of ammonium solution. Where there was a good deal of bronchial irritation in chronic cases he had found great benefit from the use of balsamic preparations by inhalation from hot water. A good combination was that of a drachm of the oil of Scotch pine in three ounces of camphorated tincture of opium, with a little magnesia. A teaspoonful of the mixture should be added to a pint of hot water, the steam from which may be inhaled from any extemporized inhaler—a teapot or tea-kettle will do.

In chronic cases, complicated with emphysema, and where breathing was difficult, he had prescribed with good effect the exhalations into rarefied air. This measure, practised frequently and regularly, would give any such patient great comfort and amelioration of condition.

HAS THE MAMMALIAN RED BLOOD-CORPUSCLE A NUCLEUS?

DR. W. T. BELFIELD read a paper on the above subject, in which he described certain experiments he had made to settle the question. Prof. Boettcher had claimed to have discovered a nucleus in the red corpuscles by first bleaching the latter with a saturated solution of corrosive sublimate in alcohol, then immersing them for a time in alcohol, and finally staining them with carmine, the centre of many of the corpuscles showing a spot more highly stained than the rest of the mass, which was the nucleus. Dr. Stowell, of Ann Arbor, had recently confirmed Boettcher's results. Dr. Belfield had repeated the experiment of Boettcher without developing any of the more highly-stained spots, and while he could not doubt the German professor had discovered them, he questioned whether they were not the result of the action of the reagents used, and therefore an artificial product.

The corrosive sublimate and alcohol coagulate albumen, and contract the tissue of the corpuscles, as shown by the micrometer. It was quite possible that some coagulate mass of a corpuscle should become more thoroughly stained with the carmine. If, however, the corpuscle had a nucleus that would take staining material in greater degree than the body of the cell, after the whole had been bleached, this ought to follow quite as readily if the bleaching were done with other agents than the one named, and with less danger of error, if the bleaching material were free from the objection of coagulating or contracting the corpuscle. Accordingly he had used acetic acid, sulphurous acid, chlorine, and a freezing temperature (none of which caused contraction or coagulation) variously for bleaching, and both aniline and carmine for staining. He had examined, with the aid of these means, reptilian blood and the blood of three mammalian species, including human blood; he had gone over the experiments several times, and while he had invariably found the nuclei in the reptilian blood more deeply stained than the body of the cell, the mammalian blood in no instance showed any trace of anything that could possibly be regarded as a nucleus. In every instance all the red corpuscles were stained uniformly in every part.

He had exhibited his specimens, prepared in the manner described, to a number of microscopists (Mr. Atwood, and Drs. Johnson, Curtis, Lyman, and Bridge), who were asked, before being informed of the manner of preparation of the respective slides, or the kind of blood they contained, if they could discover anything in any of them that resembled a nucleus. Each pronounced positively in favor of a nu-

cleus for the blood that was reptilian, but no one had been able to see such an appearance in any of the specimens of mammalian blood.

He believed that so far a nucleus had not been demonstrated to exist in the red corpuscle of man. He combated the argument that the homology of tissue required the existence of a nucleus in the blood-corpuscles. No nuclei had been found in the enamel rods or the superficial cutaneous epithelium. The function of these parts was purely mechanical, and no nucleus was needed. The office of the red corpuscles was quite as thoroughly mechanical or chemical. The corpuscles were carriers of oxygen, a purely chemical performance, certainly not a vital one, and nuclei were unnecessary.

NEW YORK ACADEMY OF MEDICINE.

OBSTETRIC SECTION.

Stated Meeting, December 26, 1878.

DR. SALVATORE CARO, CHAIRMAN.

PENDULOUS UTERUS AT FULL TERM OF UTERO-GESTATION—COMPLETE ANTEVERSION AND ANTEFLEXION.

DR. ISAAC E. TAYLOR presented an illustration, and gave a history of an interesting case in which there was complete anteversion and anteflexion of the uterus at the full term of utero-gestation—the uterus covered with the pendulous abdominal walls, and hanging between the thighs.

The woman was 22 years of age, and multiparous. When labor began the uterus was lifted as high as possible and supported by a strap over the woman's shoulders. Labor progressed so that the head descended partly through the superior strait, where it remained for about two hours. It was then though advisable to resort to artificial delivery. The pelvis was a generally contracted one, and it was evident that the uterine forces would not be sufficient to deliver the child. The forceps were applied without difficulty, but nearly an hour was required to deliver the head of the child. It then required about a hour and a half to deliver the shoulders of the child.

Dr. Taylor had published a report of a similar case in the *Medical Times* in the year 1845.

In that instance, as in the latter, he learned the value of understanding not only the rotation of the head in the pelvis, but also of the shoulders in the superior strait. After laboring about an hour unsuccessfully he reversed the order, and instead of attempting to first deliver the posterior shoulder he applied the blunt hook upon the anterior shoulder and gradually brought it to the right side, and in the course of fifteen minutes complete rotation had been accomplished, and the woman was delivered of a living child, which weighed 11½ pounds.

In this case the uterus was more perfectly pendulous than in the first case reported, and, therefore, was unique in Dr. Taylor's experience.

THE USE OF THE OBSTETRIC FORCEPS IN GENERALLY CONTRACTED PELVES.

In such cases the method of delivery by the use of the forceps was regarded as important. Not only in such cases, but forceps delivery was applicable in those in which the child was large; for, in using the forceps we should not only take into consideration the head of the child, but also its body.

In cases of generally contracted pelvis, as soon as he found that the head did not progress at all, or only slightly so, he resorted to forceps delivery.

THE USE OF THE OBSTETRIC FORCEPS IN CASES IN WHICH THERE ARE ONLY FEEBLE UTERINE CONTRACTIONS.

With reference to the use of the forceps in cases in which there were feeble uterine contractions, Dr. Taylor reported the following case:

A woman with ample pelvis was taken in labor with her first child. The head was perfectly free in the pelvic cavity, but it did not descend. The doctor decided that it was necessary to deliver by forceps, and for one of the following reasons: the head did not descend, either because of the size of the shoulders or the body, or because of the shortness of the cord, or because of an inert uterus. Which one of those three causes for delay in descent of the head was operating could not be determined. The cervix was dilated to about the size of a half-dollar, was natural to the touch, and the membranes had been ruptured about an hour and a half. The woman was put moderately under the influence of chloroform, the forceps applied, and after the head was delivered it required about three-fourths of an hour to deliver the shoulders.

Dr. Taylor thought, that without the forceps the shoulders would not have descended sufficiently far to permit of delivery of the body of the child.

He had found that in some cases the forceps became an absolute necessity for the three reasons mentioned.

APPLICATION OF THE OBSTETRIC FORCEPS ANTERO-POSTERIORLY.

With reference to the use of forceps in this class of cases (failure of a small head to descend in an ample pelvis) he had been forcibly impressed with a remark made by Dr. Hamilton, of Falkirk, that the forceps were applied "antero-posteriorly." Dr. Taylor had no hesitation in denying that Dr. Hamilton or any one else applied the forceps antero-posteriorly, because the head entered the pelvic cavity obliquely, descended obliquely, and the forceps could be applied only obliquely, either indirectly or positively so.

Dr. Taylor did not wish to be understood as urging the use of forceps when nature was apparently per-

fectly competent to accomplish delivery of the child with safety to the mother, but that there were many cases in which the instruments could be used early and with the greatest possible advantage for the purpose of making the head adapt itself properly to the cervix.

LACERATION OF THE CERVIX, AND THE USE OF THE OBSTETRIC FORCEPS.

He had yet to see harm done to the cervix uteri by a just and proper application of the forceps, and did not hesitate to record his experience against the frequent occurrence of laceration by their use, which was so rampant in the mind of the profession.

He believed that paralysis of the cervix was frequently mistaken for laceration, the same as paralysis of the perineum was frequently mistaken for laceration when the cases were examined soon after labor was completed.

Dr. Taylor's method of examination, for laceration of the cervix, was by the use of the speculum about half an hour after delivery, believing ocular demonstration to be much more reliable than touch by the finger. The speculum had shown to him that laceration did not occur to the extent supposed when the forceps were properly applied.

In cases in which the os was dilated until it became thin like a piece of paper, and the delicate cord-like Colica's muscle could be easily felt in the edge of the cervix, it was better to introduce exceedingly thin-bladed forceps, and hold the head in proper contact with cervix, than to attempt to facilitate delivery by handling the cervix with the fingers.

CHLOROFORM AS A UTERINE STIMULANT.

In some cases in which it had seemed that the forceps were necessary in order to complete delivery, the moderate influence of chloroform had been sufficient to stimulate the uterus to action, and render the use of the instruments unnecessary. In all cases, therefore, of proposed forceps delivery, he first carefully watched the stimulating effect produced upon the uterus by mild anesthesia from chloroform, and if that proved insufficient he then proceeded to deliver with the instruments.

REMOVAL OF THE FORCEPS BEFORE DELIVERY OF THE HEAD OF THE CHILD.

The delivery of the head of the child should never be completed with the forceps. When the head had been brought down against the perineum the instruments should be removed and the delivery completed after the manner of a natural labor. In that manner he avoided producing laceration of the perineum.

NON-SUPPORT OF THE PERINEUM.

Again, he never supported the perineum, but when the head had reached the floor of the pelvis and the perineum had become well distended, with two fingers placed behind the anus between it and the coccyx, he pushed the head out *in the interval between pains*, when all the parts were at rest.

POSTERIOR PRESENTATION—OBSTETRIC FORCEPS IMPERATIVE.

Dr. Taylor also stated that in cases of posterior presentation, when the head had been brought down upon the floor of the pelvis, the forceps became imperative, and therefore it was improper to attempt to complete the delivery by means of the instruments. In such cases, if delivery was completed by the forceps, there

was very great risk that serious injury would be done to the soft parts of the mother.

Dr. CARO remarked that, since he had adopted Dr. Taylor's method of delivery by forceps, he had not seen a laceration of the perineum in his own practice. Formerly he had produced laceration of the perineum, and had noticed that the rupture occurred just at the time the head was delivered and the forceps were pressing in their largest diameter.

A case was reported as an illustration: He was called in consultation to see a primiparous woman, *æt.* 26. There was general anasarca. The physician in attendance had not tested the urine. She was taken with eclampsia. The physician unfortunately thought she would be delivered by nature, and allowed her to remain in a continued series of convulsions from nine o'clock in the evening until seven o'clock on the following morning. Dr. Caro found the woman blind, unconscious, and extremely restless. Chloroform was administered to quiet the woman, the forceps were applied, and, much to the surprise of the gentlemen who were present, were removed before the head was allowed to pass the perineum. The perineum was saved, the life of the child was saved, and the woman regained her consciousness as soon as delivery of the child and the placenta was completed.

With reference to laceration of the cervix, he admitted that a certain degree of physiological laceration occurred during labor, but he thought that none of the specialists had had any of his patients to treat for laceration of the cervix.

With reference to its prevention he believed that by the use of chloral or morphine during labor, the os could be so softened that the child would be born, in most cases, without the occurrence of such accident. If laceration did occur, he thought the after-treatment had much to do with its rapid healing. His plan, in all cases of confinement, was to permit the woman, three or four hours after delivery of the child, to get up and sit upon the chamber for the purpose of emptying out the clots lying upon the floor of the vagina. In addition, keeping the parts thoroughly cleansed by the use of disinfectant injections, was very important. If those measures were thoroughly carried out he thought they would greatly facilitate cicatrization if any laceration was present.

Dr. GRISWOLD referred to a case in which profuse hemorrhage occurred from a slightly lacerated perineum. Three veins were involved in the rupture. A ligature was applied to each of the bleeding vessels, after which the laceration was closed.

Dr. CARO referred to hot water as a measure for arresting such hemorrhage, even though as profuse as represented in Dr. Griswold's case.

Dr. GRISWOLD also referred to a case of obstinate vomiting in pregnancy, and asked for counsel with reference to treatment. The woman was a multipara, about one month advanced in pregnancy; had almost constant vomiting and almost constant diarrhoea; and, although not hysterical, had from six to twelve tonic spasms daily. The diarrhoea had interfered with rectal alimentation. She had not suffered in like manner in her former pregnancies. The spasms, occasionally, were of considerable duration—one having lasted for two hours. They were epileptiform in character. She had not suffered previously from epilepsy. She was forewarned of their occurrence by severe pain in the region of the heart, extending up to the left shoulder, down the arm, and when it reached the hand she was seized with the spasm. The anginal character of the symptoms suggested nitrite

of amyl, but it had been tried without benefit. The uterus was somewhat anteverted, and was apparently in a soft, natural condition.

Dr. TAYLOR suggested tr. iodine or tr. nux vomica, in doses of five drops; also that a pessary might be used which would support the uterus until the advance in pregnancy raised it out of the pelvis. He thought there was no special danger of producing uterine contractions by such treatment. He also suggested dilatation of the os as recommended by a physician of Manchester.

Dr. CARO suggested hypodermic injections of hydrate of chloral in ten-grain doses.

Dr. F. V. WHITE referred to a case in which delivery was retarded by a short cord. The cord was finally cut and the child was born very quickly. He believed that if the forceps had been applied in accordance with Dr. Taylor's suggestion, the woman would have been saved from a great amount of suffering.

METHOD OF PREVENTING AFTER-PAINS.

He also referred to a case seen with the late Dr. Peaslee, who said that he always remained by the bedside of the woman for at least one hour after the birth of the child; that the last thing he did before leaving her was to carefully remove all clots from the os; and that by so doing, as a rule, he prevented the occurrence of after-pains.

After the nomination of officers the Section adjourned.

SECTION IN SURGERY.

Stated Meeting, December 20, 1878.

DR. STEPHEN SMITH, CHAIRMAN.

THE PRESENT AND THE PROSPECTIVE STATE OF ELECTROLYSIS IN SURGERY.

Dr. G. M. BEARD in a concise manner presented the following points relating to the above subject:

The definition which he gave to the term electrolysis was "decomposition by means of electricity," and it was to be distinguished from the galvano-cautery when, not electricity, but the heat produced by electricity was used.

In all external applications of electricity there was liable to be more or less electrolytic action, but the term electrolysis was applied especially to applications of electricity where needles were used. Practically it was limited to that, although in a strict scientific sense there was more or less electrolytic action in very many of our electrical applications when needles were not used.

The *rationale* of the electrolytic action was complex. Three elements entered into its action:

1. The actual chemical changes which took place at the positive and the negative poles.
2. The stimulating effect upon the secreting and absorbing surfaces; and
3. The effect upon nutrition through the nerves.

Dr. Beard then spoke of the electrolytic treatment of several diseases:

First, of Nevi.—There were three varieties of nevi: 1. That raised above the skin; 2. That situated in the skin—the port-wine mark; and 3. That underneath the skin. He had obtained the best results from electrolytic treatment in the first variety, and second best in the third variety. In the first and third varieties, the results which he had obtained had usually been very satisfactory. Sometimes scars were produced, sometimes not, according to the size and the locality

of the tumor. He thought it better in these cases to have a repetition of operations with a feeble current and short applications, rather than produce scarring by the use of a strong current and long applications. Slight sloughing was not always a bad result. In some cases it was impossible to destroy the tumor without producing sloughing in a mild degree. In other cases there was no sloughing and no scar.

He had operated upon tumors of that kind on all parts of the face, in children varying in age from a few weeks up to three or four years, and was very much pleased with the average results. In some of those cases, ordinary treatment by injections of iron, by applications of collodion, and by cautery, had been unsuccessful. Full anæsthesia was used, and preferably that produced by chloroform, for two reasons:

1. Because it was the experience of the world that infants bore chloroform well; and

2. Because the electrical treatment was the best possible antidote to chloroform.

He had not seen any bad results produced by chloroform in any of these operations.

Second, of Cystics, benign and malignant, such as hydrocele, weeping sinew, etc.

The object was to excite the secreting and absorbing surfaces, and for that purpose the negative pole was preferable, and strong currents. He had known of hydrocele disappearing after a very brief application of the negative pole. In such cases there could not have been electrolysis, but the effect was due purely to the action upon the secreting surfaces.

Third, of Goitres and Exophthalmic Goitres.—Exophthalmic goitre was a nerve disease, and was usually treated by galvanism without needles. In some cases excellent results and permanent cures had been obtained.

Some varieties of goitre were perfectly cured by electrolysis. The negative pole was usually employed with the positive outside of the sponge, and without an anæsthetic.

Some of the goitres were one-half or two-thirds cured. In other cases, especially those of the fibrocystic variety, extended treatment might be required to effect a cure.

In some cases he had used injections of fluid extract of ergot or sclerotinic acid, in doses of from five to twenty drops, in conjunction with electrolysis.

Fourth, of Epithelioma.—At this point Dr. Beard gave his philosophy of cancer. There existed in the person, *first*, an hereditary tendency to cancer. That tendency was developed by some local injury, such as a blow, etc.; but when first developed it was purely a local trouble, and infected the system secondarily.

The practical deduction from the philosophy was, that while the disease was yet local before the system had become infected, the method of electrolysis of the base of the tumor was efficacious. It was used upon the same principle as was the arsenic-paste treatment.

Fifth, of Cancer of other Varieties, Scirrhus.—In the majority of cases, electricity, in the way of electrolysis or external galvanism, relieved the pains of incurable cancers. In some cases there appeared to be an arrest of growth; in other cases there was a diminution in size, and in still others there was no apparent good effect.

Sixth, of Fibroids.—Fibroids of any kind were slow to treat by electrolysis, for the simple reason of their hardness. Other conditions being the same, the harder the tumor the less it yielded to electrolysis

without reference at all to malignancy or non-malignancy. Some uterine fibroids would grow smaller or disappear under electrolysis, and in nearly all cases numbness, neuralgia, and other incidental symptoms might be relieved by electrolytic treatment. The use of large knives or needles, or large galvano-cautery batteries in the electrolysis of fibroids was unnecessary, unadvisable, and unscientific. It was not, however, the electricity in these cases, but the size of the needles, which did the harm. Small needles could be used through the abdomen in large numbers, and connected with mild currents, without doing any harm to the peritoneum.

Seventh, of Glandular Tumors.—Those yielded slowly to electrolysis. Thayer's method of strong Faradization to break up tumors mechanically, and Golding Bird's method of body batteries, he had used with a certain degree of success.

Eighth, of Ovarian Tumors.—There was no present probability that electrolysis would accomplish very much for ovarian tumors. If tumors of that kind were seen very early while small, it was not improbable that they could be cured by electrolysis, just as cystics in other parts of the body were cured, such as hydrocele, etc. But, practically, surgeons did not see those cases very early. The claim that ovariectomy could be displaced by electrolysis was not sustained by practical experience.

Dr. Beard also referred to aneurisms, ulcers, and certain diseases of the skin. The published statistics regarding the treatment of aneurisms by electrolysis were of but little value. Ulcers might be treated by body batteries.

The future of electrolysis in surgery depended upon radical advances made in electro-physics beyond what had already been done by experts in that department. Electro-therapeutics in all departments was based upon electro-physics, and all the radical advances in electro-surgery had been preceded by advances in therapeutical and practical electro-physics.

Dr. A. C. Post expressed a doubt regarding the propriety of using chloroform for producing anæsthesia when ether could be employed, and referred to a case in which death was unexpectedly caused by administering chloroform to a child eleven years of age. He also asked whether emboli might not come from the clots formed by electrolysis?

Dr. F. V. White remarked, that according to his own experience, chloroform was a much safer anæsthetic than ether, and referred to cases in which rather alarming symptoms had followed the administration of ether.

Dr. Stephen Smith referred to the general use of chloroform, and thought it was a safe anæsthetic.

Dr. De Luna referred to an aneurism by anastomosis, which Dr. Saas had treated successfully by electrolysis.

Dr. Beard, in conclusion, stated that his remarks with reference to chloroform applied only to its use among infants and children under five years of age. He never gave the chloroform himself, but always trusted it to some person whose duty it should be to devote his exclusive attention to its administration, and directed that small quantities only be used, and with every possible precaution. He always felt safer in its use because electricity, which was an antidote, was being used at the same time. With reference to the formation of emboli from the clots, he thought there was no danger in that direction, because the electrolysis excited a slight inflammation; which caused the clot to adhere to the walls of the tumor.

The Section then adjourned.

New Instruments.

AN IMPROVED HYPODERMIC SYRINGE.

By GEO. R. FOWLER, M.D.,

BROOKLYN, N. Y.

AMONG the many disadvantages attending the use of the present form of syringe may be mentioned the following:

1st. Drying of the piston, it being usually made of leather or like material, and consequent loss of time (on an occasion, perhaps, when an urgent necessity exists for its immediate use) in swelling or soaking the same.

2d. The danger of loose particles becoming detached from the leather packing and being injected along with the solution. This is a positive danger and not an imaginary one. I have no doubt that many cases of abscess following hypodermic injections are due to this cause and not to the presence in the solution of undissolved crystals of sulphate of morphia, as generally supposed.

3d. The leather packing requires to be frequently oiled and this soon converts the piston into a greasy mass besmearing the interior of the barrel.

4th. Wearing out of the case. The cases are made of wood covered with leather, and in warm weather especially the glue which cements the leather to the wood softens, and the case is soon destroyed and useless.

The syringe here described consists of a barrel, needle, A, piston, B, and receptacle, C, for powders. The barrel is made of hard rubber, and to one extremity is attached the needle in such a manner as to be easily unscrewed and removed. The piston is also made of hard rubber, and is accurately fitted to the barrel. The receptacle contains in its interior a guard or cover to protect the needle from injury when the whole is screwed together. This receptacle has a cap, D, the removal of which discloses a compartment for the reception of either solution or powders, preferably the latter. Into this compartment eight powders of a quarter of a grain each of the sulphate of morphia can be placed. The whole instrument when screwed together as at E, is about the size and shape of an ordinary hard-rubber thermometer case, and occupies no more room in the pocket.

My usual plan, when about to give a hypodermic injection, is to remove the receptacle, unscrew the needle, draw back the piston and empty one of the powders into the barrel. I then pour a few drops of water into the barrel, replace the point, and after giving the instrument a few shakes to make sure that all of the sulphate of morphia is dissolved, the instrument is ready for use.

This syringe may be made available for carrying in the pocket-case by having a simple guard screwed over the needle instead of the receptacle.

The advantages claimed for this instrument are:

- 1st. Accuracy of dosage.
- 2d. Simplicity in construction, there being no complicated parts to get out of order.
- 3d. Durability; the entire syringe, except the point, being made of hard rubber.
- 4th. Cleanliness, no oil or other lubricant being present to soil the interior.
- 5th. Always ready for use, the piston being made of solid hard rubber, and never requiring to be soaked before using.
- 6th. Its portability, being of very small size.
- 7th. Cheapness, being sold for less than the common syringes.

Correspondence.

SHAKSPERE ON THE PRACTICE OF MEDICINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The many-sidedness of Shakspeare's mind is, to physicians, interestingly evidenced in the several occasions whereupon he refers, directly or indirectly, to matters pertaining to physic; or where the isolation or accentuation of certain passages make him appear to so refer. In illustration of this point I have selected the following excerpts from several of the plays:

OBSTETRICS.—“*Mar.* Does it work upon him?
“*Sir Toby.* Like aqua vitæ with a midwife.”—*Twelfth Night.*

HEPATIC THERAPEUTICS.—“ — brimstone in your liver.”—*Ibid.*

CATHARTICS.—“ — grown sick of rest, would purge.”—*Ant. and Cleop.*

SYPHILIS.—“ Pox on't!”—*Twelfth Night.*
CLINICAL EXAMINATION OF URINE.—“*Fal.* Sirrah, you giant, what says the doctor to my water?”

Page. He said, sir, the water itself was a good, healthy water; but for the party that owed it he might have more diseases than he knew for.”—*K.*

Hen. IV., Part 2.

SPLENITIS.—“ You shall digest the venom of your spleen.”—*Jul. Cæsar.*

GENERAL SURGERY.—“ — hurt him in eleven places.”—*Twelfth Night.*

BRACHIAL PARALYSIS.—“ I cannot scratch my ear.”—*Ant. and Cleop.*

VENESECTION.—“ Nay, then, I must have an ounce or two of this malapert blood from you.”—*Twelfth Night.*

ALCOHOLISMUS.—“ O he's drunk, Sir Toby, an hour agone.”—*Ibid.*

SURGERY.—“ For the love of God, a surgeon.”—*Ibid.*

A GENERAL PRACTITIONER CONFRONTED WITH A SPECIALIST'S PROBLEM.—“ This disease is beyond my practice.”—*Macbeth.*

FRAGILITAS OSSUM.—“ The dryness of his bones.”—*Ant. and Cleop.*

EMBOLUS.—“ This does make some obstruction in the blood.”—*Twelfth Night.*

A PHYSICIAN DEFINED.—“ Master doctor, he is a curer of souls, and you a curer of bodies.”—*Merr. Wives.*

ASTHMA.—“ — pants, and looks pale.”—*Twelfth Night.*

PRESCRIPTION.—“No dram of a scruple; no scruple of a scruple.”—*Ibid.*

NECROPSY.—“Then let them anatomize.”—*K. Lear.*

CHLOROSIS.—“— and Lepidus, as Menas says, is troubled with the green sickness.”—*Ant. and Cleop.*

CIRRHOSIS OF LIVER.—“— let there be gall enough.”—*Twelfth Night.*

SURGERY.—“Honour hath no skill in surgery, then.”—*K. Hen. IV., Part 1.*

LEUCOCYTHEMIA CURED.—“— will turn to redder drops.”—*Jul. Cæsar.*

UTERINE TUMOR.—“— which from the womb.”—*Twelfth Night.*

CASTRATION.—“Thou eunuch!”—*Ant. and Cleop.*

HEPATIC CONGESTION.—“I had rather heat my liver with drinking.”—*Twelfth Night.*

REGIONAL SURGERY.—“I'll fetch some flax and whites of eggs to apply to his bleeding face.”—*K. Lear.*

MANIA.—“Do not think I am mad.”—*Twelfth Night.*

COPIOSIS.—“Fal. Boy, tell him I am deaf.”—*K. Hen. IV., Part 2.*

MEDICAL CONSULTATION.—“What says my Esculapius, my Galen?”—*Merry Wives.*

CORYZA.—“He was troubled with a rheum.”—*Ant. and Cleop.*

SUPPOSITORIES.—“— when remedies are past.”—*Othello.*

JAUNDICE.—“— hath with his tinct gilded thee.”—*Ant. and Cleop.*

LEPROA.—“— whom leprosy o'ertake.”—*Ibid.*

MINERAL WATERS.—“Nay, I am for all waters.”—*Twelfth Night.*

BENEDICTION ON AN “M.D.”—“Bless thee, bully doctor!”—*Merry Wives.*

These examples (which might easily be multiplied) serve to show that if the mighty master possessed no technical knowledge of our art, he was, at least, observant of it, and often referred to it.

Very respectfully yours,

F. BRADNACK, M.D.,

No. 70 EAST EIGHTY-SIXTH STREET, N. Y. CITY, Jan., 1879.

[A few more occur to us.—ED.]

FLATULENCE.—“The winds grow high, so do your stomachs, lords.”—*King Henry VI., Act II.*

PROBABLY GANGLIONIC DEGENERATION OF THE ANTERIOR HORNS OF SPINAL-CORD.—“Alas! master, what shall I do? I am not able to stand.”—*Ibid.*

THE ANTISEPTIC METHOD.—“The foul and ugly mists of vapors that did seem to strangle him.”—*King Henry IV., Act I.*

TWENTY PER CENT. CARBOLIC.—“I smell it; upon my life, it will do well.”—*Ibid.*

SURGERY IN THE COAL REGIONS.

TO THE EDITOR OF THE MEDICAL RECORD,

DEAR SIR:—In compliance with your courteous request for statistics of accidents and peculiarities of surgery in the Anthracite region, I send you the following hastily penned items, inviting your attention specially to the suggestion of *light* as the remedy of the future for the appalling dangers of the mines.

From 1871 to 1877 (inclusive) there were killed in the Anthracite mines of this State 1,682 men, and injured 4,171, leaving 968 widows and 2,804 orphans. Bituminous mining is comparatively safe. The Anthracite region is divided into five districts; the reports of the Inspectors for 1878 are not yet made up, but through the courtesy of Mr. W. S. Jones, Inspector for the Lackawanna region, I have secured the following

figures: killed in this district in 1878, 33; injured, 189. 75 per cent. of these accidents in 1878 were caused by “fall of roof.” No accident occurred from explosion of gas. Mr. Jones informs me that this good result follows from better ventilation, and the exclusion of the safety lamp; he has forbidden the latter in his district on account of the small margin of safety it furnishes, and the neglect of better precautions which it has been made to excuse.

I thought I had seen the possible dangers of mining exhausted in falls of roof, explosion of carburetted hydrogen, and explosion of powder; suffocation by carbonic acid gas, and suffocation per se; accidents by caves, fire, and cars, etc., but last summer witnessed another element added to the list. In the floods of August 31st, Pine Brook burst into the Fair Lawn Slope; the men cut their way into the Pine Brook Mine and escaped by the mule-way, all but one; a miner caught two boys and faced the torrent of water coming down the slope breast high, bearing ties, coal, and débris, and lifting the car-track from its bed; on this he stumbled, struggled upward, and escaped with one boy.

Furnaces have given way to fans in nearly all the mines of this region; a vast improvement for ventilation. The law requiring a second opening into all mines is well observed since “Avondale” and “West Pittston,” yet this terrific mortality from “fall of roof” remains. All hands attribute it to carelessness, but I have long been convinced, from personal observation underground, that the great remedy needed is LIGHT. I hope to see the day when the miners can work in their chambers with every crack and flaw in the roof overhead blazing in electric light.

The preponderance of the form of accident mentioned gives us many and unique cases of injury of the head, back, and spinal column.

February 12, 1877, P. McG. was struck on the back by fall of roof, which at the same time killed his helper; next morning I cut from the urethra of McG. a renal calculus, conical and truncated, measuring three-eighths by one-half of an inch; he had been previously under my observation for dysentery; the absence of vesical symptoms, the shape of the stone, and the finding of it immediately after the terrible blow on the back, make it certain to my mind that it was from the kidney. If I am right, the accident which killed his partner *cured* him; and an old suggestion for the dislodgment of renal calculi is affirmed.

Concussion of the spinal cord from fall of roof is so common that we become familiar with all varieties of paraplegia; it is an interesting study, responding with remarkable accuracy to careful prognosis; although the prime factors are first, seat, and second, extent of the injury to the cord, and they are not usually open for inspection, yet the nervous manifestations indicate them as the deflections of a galvanometer locate a fault in the electric circuit. Does complete paralysis extend to the umbilicus?—then death is almost certain. Does it only approach the hips?—then recovery is quite probable. In the zone between these points the anæsthetic index often wavers between life and death. I have seen cases of paralysis of the bladder (and lower extremities) requiring the constant use of the catheter for weeks, in which a little area of hyperæsthesia round the hips prompted a favorable prognosis, which the result always justified.

We have small hospitals here and at Wilkesbarre; the following are the statistics for 1878 here: In-patients, 89; out-patients, 1,194; amputations, 7. Double and triple amputations are common, and when simultaneous show a fair percentage of recoveries.

Consecutive amputations cannot be too severely condemned.

Dislocations of the hip, with all manner of fractures, are common; good surgeons hereabout make a rule to reduce all such dislocations, for obvious reasons, unless the patient is already dead.

The coal region maintains a small army of cripples as a monument to bad surgery; femurs treated without extension, and shortened from three to five inches; badly treated fractures of the clavicle, mistaken for acromial dislocations; unrecognized dislocations of the hip, and badly treated and ankylosed joints of all the limbs, are some of the records of quackery in the past.

This valley (the Lackawanna) and the Moosic Mountains round about, are entirely free from malaria; patients from ague districts suffering from not incurable lung affections, do well here.

Sincerely yours,

J. E. O'BRIEN.

SCRANTON, PA., Jan. 20, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 19 to January 25, 1879.

IRWIN, B. J. D., Major and Surgeon. Par. 7, S. O. 176, A. G. O., Aug. 15, 1878, granting him one year's leave of absence, is amended to grant said leave on surgeon's certificate of disability. S. O. 16, A. G. O., January 20, 1879.

LORING, L. Y., Capt. and Asst. Surgeon. Relieved from duty at Fort Hays, Kans., to proceed with Co. B., 23d Inf., to Fort Dodge, Kans., and there report to Col. Jeff. C. Davis, 23d Inf., for duty, to accompany the troops of his command and take post with them. S. O. 12, Dept. of the Missouri, January 20, 1879.

WILCOX, T. E., 1st Lieut. and Asst. Surgeon. Granted leave of absence for four months. S. O. 16, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Comparative statement of cases of Contagious Diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending January 25, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Jan. 18, 1879.	0	9	204	5	6	52	0	0
Jan. 25, 1879.	0	4	216	1	2	54	0	0

THE MARY FLETCHER HOSPITAL IN BURLINGTON, VT.—The formal opening of this beneficent institution took place, with appropriate ceremonies, in the city of Burlington, Vt., on Wednesday, January 22, 1879. This hospital was built and endowed by the munificence of Miss Mary Fletcher, and appropriately bears her name. The principal address was delivered by Prof. D. B. St. John Roosa, of this city, and was in

every respect a worthy production. Brief addresses were also delivered by Prof. Walter Carpenter, President of the Board of Trustees, and by President Buckham, of the University, who is also one of the Board of Directors. The amount donated for the noble purpose was \$175,000.

THE NEW DEAN OF JEFFERSON MEDICAL COLLEGE.—Elliesslie Wallace, M.D., Professor of Obstetrics, has been elected Dean of the College in the place of J. B. Biddle, M.D., deceased. No new professor of Materia Medica will be elected at present, as Robert E. Rogers, M.D., Professor of Chemistry, will deliver the lectures in this branch until the end of the present term.

VALEDICTORY ADDRESS AT THE PHILADELPHIA SCHOOL OF ANATOMY.—The lecture-room of the Philadelphia School of Anatomy was crowded on Friday evening, Jan. 10th, with medical men and students to listen to the closing lecture by Dr. John V. Shoemaker, in the department of diseases of the skin. The speaker pointed out the scientific manner in which the class had been educated so as to be "masters of all exclusive systems of medicine;" that they had frequently witnessed in the clinics the good result of the use of medicine, in both large and small doses, and the applications of electricity and of water for the cure of disease. It was shown that each remedy could not supersede, but must co-operate with others, and their selection must be guided with appropriate knowledge, sound judgment and accomplished skill. They were, therefore, scientific physicians, and not allopaths. The name "allopaths," he contended, was a misapplication, was not their proper title, and was invented by Hahnemann, to designate the ordinary practice of medicine as opposed to homœopathy. In conclusion, the speaker appealed to the physicians and students present to assist in eradicating the popular delusion in the misuse of this name of "allopath," and advised them in all cases to follow the instructions they had received, by using anything whatever that can be found to save life, relieve pain, and preserve health.

THE NEW LABORATORY BUILDING OF THE UNIVERSITY OF PENNSYLVANIA MEDICAL SCHOOL.—The work on this building was begun in May, 1878, and by November last the first, second, and third stories were ready for occupancy. The fourth floor is not to be finished until next fall. The structure is 152 feet long, by 47 feet wide; is four stories in height—68 feet—with Mansard roof, and is built of gneiss and serpentine stone. Each story is lighted by thirty-eight windows. The first floor is arranged for dental clinics, having thirty-four of the most approved style of operating-chairs, etc. The manipulating rooms of the chemical laboratory on the second and third floors are without partition in their whole extent. The students have in common the use of seven balances and two microscopes. Both floors have sixteen fully equipped fume-closets, and also two double rows of working-tables. Each student occupies a separate working-table fitted with gas, water, sink, etc. When night-work is necessary, sixty-two gas-burners give the necessary light.

The course of study pursued by the students of the first year in practical chemistry is entirely analytical, occupying eight hours each week. The work of the first year consists, first, in testing for the reactions of all but the very rare metals, and, second, in making out the equations for these reactions. At the end of this course there is an examination, which, successfully

passed, the student begins the analysis of unknown substances. Thus far the course is compulsory. Those who have done well are then allowed to take up quantitative analysis.

The second year's work in the laboratory requires four hours each week. It consists in analyzing and separating all the organic acids used in medicine, and a qualitative, quantitative, volumetric, and gravimetric examination of urine for its various normal and abnormal ingredients. The remainder of the year is spent in toxicological investigations. Poisoned animals are allotted to the students for examination. The mode of administration of the poison and its effects upon the various organs are carefully studied out.

The fourth floor, when completed, will be occupied by the physiological, pathological, and histological laboratories. There will also be a room for experimental therapeutics. The building is heated by hot-air furnaces. A fire-proof stairway in a projection on the north side of the building connects all the stories. The ceilings of all the rooms are lined with plate-iron, and supported by wrought-iron pillars. The entire cost, exclusive of apparatus, has been about \$55,000.

TRI-STATE MEDICAL SOCIETY.—The Tri-State Medical Society of Illinois, Indiana, and Kentucky began its annual session at Springfield, Ill., Nov. 13, 1878. A three days' session was held, during which many papers were presented. The subjects of modern lithotomy, of education, and of the yellow fever were especially discussed. The following officers were elected for the ensuing year: President, Dr. J. H. Ireland, of Louisville; Vice-Presidents, Drs. Compton, Griffith, and Holloway; Secretary, Dr. G. W. Burton, of Mitchell, Ind.; Treasurer, Dr. F. W. Beard.

MR. A. PRETTERRE, surgeon-dentist, of Paris, obtained at the Universal Exhibition of Paris the sole gold medal awarded to dentists.

A NEW UTERINE SOUND.—Codman & Shurtleff have recently devised a very ingenious sound, which is likely to facilitate the exploration of the uterine canal, and the diagnosis of displacements, new growths, etc. It consists of a bundle of light steel springs fifteen inches long, united at the ends, and placed within a small spiral wire which surrounds them with the exception of three inches at each extremity. Between the first and second fourth of its length is placed a handle, the rest of the sound is covered with a flexible rubber sheath. The longer portion is introduced into the os, and then, by gently manipulating the external end, the internal end can be moved in any direction. When the instrument is fairly introduced, the shorter external fourth has a curve exactly corresponding with that which is given by the uterus to the part within its cavity.

INTROLIPTIC MEDICATION.—Prof. L. P. Yandell urges the more extensive use of introliptic medication, that is, the rubbing into the skin of drugs and nutritious oils. He has had satisfactory results from quinia by mixing it with glycerine, $\zeta j.$ to $\xi j.$, and rubbing in a sixth or a fourth of this daily. He has cured diarrhœa by rubbing tannic acid and glycerine into the abdomen, and has seen diarrhœa result from the inunction of croton oil. He has great faith in the inunction of cod-liver oil, olive oil, or hog's lard in phthisis and marasmic conditions.—*Louisville Med. News.*

IN MEMORIAM.—It is noticeable that nearly all the medical societies in the South and West have adopted resolutions, or published addresses in memory of the physicians who died at their post during the recent yellow fever scourge. Many of these memorial proceedings have been published in all the newspapers of the infected localities.

INTRAVENOUS INJECTION OF MILK.—At a recent meeting of the Philadelphia County Medical Society, a paper was read on this subject, by Dr. Wm. Pepper. He concludes, among other things, that there is no danger from embolism, that its first effect is stimulating, that its subsequent effects are less lasting than those of transfusion, and its subsequent symptoms may be as severe. It may hasten death in structural anæmia.—*West. Med. and Surg. Journal.*

BODY-SNATCHING.—The editor of *The Nashville Journal of Med. and Surg.* seconds very forcibly the demand which is springing up for better laws in regard to dissection and the supply of material. He justly attacks the stupidity and short-sightedness which make it a penitentiary crime in some States to dissect a human body. Body-snatching will exist until there are laws which arrange for the proper supply of material for medical colleges.

DEODORIZED IODOFORM.—The disagreeable odor of iodoform limits its usefulness very much. It is said that this odor is covered in a solution made as follows: Tincture of iodine is shaken up with a fragment of fused potash until the color is removed. The odor of the iodoform thus produced is concealed by adding eau de Cologne. Iodoform mixed with tannin is also said to be nearly without smell.

THE YELLOW FEVER GERM, it is calculated, travels at the rate of 40 feet in 24 hours.

CARBOLIC ACID SPRAY IN PHTHISIS has been tried at Mt. Sinai Hospital, in this city, and found to increase the amount of expectoration, stop fetor, and reduce the temperature.—*Hospital Gazette.*

THE WARM-WATER TREATMENT.—Dr. A. H. Goelet reports to the *Hospital Gazette* a case of the successful treatment of phlegmasia dolens by wrapping the limb in flannel, saturating this with warm water, and covering it with oiled silk. The ordinary treatment was tried first, and abandoned.

SALIVA AND THE DIGESTION OF STARCH.—Dr. R. M. Smith, in a lecture on experimental physiology, at the University of Pennsylvania, showed that the gastric juice only suspended the action of saliva in changing starch to sugar, the action being resumed when the acidity is neutralized by the intestinal juices. He showed also that while caustic alkalis destroy the catalytic action of saliva, the weaker alkalis only suspend it. This proves the rationality of giving these alkalis in acidity of the stomach or mouth. It gives a better chance for the digestion of amylaceous foods.—*Med. and Surg. Reporter.*

THE DRY SUTURE.—Dr. John H. Packard recommends this in closing long wounds. He uses strips of Seabury & Johnson's porous plaster two and a half inches wide and the length of the wound. These are applied on each side of the incision, and then the sides laced together, using the holes in the porous plaster.—*Phil. Med. Times.*

RESOLUTIONS ON THE DEATH OF DR. BIDDLE.—At a meeting of the Faculty of Jefferson Medical College,

held on Jan. 20th, the death of Dr. John B. Biddle, Professor of Therapeutics and Materia Medica, and Dean of the Faculty, was announced; whereupon the following was ordered to be entered upon the minutes of the Faculty:

"The Faculty of Jefferson Medical College find themselves plunged into the deepest sorrow by the death of their fellow-member, Dr. John B. Biddle, Professor of Therapeutics and Materia Medica, and Dean of their body, which occurred on the evening of the 19th inst. As a friend, they feel sadly the void thus created, and mourn over the departure of a greatly-loved companion. Endeared to them by his noble qualities of head and heart; as their colleague and executive officer, they realize the irreparable loss of a sound and sagacious thinker, an able and successful teacher, and a faithful, experienced, and judicious executive, whose untiring zeal and earnest labors in his own department, and for the school at large, have contributed so much to maintain the usefulness and advance the reputation of Jefferson Medical College.

"The Faculty feel that words are inadequate to express their sense of this bereavement, but desire to make record of the estimate in which they held the deceased, whose memory they will ever cherish with sincerest affection.

"They desire to convey to his sorrow-stricken family their warmest sympathy, trusting that in the knowledge they have of the esteem in which he was held in the community, and the love which was borne him by all his co-laborers and friends, and that he has left them in the assurance of a Christian faith for that larger life which is eternal, they may find comfort and consolation.

"Resolved, That a copy of this testimonial of the Faculty be transmitted to the family of Dr. Biddle, and also to the honorable Board of Trustees; and that the Faculty will attend his funeral in a body."

ELLERSLIE WALLACE, *Dean.*

THE NEW LECTURESHIP IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA.—The Medical Faculty of the University, at their meeting on Jan. 20th elected Dr. Charles B. Naucrede lecturer on "The Anatomy of the Bones and Joints," in the spring course. The other candidates were Drs. Rush, Shippen, Hindekoper, Henry Wharton, Charles W. Dalles, and Hollingsworth Neill. Through an error, in a recent number of the RECORD, we spoke of the position for which Dr. Naucrede was a candidate as "a new chair of the Anatomy and Surgery of the Joints."

A VETERINARY DEPARTMENT IN THE MEDICAL SCHOOL OF THE UNIVERSITY OF PENNSYLVANIA.—It may be of interest to the general profession to know that about ten months since the question was put to the Faculty of the Medical School of the University of Pennsylvania as to whether they would create and take charge of a Veterinary Department upon the condition that, as a first step, an endowment fund of \$50,000 were raised and presented to them. The Faculty referred the matter to the Trustees of the University, who voted to answer affirmatively and accept the proposition. Ever since that time the gentleman who made the offer, Mr. Horace Smith, has been engaged in collecting the stated sum, but he has thus far made no statement of progress made.

AVOIDANCE OF PAIN AFTER AMPUTATION.—REMARKS BY MR. CALLENDER, OF LONDON.—At a clinic held in Bellevue Hospital, January 26, 1879, Mr. Callender, on invitation by Prof. James R. Wood, amputated a

thigh and made a few practical remarks with reference to preventing pain after such an operation.

There were many ways in which a surgeon might achieve success, but he wished to make mention of that specially characterized by a most careful observance of details and great personal care and attention to the case.

He thought surgery had so far advanced it could safely be said that, in a well-organized hospital, and with a skilful surgeon, the death-rate need not exceed six or seven per cent. He also believed the time was not far distant when even that rate of mortality would be reduced. Such results were, in a great measure, to be achieved by a careful consideration of everything which tended to give the patient pain and discomfort.

After the limb had been amputated, and the patient had been removed to the ward, there was a certain amount of distress and discomfort produced by the anæsthetic. Such was usually dealt with most satisfactorily by the administration of a sedative. He therefore made it an invariable rule to see that a sedative was administered immediately after the patient had fairly returned to consciousness. It was a small point, but it was worthy of recollection. How was the sedative to be given? Never by the stomach, but always by subcutaneous injection. The pain which the patient might suffer could be considered under two distinct heads:

1. That produced by external causes; and
2. That dependent upon internal causes.

The pain produced from causes without might be more or less referred to the position of the limb, movements of the body, changing the position of the limb, and very commonly it came from the handling by the surgeon. He recollected the time when the stump of an amputated limb was laid upon the bed, and when it was necessary to change the dressing, the surgeon was obliged to place his hand beneath it and lift it up, a proceeding which involved considerable disturbance of the parts and consequent pain to the patient; so much so, that he would almost always cry out on account of it.

To avoid such disturbance, reference was made to an apparatus which was to be applied to the amputated thigh, and briefly described on a former occasion.

With reference to the disturbances which come from *within*, there was what was called "*jumping of the limb.*" As the patient falls asleep, perhaps, there was a jerking of the muscles, which awakened him, and caused him to cry out with pain. To prevent such jumping, he always made it a point to stretch the important nerves in the limb, simply for the purpose of numbing them.

Another trouble which came from within, and gave rise to pain and discomfort, was *distention of the stump with fluid, which necessarily separated the surfaces, rendering the patient liable to blood-poisoning, and prevented union by first intention.*

That could be entirely avoided by the use of a drainage-tube. The drainage-tube was prepared in the following manner: a piece of india-rubber tubing, long enough to pass completely across the limb, was cut in the middle and then united by means of a piece of ordinary catgut ligature. The catgut would be absorbed in about sixty hours, and then the pieces of drainage-tube could be removed from each side of the limb. Removed in that manner, the patient suffered very much less pain than if the whole tube was drawn through the stump. The amputation was then performed, and a description given of the apparatus (*vid. MED. RECORD, Jan. 11, 1879, p. 26.*)

Original Lectures.

PRACTICAL HINTS UPON TRACHEOTOMY.

BEING THE ABSTRACT OF A CLINICAL LECTURE DELIVERED AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE,

By BEVERLEY ROBINSON, M.D.,

LECTURER UPON CLINICAL MEDICINE.

GENTLEMEN:—I esteem it a somewhat rare privilege and opportunity to be able to bring before you two patients, both wearing tracheal canula for more than a year. The first of these men was operated upon by me in the month of December, 1877, and was at that time suffering from recurrent attacks of paroxysmal dyspnea due to spasm of the glottis. What the efficient cause of this glottic spasm was, has as yet remained undetermined. There has been, however, a suspicion that aortic aneurism, originating in the posterior portion of the arch and irritating the recurrent laryngeal by compression, is present. No phenomena other than the repeated glottic spasm have ever shown themselves corroborative of this view, and to-day my patient tells me that for the past six months he has had at no time any notable distress of breathing, and in fact feels on the whole very well. The main, practical question in his case now is, when will it be wise to relieve him of his tracheotomy tube and close up the wound of the neck. My own belief is, the sooner it is done the better. For be it fully appreciated that although he has worn his tube lately with but slight inconvenience, it is an ever-present source of possible danger. There is danger from local irritation, ulceration, and the cropping out of fleshy granulations; there is danger likewise from attacks of cold, which might more readily lead to broncho-pneumonia, lung collapse, or even acute pleurisy during the period he wears his tube. He cannot always be on his guard against inspired draughts of cold, damp air; and obviously, unless he keeps his tube constantly closed and breathes through his nose, his pulmonary capillary circulation is ever exposed to the evil results of rapid and excessive chilling.

With these remarks permit me to pass on to the subject of to-day's lecture. As I proceed I may have occasion to refer to my patient to illustrate some of my remarks.

Tracheotomy is an operation it behooves you one and all to become familiar with, even in its minute details. In your professional career you may at any moment be called upon to perform it, and the urgency may be such that no delay would be permissible. Now, this does not hold good of very many operations. The majority of these may be put off to some convenient season, or, if it be a major operation like resection at the hip-joint, or lithotomy, may be passed over to some specially competent man to cope with. In fact, gentlemen, although some amongst you, whilst being general practitioners, may also become good surgeons, opportunity will not in all, or even many instances, be afforded you to be expert in certain operations.

It seems apropos in this place to mention the great advantages to be derived from the skilled use of the laryngoscope in many cases in which tracheotomy is indicated. How frequently are we able thus to determine the exact nature of the affection which occa-

sions obstruction in breathing. It may be, for example, that an intra-laryngeal growth exists. By means of the laryngoscope its size, seat and nature can frequently be accurately observed. A foreign body may be lodged within or below the larynx. How far it places life in imminent danger, what the best instrument and operation for its removal are, can only be known after a preliminary diagnosis with the small mirror. In many syphilitic affections of the air-passages; in pressure upon the trachea or pneumogastriacs from tumors of the neck or mediastinum; in laryngeal phthisis, after scalds and burns, subsequent to suicidal attempts; in exceptional forms of simple chronic laryngitis, and in many other conditions besides, the laryngoscope is an invaluable aid to accurate diagnosis and wise, skilful treatment.

One of the very first questions which it is wise to answer is, whether or not an inhaled anesthetic should be employed, and if so, which one it should be. My attention has been directed to this subject several times, but never more earnestly than a few months since, after assisting a friend of mine in a case where ether by inhalation had been used and where death unfortunately took place upon the table. It is true the operation was an unusually difficult one, for a large cancerous mass lay in front of and around the trachea, and this organ was greatly deviated from its normal position. Add to this very intense dyspnea of the patient at the time the operation was undertaken, and considerable hemorrhage after incision into the air-passages was of necessity made, and you perceive at once an imminently hazardous situation. I have thought that the condition of things was rendered graver still by the use of an anesthetic. And the reason is apparent, viz., the patient was unable to throw off the blood which forced itself into the air-passages, and thus an already perilous situation became rapidly fatal. Without the anesthetic influence the patient's respiratory mucous lining would probably have still retained sufficient reflex irritability to occasion cough and thus expel the indrawn fluid. In reality, once the skin has been incised, tracheotomy is not extremely painful; and moreover, localized refrigeration by means of a spray-producer charged with ether or rhigolene is all-sufficient.

In membranous croup at an advanced stage the asphyxia is so great that little or no pain is occasioned, even by the first incision. In order that the little patient may not, however, grasp the hand of the operator, or otherwise interfere with his endeavor, it is advisable to wrap the arms and trunk tightly with a sheet, or large towel of suitable length. For this and many other good practical suggestions I would refer you to Mr. Pugin Thornton's excellent monograph on Tracheotomy, published in London two years ago. There are a few points in reference to the anatomy of the trachea that it will be well always to bear in mind. The trachea is sometimes quite superficial; again it is deeply situated. This latter condition, which occurs with persons who are short and thick-set, or very fat, increases the difficulty of the operation considerably. And in this place I may add that you should always have one or two tracheotomy tubes with you of different lengths—so that you can feel sure that one at least can be introduced into the trachea when opened.

Be on your guard for anomalous arterial branches, such as the thyroidean and crico-thyroid artery, which in my experience have not shown themselves. The isthmus of the thyroid, you know, is at different heights and is of varying size. Your manner of procedure may be properly influenced by these facts.

Up to the age of two years expect that the thymus gland may be in your road. Do not lose sight of the facts that the thyroid plexus of veins are often much enlarged, and that the innominate and right carotid arteries do occasionally cross the trachea at a higher level than usual. The only essential instruments in performing tracheotomy are a scalpel and a tracheotomy tube; the others are all accessory, but are useful to have and to employ.

Amongst these I will mention particularly a faradic battery for restoring suspended animation, a pair of blunt retractors, a tenaculum, a piece of sheet spunk, and a syringe with a graduated nozzle. In performing the operation it is more convenient to stand on the right side of the patient, and if it be day-time, let the light come from a window in front. The primary incision should be quite long—say from one and a half to two inches, and as nearly as possible on the median line. This may be marked with a pencil. After the first incision is well made, let nearly all the ulterior dissection be carried on with the handle of a scalpel, or better still, Hamilton's dry dissectors. The thyroid plexus of veins, if they cannot be pushed aside, should be torn through. And in like manner the isthmus is to be treated. Some authors have feared hemorrhage from the isthmus, and have counselled passing a double ligature underneath and dividing between. This I believe unnecessary, unless the blade of the knife be used, in which case it certainly is more prudent. Let it be a cardinal rule, which is to be observed as far as practicable, that the trachea is never to be opened unless the hemorrhage be first arrested. When it is ready to open, and particularly with small children, fix the larynx and trachea by means of a tenaculum, and, after drawing it forward with a slight degree of force, puncture it with the bistoury and incise its walls from below upward. If there be subsequent hemorrhage, pass a piece of spunk under the shield of the tracheotomy tube and compress on either side of the tracheal wound. In rare instances we shall be compelled to withdraw the canula and introduce one of larger calibre. If the incision has been a long one—and it is better to err in this way than in an opposite direction—place a few points of suture and cover them with a square piece of sheet lint greased on the applied side, and partially bisected so as to pass one portion under either side of the shield of the canula. The application of the lint avoids the irritating effects from the constant contact of sputa. Before speaking of the after-treatment, I would like to say a few words in regard to the proper canula to employ.

The old-fashioned canula, curved like the segment of a circle, has the serious disadvantage of tilting upward and backward by its inner extremity, and thus causing ulceration of, and sometimes serious hemorrhage from the trachea. This may be obviated by a Durham's tube, which shows at its bend a right angle, and not the ordinary circular curve. Unfortunately the inner canula of the Durham tube is segmented, and one of these segments has been known to become detached and fall into the trachea. Such an accident might of course be fatal. By constant care and repeated examination of the condition of the inner tube, it might be worn for a long while with almost absolute safety. Besides, after a time it is not necessary to wear an inner tube at all, and in many instances even the outer tube is merely intended to be worn temporarily. The great objections to the hard rubber tubes are: 1. They corrode more or less rapidly. 2. They may and have become detached and

lodged in one of the primary bronchi. 3. They do not allow a sufficient column of air to pass in proportion with their outside diameter.

FIG. 1.

As regards the ulterior care of the patient, it is well, and indeed necessary, to have a constant attendant during the first two days, whose business it is to watch the breathing and cleanse the inner tube from time to time by means of a chicken feather. If the inner tube become very much choked up, it should be removed and thoroughly washed in water containing a small quantity of some alkali. When reintroduced it should be done with gentleness, so as *not* to cause unnecessary cough and irritation. Steam, from a croup-kettle or other convenient source, and in moderate quantity, may be permitted in the room when the mucus or other discharge from the trachea and bronchi is viscid and tenacious. On theoretical grounds, however, I am opposed to its immoderate use, as is so frequently done, because I believe it will increase the difficulty of breathing it is intended to ameliorate.

When a tube is worn permanently, it is preferable to introduce a cork in the outer orifice rather than to wear any kind of valvular contrivance, which either causes annoyance by its ceaseless noise, or quickly gets out of working order, and is then worse than useless.

When a temporary tube is withdrawn for the first time it should always be done with a considerable degree of precaution, and if it is left out too long it will be often difficult to reintroduce it. The wiser plan to follow is never to take out a temporary tube, unless it is essential so to do, so long as there is good reason to believe that the wound will not remain patulous at least for several minutes. In cases in which patients have been operated upon for membranous laryngitis, this condition usually requires four or five days to be reached. Whenever the patient goes out, or into a cooler or damp atmosphere, a light scarf should be worn in front of the tracheotomy tube, so as to ward off the risk of catching cold. For a similar reason it is necessary to have the bed-room kept warm for several days after the operation is performed, and scrupulously to avoid draughts or chills due to insufficient clothing. The accidents to be

avoided during tracheotomy are several in number, as well as the complications which may arise subsequently.

Amongst the former I might mention spasm of the glottis from a faulty position of the neck, entrance of air into a large vein, and almost instantaneous death due to reckless haste and want of proper precaution; inability to introduce the tracheotomy tube for different reasons, the more frequent of which is a too short or too lateral incision of the tracheal walls, and last but not least, the inpouring of blood into the air-passages, when the hemorrhage is profuse after the opening of the trachea, and cannot be quickly arrested. After employing pressure, cold, styptics, etc., in this last accident, do not forget to introduce a suction-syringe into the outer orifice of the canula, and withdraw whatever of blood can thus be taken hold of. As a last resort, as I have already mentioned, make use of the faradic current and continue to apply it so long as there is any evidence of lingering vitality.

Amongst subsequent complications it is proper to note those which may arise in connection with the canula, which may become detached as previously remarked, or may be, if too short, thrown out of the trachea during a paroxysm of coughing. This accident occurred twice with the first patient I have shown you this afternoon, and on one occasion he was very close to suffocation on account of pressure of the trachea by the canula, which was still in the wound and abutted as it were against the tracheal walls. Lung complications of different sorts—bronchitis, pneumonia, collapse—are to be dreaded during the first few days following the operation, unless special care be observed. They are to be treated, if they declare themselves, according to ordinary principles.

If, owing to the small size of the tracheal wound, or to the length of time and difficulty of introduction of the canula, emphysema of the neck occurs, it is absolutely necessary to have a tube of more than the ordinary length, so that the trachea can be reached and filled by it. If the canula become obstructed with false membrane or inspissated mucus, try first to remove it with a pair of long, curved, narrow forceps, and if this means fail, do *not* hesitate to remove the inner, and then the outer canula, if required.

It is often a useful thing, both during the operation and at a later period, to have a guide for the outer canula, so that all difficulty arising from the use of the ordinary form of dilator may be obviated.

FIG. 2.

This I have accomplished with the guide which I hold in my hand, and which was constructed for my use more than a year ago. It is not an original idea, but is none the less practical, and I commend it strongly to you all. My second patient, who has carcinoma of the larynx, I will speak of at our next meeting.

OLEATE OF ZINC, either as an ointment or in solution, is highly recommended by Dr. Crocker, of London, in eczema, chronic ulcers, etc.

AN OBSCURE CASE OF ABDOMINAL DISEASE.

A CLINICAL LECTURE

Delivered at the Pennsylvania Hospital, on December 18th, 1878.

By JAMES H. HUTCHINSON, M.D.,

ONE OF THE ATTENDING PHYSICIANS OF THE HOSPITAL.

(Prepared for THE MEDICAL RECORD.)

THE HISTORY AND SYMPTOMS OF THE CASE—ABDOMINAL SWELLING WITH ASCITES—ASPIRATION—THE DIFFERENTIAL DIAGNOSIS BETWEEN CIRRHOSIS OF THE LIVER AND CHRONIC PERITONITIS—THE CASE PROBABLY AN INSTANCE OF THE LATTER DISEASE—ITS TREATMENT.

I SHALL bring before you this morning a patient who has been in the medical wards of the hospital for nearly a year, and consequently under the care of all of my colleagues. Notwithstanding the length of time she has been under observation, there is still some difficulty in deciding as to the nature of the disease from which she is suffering, or, to speak more correctly, has been suffering, because at present there is no evidence of the existence of active disease, but rather of the results of disease. Without further prelude I will call your attention to the important parts of her history:

She is a Swede by birth, about 30 years of age, and was at the time her illness began employed as an attendant at the department for the insane, of this hospital. She appears to have no hereditary tendency to disease of any kind. Her mother died from the effects of a miscarriage, but her father is living, and, although advanced in life, is in good health. Of her brothers and sisters, two died in infancy; another at the age of fifteen, of what would seem to have been acute Bright's disease; and a fourth, of consumption, of which, she assures us, there has not been another instance in her family. She herself had a perfectly healthy infancy and childhood, interrupted only by an attack of measles, from which she made a good recovery. At the age of nineteen she menstruated for the first time, but this function seems to have been in the main healthily performed afterwards up to the time of her marriage, seven years ago. Her only child was born about a year after, and is consequently now six years of age. He, it is said, is perfectly healthy, and so, she assures us, is her husband.

In the summer of 1876, while in charge of a violent patient, she was thrown with some force against an iron bedstead, striking the lower part of her abdomen. This injury was followed by a good deal of pain and tenderness in this region, and by menorrhagia, which continued up to the time of her admission, and has occasionally been present since. She attributes a good deal of importance to this injury, and says that she has never felt perfectly well since. It appears, however, that it interfered with her duties as attendant for a short time only, as she continued in the employ of the hospital, often losing sleep and rest, until a short time before her admission here.

When she first came under our observation, it is said that pain and tenderness over the abdomen, at first more marked on the right side, below the position of the liver, were the most prominent symptoms; together with this, there was an occasional hemorrhage from the womb. Shortly afterwards a gradual enlargement of the abdomen was detected, which, upon examination, was found to be due to an effusion into

the peritoneal cavity. At the time, percussion showed that the hepatic dulness was diminished in extent. The urine was passed in small quantities—sometimes not more than a pint a day being obtained from her, but it contained neither albumen nor sugar, and appears to have been healthy in every respect. The symptoms do not seem to have presented any variety at first; the pain and tenderness persisted, and the abdominal effusion increased gradually in amount, until it was thought better on the 24th of last June to remove it by operation, when nine quarts of a clear yellow liquid were drawn off. Since this time there has been, I am told, no evidence of a reaccumulation, and at the present time I feel quite sure that there is no liquid in the abdominal cavity.

There was also at one time a slight effusion into the right pleural cavity, but this must have been long ago absorbed, as there is no evidence of its existence now. Moreover, a careful examination of the chest shows that there is no disease either of the lungs or of the heart. One of my colleagues some time ago recognized the presence of endo-cervico metritis, and this still exists, though in a less degree.

These, then, were the prominent symptoms presented by the case when I first took charge of it about six weeks ago. Since that time I have studied it closely, but I am willing to admit that I am still puzzled by it. In order that I might examine her more thoroughly, I placed her under the influence of ether, but could not even then discover any condition which I could regard as positively the cause of the previous effusion. In the right iliac region there was a feeling of greater resistance to the fingers than upon the left side, and when I made a vaginal examination, I thought I could feel an indurated mass on the right side, between the fingers in the vagina and the hand on the abdomen; and the other physicians who made this examination with me, confirmed me in this impression.

To recapitulate the prominent symptoms presented by the case: we have in a strictly temperate woman, following an injury of some severity, menorrhagia, pain and tenderness over the whole abdomen, and a gradually increasing ascites, which, however, after having been removed by tapping, never reappeared. With these there are at the present time obstinate constipation, requiring the constant exhibition of cathartics to overcome it; diminished dulness in the hepatic region, especially marked in the right mammary line, but not so much so in the infra-axillary region; and the signs of slight enlargement of the spleen. The stools are, however, of good color; in other words, there is no reason for believing that there is diminished secretion of bile. The patient still passes rather a scanty amount of urine; but its reaction to every test is healthy. While there have been at times symptoms indicative of gastric disturbance, these have not been marked, and at the present time may be said to be absent.

THE CASE NOT ONE OF CIRRHOSIS OF THE LIVER.

Such is, in brief, the history of our patient. Can we explain the symptoms which she has presented since her admission into our wards, and especially the occurrence of ascites? I need hardly say to you, that the most frequent cause of abdominal effusion, especially when unaccompanied by dropsy elsewhere, is disease of the liver, particularly that form of it which is known as cirrhosis. This disease is, as you are aware, marked by contraction of the liver, and, in consequence of obstruction of the hepatic vessels, by great congestion of the portal circulation. This con-

gestion must, of course, relieve itself in some way, and this is generally by effusion of serum into the peritoneal cavity. There are certainly some of the symptoms of this condition present—for instance, there is diminished hepatic dulness, and there are also the signs of splenic enlargement; the latter is, however, not decided, since it is only discoverable by careful percussion. I am therefore disposed to attach very little importance to it as a sign in this case. If there existed decided congestion of the portal circulation, the spleen would unquestionably be much more enlarged than it is.

There is also no distention of the superficial abdominal veins, such as is found in this condition, and which we should expect to see in a case in which some relief to the congestion of the portal circle had occurred as indicated by the failure of the effusion to reaccumulate. Moreover, the patient is a strictly temperate woman, and in making this statement I do not wholly rely upon her assertion to that effect, as it is corroborated by those who knew her in the other department of this institution. Now, while I will not go so far as to say that cirrhosis is never met with in a temperate person, I unhesitatingly maintain that its occurrence is rare. Many of the other symptoms of this disease are also absent. I have called attention to the fact that there are no evidences of disturbed digestion other than the obstinate constipation. There is also none of that peculiar pallor of the surface so often seen in cases of cirrhosis (especially in those which have run so prolonged a course as this has), which to an experienced eye is often alone sufficient to indicate its presence. It is rare, too, to find patients complaining of so much pain and tenderness upon pressure as has been persistently present in this case since I assumed charge of it; I certainly have never met with them in the many cases I have seen here and elsewhere. Occasionally, after tapping, a little suffering is caused by an examination of the abdomen; but this usually ceases in the course of a day or two. Jaundice has also never been present even in the slight degree in which it is occasionally seen in cirrhosis.

CURES IN ADVANCED CIRRHOSIS INFREQUENT.

Finally, cures in advanced cirrhosis of the liver must be very infrequent. They have certainly never come under my observation, and I do not find them reported as occurring by writers on diseases of the liver. Even an arrest in the course of the disease is rare when it has gone so far as to produce ascites. Indeed, it appears to me inconceivable that there can be contraction of the liver in this case in the absence of dropsy, of serous diarrhoea, and of an increased secretion of urine. The diminished dulness in the hepatic region is certainly difficult to explain, I admit, on any other hypothesis; but it alone does not warrant the diagnosis of cirrhosis. It may possibly be due to a slight alteration in the position of the liver, brought about in a way I shall later explain.

There is a condition which is known as peri-hepatitis, which also gives rise to abdominal effusion. In this disease the obstruction in the portal circle occurs as the result of inflammation, not in the interior of the liver, as in cirrhosis, but at the point of entrance into it of the portal vein. But this disease is characterized by a rapid accumulation of fluid, so that it is often necessary to remove it as often as ten times in the course of the year. Not many weeks ago I brought before you the liver of a patient who had died of this disease. You will recollect that I then told you how frequently it had been necessary to have recourse to the operation of tapping, and that I alluded to an-

other case which had been under my care with precisely the same history. I also told you that in the former case there was distention of the superficial abdominal veins, and decided enlargement of the spleen, both clearly indicating the existence of portal obstruction, and rendering the diagnosis comparatively easy. I will not dwell further upon this disease, because much that I said while discussing cirrhosis is equally applicable to it.

I mention, simply for the purpose of dismissing it from further consideration, cystic diseases of the ovaries as a possible cause of the dropsy in this case, because there never seems to have been any doubt in the minds of my colleagues that the fluid was in the peritoneal cavity, and the recognition of this fact is generally sufficiently easy. Moreover, it is certainly rare for an ovarian dropsy to disappear after a single tapping.

THE CASE PROBABLY ONE OF CHRONIC PERITONITIS.

We have therefore to find some other cause for the ascites. In reviewing the history of the case, it seems to me more probable that this was due to chronic peritonitis, rather than to any other cause. It was formerly doubted whether chronic inflammation of the peritoneum could exist independently of tubercles, but at the present time the majority of good observers agree that it does occasionally occur. Indeed, Dr. Hilton Fagge goes so far as to say, in the twentieth volume of Guy's Hospital Reports, that for every two cases of cirrhosis of the liver treated in the wards of that hospital there is one of chronic peritonitis, causing ascites. This, judging from my own experience, is a statement which few hospital physicians would corroborate. Still, it shows that the disease is met with occasionally, and justifies us in attempting to explain the symptoms in the present case by referring them to it as a cause.

We have had here, you will remember, an injury to the abdomen which gave rise to menorrhagia, and probably also to inflammation of the womb. At the present time there is only endo-cervico metritis discoverable; but an examination made shortly after the blow might possibly have revealed the existence of a more extensive lesion. Now this metritis, perhaps in consequence of overwork, probably set up an inflammatory process in the adjacent peritoneum, which may have gradually extended until it had involved a large portion of the membrane. I look upon the presence of the indurated mass in the right iliac region as confirming this view. Indeed, there is nothing in the case which can be regarded as opposed to it, except the diminished hepatic dulness, which is probably due to a slight alteration in the position of the liver, brought about, possibly, by the results of inflammation in its neighborhood. Chronic peritonitis is often attended by but little effusion, but that this is not invariably the case is shown by the fact that many cases are reported in which it has been necessary to have recourse to tapping. In most of these cases, also, but one operation was required. The inflammation subsiding, leaves the membrane spoiled, as Sir Thomas Watson expresses it, for the purposes of absorption, but with no tendency to pour out any more liquid. The pain and tenderness which have been such prominent symptoms, I need not tell you are common enough in chronic peritonitis, and so is constipation. The disease as it is, does not necessarily cause obstruction to the portal circulation—need not give rise to distention of the superficial abdominal veins. The fact, too, that the patient is slowly im-

proving, is in favor of the view I am now taking of the case. There is no fever, and no excitement of the pulse; indeed, no active symptom of any kind. The discomfort which she undoubtedly suffers is therefore probably due to the presence of adhesions which interfere with the functions of the bowels.

The disease is, in all likelihood, not due to the presence of tubercles in the membrane, because there are no evidences of the existence of consumption, and, moreover, the patient is not hereditarily predisposed to this disease.

In regard to the prognosis of this case, the improvement which has taken place since it has been in the hospital, and indeed during the last few months, leads me to hope that the patient will eventually recover, if not perfect health, at least strength enough to enable her to gain her livelihood.

THE TREATMENT OF THE CASE.

The treatment in this case, if my view of its nature is correct, must be confined to sustaining the patient's strength and relieving her of the constipation and pain, both of which are the cause of a good deal of suffering. For these purposes she has taken various tonics and purgatives, as well as anodynes, since her admission into our wards. At the present time she is taking a pill containing one grain each of extract of aloes and extract of hyoseyamus with one-tenth of a grain of extract of nux vomica—a prescription which was original, I believe, with Dr. T. G. Thomas, of New York, and which, so far, has answered the purpose for which it was prescribed. As the urine has been of late rather scanty, she has been taking acetate of potassium and compound spirits of juniper. The pain yields only to morphia, either given by the mouth or hypodermically. Various applications have been made to the abdomen, but very little relief seems to have been obtained from them. At an earlier stage of the disease it might have been well to have used some mercurial ointment. Dr. Fagge speaks highly of the *linimentum hydrargyri*, but the time has passed when it would be at all likely to be of any service.

I have thus shown, as fully as my time will allow, the difficulties which surround the diagnosis of this case. It may be that I have come to a wrong conclusion in regard to its nature, and that it will eventually prove to be one of disease of the liver, but with the present light we have upon it, I cannot think this at all probable.

[Since the delivery of the above lecture, the patient has steadily continued to improve, and has gained so much strength that her detention in the hospital is no longer necessary. Her attacks of pain have become much less frequent and severe, and the menorrhagia has been to some extent relieved. Her appearance at the present time indicates an almost entire restoration to health, and is certainly very different from that which usually accompanies serious organic disease of the liver.

No important change has been made in her treatment except that she has been taking for some time past Trommer's Extract of Malt, from which she seems to have derived much benefit.

It has recently come to light that one of the attending physicians of the hospital, who saw her while the acute symptoms were still present, believed that she was suffering from entero-peritonitis. This fact, of course, fully confirms the lecturer's view of the nature of the case, and renders it almost certain that his diagnosis was correct.—Reporter.]

Original Communications.

AN INSTRUCTIVE CASE OF OVARIOTOMY.

THE WALL OF A MISPLACED BLADDER INVOLVED IN THE INCISION—DEATH.

BY LEROY McLEAN, M.D.,

SURGEON TO TROY HOSPITAL, TROY, N. Y.

Miss A., *æt.* 24, had always been healthy previous to 1873. During the spring and summer of that year she was under treatment for uterine disease by her family physician. At this time she suffered from pelvic pains and "bloating of the abdomen."

In the winter of 1873 was perceived the first indication of a growth in the left iliac fossa. The development of the tumor was slow. In 1876 it had attained such dimensions as to displace the neighboring viscera, causing the usual symptoms—dyspnoea, flatulency, aggravated digestion, etc. The catamenia continued with more or less regularity. I first saw her in August, 1878. She was not much emaciated, though the expression of countenance was anxious. The form of the abdomen was quite uniform, with a slight bulging above the umbilicus. She measured, at the umbilical level, thirty-six inches. The percussion sound was dull over the anterior surface of the abdomen. Fluctuation could only be distinguished over a small portion to the left of the median line below the umbilicus. The sound entered but an inch into the cavity of the uterus. Marked ante-flexion of that organ could be detected by vaginal examination. Oct. 7th, assisted by Dr. Schuyler, and Drs. Vanderveer and Merrill, of Albany, I operated for the removal of the tumor. Before proceeding to the operation a large aspirating-needle was introduced to the left of the median line, and a quantity of fluid, having the consistency and color of molasses, withdrawn. The bladder was then evacuated. The incision was commenced half an inch below the umbilicus, and extended down two and one-half inches. At the lower angle of the incision, at a depth of three-quarters of an inch from the surface, I cut into what appeared to be a cyst in the abdominal walls, which contained about two drachms of pale fluid. The edges of the incision did not retract as they usually do when the abdomen is tense, and not liking the indications presented, and not being thoroughly satisfied as to what we had to deal with, the incision was carried upwards to a point on a line and to the right of the umbilicus, when the unmistakable ovarian sac was reached. Using the finger as a director, the opening was completed below, and the tumor removed. Suppuration had begun in a portion of the sac. It had two strong omental adhesions, one of which necessitated the application of a ligature. The tumor was of the multilocular character. The pedicle was secured with a silk ligature, and returned, it being too short to admit of clamping. Then was discovered the condition shown in the drawing, and the injury done to the bladder, it having been cut through on its anterior and posterior surfaces down to the point marked "C"—the lower end of incision. The anterior surface was strongly adherent to the abdominal wall. It was not adherent to the tumor. In completing the incision from above downwards the finger used as a director had passed behind the bladder (its walls being then in *close contact*

from pressure of tumor behind), and the injury done as shown. The bladder was repaired with interrupted silk sutures. The adhesions of its anterior surface to the abdominal walls were not disturbed. Abdominal incision closed with silver wire.

The patient was carried to her bed, and one hour after a soft rubber self-retaining catheter (which we were obliged to send for at some distance) introduced, and two ounces of urine withdrawn, showing that the bladder was still capable of performing that portion of its functions. The catheter was left *in situ*, the urine being thus allowed to escape as soon as secreted. Previous to the introduction of the catheter she had expressed a desire to micturate.

At 10 P.M., ten hours after operation, her condition was good. She had rallied, but complained of feeling very tired. She expressed a desire for food. Pulse, 112; temp., 100°.

5 A.M.—Pulse, 125; temp., 101°. She has begun to show evidences of approaching dissolution. She gradually sank from this hour, death occurring at 7 P.M., thirty hours from time of operation. Her temperature did not at any time exceed 101½°. The secretion of urine was normal.

Post-mortem, in the presence of Drs. Vanderveer, Ward, Snow, Edward Hun, and Schuyler: Primary union of abdominal incision; no evidence of peritoneal inflammation; the bladder intact, good primary union, and no escape of urine into the cavity of the abdomen. The effort of nature at repair beautifully shown in portion of omentum which had been ligated—a fibrous clot had been thrown out which covered the ligature and formed a strong adhesion of cut end to a fold of the intestine. There was no evidence of sloughing of the pedicle. The adhesions of bladder to abdominal wall so firm that they *cannot be separated without tearing that viscus*. The uterus was ante-flexed and bound down by strong adhesions.

The only theory I have to offer in explanation of the malposition of the bladder is, that the uterus having been ante-flexed to the degree it was, the bladder under distention would naturally enlarge in the direction where the least resistance was offered. Her friends state that in 1876 she went from here to Chicago, and that she did not leave the cars during the journey. Now it is well known that women will sometimes go for many hours without micturating, and it may have been so with our patient, and as a result the distended bladder crowded itself upwards between the tumor

and the abdominal walls, and was held there mechanically by pressure of the tumor, after it had been emptied. It may be that the condition was a congenital one.

Had the tumor been adherent to the bladder there might be no doubt as to the cause of the anomaly. It might be suggested, as a wise procedure hereafter, to pass a sound into the bladder and the exact condition of that organ ascertained before operating.

A CASE OF EXOPHTHALMIC GOITRE.

By JOHN A. LIDELL, M.D.,

OF NEW YORK.

This disease is by no means common, and therefore the publication of the following case may do some good. The notes were taken at the time. Miss C., a maiden lady in good circumstances, about thirty-four years old, of stout build, dark hair, dark eyes, and brunette complexion, whose home was in the country, applied to me for treatment *March 15, 1873*. She has a large bilobate tumor in the throat, obviously developed in connection with the thyroid gland; the right lobe considerably larger than the left. Eyes also much protuberant, giving her a strange, staring appearance, with pupils somewhat dilated, but respondent to light. Says she first noticed the swelling in her throat about three years ago. During the last year, however, it has grown very rapidly. First noticed that her eyes were becoming too prominent about one year ago. The protrusion is increasing, and at times the eyeballs feel as if they would burst out of her head. Then she gets relief by pressing them back into the orbits with her fingers. As to the goitre, it sometimes is considerably larger than at others; it sometimes, also, gives rise to choking sensations and difficult breathing, or suffocative attacks, with dread of impending death. Is very nervous and easily fatigued. Countenance and lips rather pale. Is subject to dizziness, and is short-breathed, especially on making exertion. Is *not* liable to palpitation of the heart. Menstruation regular, much more so than formerly. Appetite good. Bowels inclined to be constipated. Suffered much from bleeding piles last fall, but of late not at all. Pulse about 90, full and hard. Heart beats strongly, but without abnormal murmurs. On examining the goitre with my fingers I find that each lobe of it pulsates synchronously with the heart, distinctly, strongly, and expansively, *i. e.*, in an outward direction, and imparts to the touch a jarring or thrilling sensation. On listening to it with a flexible stethoscope, a rather loud bellows-murmur is heard in every part of each lobe. Advised the application of ice to the goitre daily, and the internal administration of the following:

℞. Pulv. digitalis (opt.) gr. xij.
Ferri redacti (Quevenne) gr. xvij.
Mucilag. g. tragacanth. q. s.

Ut ft. pil. equal. No. 18.

S.: Take one pill three times a day, before meals.

Also:

℞. Pil. rhei comp. (sugar-coated), No. 6.

S.: Take one pill daily after dinner, until the constipation is relieved.

March 21.—Patient feels rather better, and is less nervous; has not had an attack of choking since she called on the 15th; goitre unchanged: has not ap-

plied the ice; pulse 90 (by count) and soft. Prescribed the following:

℞. Extract. ergot. fluid. (Squibb),
Tinct. digitalis ʒiij.

S.: Take ten drops three times a day, in water.

Also:

℞. Pil. rhei comp. (sugar-coated), No. 6.

S.: Take one pill daily at bed-time.

March 29.—Patient says she is less nervous; finds now that she can write without shaking; exophthalmos the same; pulse 90, by count, but larger; goitre smaller; has much pain in uterine, sacral, and lumbar regions, apparently due to the ergot; says that on the whole she feels decidedly stronger and better. Applied the ice yesterday to the goitre, which, she thinks, caused it to shrink, but gave her a severe fit of suffocative breathing that followed the application thereof. Ordered the ice to be applied again on Monday (31st), and to call on me Tuesday.

Also:

℞. Pulv. digitalis (opt.).

Quinia sulph. ʒiij.

Mucil. g. tragacanth. q. s.

Ut ft. pil. equal. No. 24.

S.: Take one pill three times a day.

April 3.—Patient says she feels still better; is decidedly stronger and less nervous; expression of countenance less anxious and more composed; eyes rather less protuberant; pulse less frequent and more natural in volume; after resting it is 84 by count; the goitre, especially its right lobe, decidedly diminished in size, and firmer in feel; bellows-murmur in right lobe also not so loud. Injected subcutaneously over right lobe of the goitre six minims of Squibb's extract. ergot. fluid. It caused some burning pain at the place of injection, but not so much as I had expected. Directed the pills of digitalis and quinine to be continued. She had failed or neglected to apply the ice again, partly from want of facilities to do it, and partly from dread of its possible effects, inasmuch as on a previous occasion it was attended with a paroxysm of choking and extreme dyspnea.

April 25.—Both lobes of the thyroid (goitre) now free from thrill, quite hard, and considerably diminished in size. Prescribed:

℞. Granulæ acid. arseniosi (sing. gr. $\frac{1}{2}$), No. 100.)

Signa: Take one granule night and morning.

On the next day she returned to her home in the country feeling pretty well, since which time I have not seen her. I heard, however, through one of her friends who had seen her, that the improvement was permanent.

What struck me most in the management of her case was the good effect of the ergot, especially when it was employed subcutaneously at the seat of the swelling in her throat.

I have delayed the publication of her case because, hitherto, I have hoped to see her again, and to find by personal examination the result of the treatment.

46 WASHINGTON SQUARE, JANUARY 2, 1879.

FERMENTS IN PANCREATIC JUICE.—Th. Defresne (*Répertoire de Pharmacie*) has separated three different ferments from the pancreatic juice, each of which has different functions and properties: *Amylopsine*, which converts starch into sugar; *steapsine*, which splits up fats; *myopsine*, which dissolves albumen.—*The Doctor*, Nov. 1, 1878.

A CASE OF POISONING BY ACONITE.

By F. H. O'BRIEN, M.D.,

NEW YORK.

THE patient, Miss M—, æt. twenty-four, unmarried, took through mistake half a drachm of the tinct. aconiti rad., which was followed in twenty or thirty minutes by a sense of warmth in the stomach, nausea, and oppression of breathing. Shortly after this followed numbness, tingling, and slight muscular weakness. She did not attribute her feelings to the drug, and in one hour from the time it was taken (4.30 P.M.) the dose was repeated. She started soon afterwards to walk a distance of two miles, and did not complain until about half way. On reaching her destination she began to stagger, and was soon completely prostrated. Her voice became very weak, and she complained of cephalalgia and lancinating pain in different portions of the body, but particularly in the joints. I was sent for, and arrived at 6.40 P.M. Learning that the patient had taken a poisonous dose of aconite, I administered the usual emetic, which was swallowed with great difficulty. I sent for Dr. Wm. H. Studley, who quickly arrived. I found the patient in the following condition: Axillary T. 97½°, P. 32; R. 10. Pupils dilated, extremities cold, loss of consciousness, extreme pallor of face with expression of great suffering, and there was a twitching of the mouth and eyelids. Emesis was produced. The stomach contained a considerable amount of fluid, which had an odor of alcohol. The retching continued, and her condition each moment grew worse, the pulse becoming frequent and irregular, and respiration more difficult. By consent of Dr. S. I injected hypodermically fifteen mins. Magendie's sol., just after which (not exceeding one minute) the symptoms became more alarming still: she having a slight convulsion. There was a spasmodic contraction of the laryngeal muscle, respiration ceased, and the pulse was imperceptible. Dr. S. did not observe me inject the morphia, and remarked that if I had not already done so it was useless to inject it.

She was a dying woman; respiration had ceased, the feeblest pulsation could not be detected, the body was cold to the touch, and we had every evidence of impending dissolution. We had lost all hope in the case, but were endeavoring to detect a feeble impulse of the heart, when suddenly and to our surprise the pulse sprang up, about the rate of forty per minute. The laryngeal muscles were relaxed and respiration began. Very soon the cheeks were flushed, and heat returned gradually to the extremities.

The thermometer was again placed in the axilla, and registered 98½°. The retching continued, and in half an hour the pallor returned, there was general muscular tremor, and the pulse became frequent, and irregular as before. Ten mins. Magendie's sol. was injected, and an enema containing twenty grains carbonate of ammonia and one ounce of brandy. She soon rallied as before; this time recovering consciousness, and complained of cephalalgia, burning sensation in the stomach, and severe pain in different parts of the body. At ten o'clock P.M. I injected ten mins. more Magendie's sol., which seemed to quiet her, and at twelve o'clock she was asleep. The bladder had been evacuated four times since eight o'clock.—15th, six A.M., T. 99°; P. 80. Has vomited only after the enemata, which were repeated at intervals of two hours. She complained of great muscular soreness, and movement of the body is painful. She is very weak, her grasp being scarcely perceptible. Champagne and mucila-

ginous drinks were given, and the enemata continued, but at longer intervals.

Four P.M., T. 99½°; P. 72. Vomiting has ceased, and but little nausea. Diuresis has continued, and she complains for the first time of pain in the region of the kidneys, paroxysmal in character, lasting but for a few moments at a time.—16th, ten A.M.: T. normal; P. 80. Has rested well since evening before; diuresis diminished; no pain in region of the kidneys; cephalalgia and muscular soreness remaining.

17th, ten A.M.—Patient much improved; T. normal, P. 80. Has taken food in fluid form with relish. Muscular soreness diminished, and but slight cephalalgia, which remained for several days. Two days later she complained of a peculiar sensation at the roots of her teeth, and diarrhoea, which symptoms lasted but a short time. The patient gradually improved, the muscular soreness being last to disappear. I will not speak of the physiological action of opium and aconite, as time and space will not permit; but I think that the case presented illustrates the antidotal virtue of opium in aconite poisoning.

No. 1115 MADISON AVE., HARLEM.

Progress of Medical Science.

ON THE TREATMENT OF MORBUS COXARIUS BY A NEW METHOD.—Dr. Joseph C. Hutchison, in an article (*American Journal of Medical Science* for January, 1879), advocates the following plan of carrying out the indications for the treatment of morbus coxarius, which he considers to be: (1) to secure immobility of the joint; (2) to procure extension of the limb; (3) to take off from it the superincumbent weight of the body; (4) to provide means to enable the patient to take exercise in the open air. He considers that immobility is obtained by the rigidity of the joint, and that this continues until nature says it is no longer necessary. To obtain extension of the limb and to remove the weight of the body he resorts to the following device: On the shoe of the sound limb an iron sole is applied, three inches high, so as to raise the foot from the ground. This elevated shoe and a pair of crutches constitute the apparatus. As the patient stands on his crutches the diseased limb is suspended. The shoe should be high enough to prevent the toes of the affected limb from touching the ground. By these simple means we fulfil all the indications for the mechanical treatment of hip-joint disease. Immobility is obtained and friction prevented in the manner above indicated—chiefly by rigidity of the periarticular muscles. Extension made by the weight of the suspended limb, which is greater than the weight ordinarily employed for extension, is quite sufficient to relieve the inflamed parts from pressure and pain, and to overcome deformity of the limb even though it be considerable; the weight of the body is removed from the diseased joint, and the patient can enjoy all the benefits of open-air exercise.

ANOTHER ANTI-EMETIC.—The value of spiritus nucis juglandis, "spirit of walnut," in vomiting, is much insisted on by Dr. E. Mackey. He has used it in various forms of vomiting, and found it successful after other things failed. He gives it in drachm doses three times a day.—*The Practitioner*, Dec., 1878.

DOUBLE HEARING—AUTOPHONY AND TINNITUS AUDIUM—CAUSES OF.—Dr. Samuel Sexton (*Transactions of the American Otological Society*, 1878) seeks to

elucidate some of the hitherto unexplained problems of audition, especially those connected with double hearing, autophony, tinnitus aurium, hearing better in a noise and the contrary. He believes that these conditions most frequently depend on derangement of the conductive apparatus rather than on pathological conditions of the inner ear, as is usually maintained. The various anomalies of audition, double hearing, etc., are of much greater frequency than is generally supposed. On examination it is found that some patients can hear their voice in two distinct ways—first by the medium of the external air and external meatus after the sound has issued from the mouth; second, by conduction from the vocal cords directly through the intervening tissues. Dr. Sexton believes that this occurs in cases where the articular surfaces of the malleo-incudal joint are separated as a result of disease. When this occurs in one or both ears much confusion is apt to result.

Musical persons sometimes complain of hearing musical notes falsely. Most authorities explain this by referring the abnormality to the auditory nerve itself. Dr. Sexton, however, believes it is due to imperfect conduction of the sound by derangements of the conductive apparatus.

Tinnitus aurium he explains as due to the sound waves of circulation in the neighborhood of the ear—but not in the labyrinth—which ordinarily are not heard, but when the malleo-incudal joint is separated these vibrations of sound reach the acoustic nerve through the incus and stapes. Dr. Sexton concludes that the operation suggested by Bonnefont and others, establishing a permanent opening in the drum-head, is not likely to prove as frequently useful as was at first anticipated. He further believes that the Politzer air-bag is sometimes liable to do injury by unduly stretching the membrana tympani when atrophied by disease.

TREATMENT OF WOUNDS BY DRY AND INFREQUENT DRESSINGS, REST, AND PRESSURE.—Mr. Sampson Gamgee, in a clinical lecture in the *Lancet* for Dec. 21, 1878, advocates the treatment of wounds by dry and infrequent dressings, uniform pressure, and absolute rest. The following is his plan: He unites the edges of the wound with silver sutures; a gauze and oakum pad is then placed over the wound, the limb enveloped in cotton-wool sufficiently to protect the bony prominences, and immobilized by lateral and posterior moistened pasteboard splints from foot to hip. A gently compressing bandage completes the dressing. He gives the histories of three cases of injury about the knee joint, treated on this plan, and all did well. In one the tendon of the quadriceps extensor was completely divided, the intercondyloid space exposed, and the finger could be passed underneath the patella. The wound was not laid bare until the ninth day; healing was then perfect. There had been neither pain nor rise of temperature. A case of extensive contused and lacerated wound of head was also successfully treated on this plan.

In order to compare this plan with Lister's, Mr. Gamgee lately excised the elbow-joint in two patients on the same day. In one case the skin was unbroken, and in the other a sinus led down to a suppurating joint. He took the latter for the dry dressing, as its condition was not looked upon as a favorable one for the antiseptic method. The suppurating case was also the more unfavorable one of the two because its subject was altogether a weaker man. On the evening before the operation the temperature of these patients was about 98°. November 23d he excised both elbow-joints, making in each case one longitudinal incision.

About the same amount of bone was removed from each, namely, of the humerus, radius, and ulna. In the dry case wetting the wound was carefully abstained from. Its surface was lightly brushed over with styptic colloid after twisting one vessel. Fine points of silver suture accurately approximated the edges, except in the centre, where a gap was left for a loop of drainage-tube, which passed through it and the opening on the radial side which had led into the joint before operation. The dressing consisted in strips of lint, soaked in styptic colloid, applied so as to assist the stitches, a gauze and oakum pad outside the joint, a covering of cotton-wool half an inch thick over the whole limb, which was immobilized in the straight position by means of moist pasteboard splints extending from the tips of the fingers to the shoulder, and moulded to the limb under a gently compressing bandage. The other case was treated according to the Lister plan, carried out in all its details. Four vessels were secured with carbolized catgut, the wound united and a drainage-tube of the same thickness as in the first case was inserted. The carbolic case was dressed whenever permeation was observed through the dressings, which was daily for the first few days. The dry case was dressed the first time at the commencement of the fourth day after the operation, when four-fifths of the wound were found healed. On the twenty-second day after the operation, there were about thirty drops of odorless pus next to the wound found in the Lister case. In the dry case the dressings were quite dry, the old sinus had all but closed, and the cicatrix was quite solid for three-quarters of its length; the elbow was flexed at a right angle, and there was no pain. The temperature, pulse, and respiration were higher in the case treated after Lister's plan than the one treated on the dry plan. Mr. Gamgee mentions the fact that the first patient rested better, and had a good night, while the second suffered pain in the arm, greatly intensified at each dressing.

The following is the record of the temperature, pulse, and respiration:

DRY REST CASE.				
	Nov. 24th.	Nov. 27th.	Nov. 30th.	Dec. 3d.
Temp. . .	102.5°	98°	98.4°	98.4°
Pulse. . .	96	80	81	76
Resp. . .	34	24	24	26
CARBOLIC SPRAY CASE.				
	Nov. 24th.	Nov. 27th.	Nov. 30th.	Dec. 3d.
Temp. . .	103°	102°	99.5°	98.4°
Pulse. . .	120	108	88	106
Resp. . .	30	24	22	22

A system of treatment which requires that whenever the discharge is seen to come through the dressings, they are to be changed under carbolic spray, is opposed to the great principle of local and constitutional rest, subjects the patient to a great deal of pain and the surgeon to a great deal of trouble.

TREATMENT OF ONYCHIA SCROFULOSA.—In the treatment of onychia scrofulosa, which is always accompanied by fungosities, M. de Saint-Germain employs a very simple operative procedure. It consists simply in paring off the end of the finger or toe, as one would trim a quill-pen, removing in one sweep the nail with its matrix, and the superficial portion of the phalanx with the fungosities developed on it. The resulting wound heals very rapidly.—*Jour. de Méd. et de Chir.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, February 8, 1879.

THE YELLOW FEVER INVESTIGATION.

THE Board of Experts on Yellow Fever, appointed by the Joint Committee of the Senate and House of Representatives, have submitted their report, and have therein endeavored to answer as far as possible within the allotted time the various questions which were presented for their consideration.

That the committee under the circumstances have done so well and have examined the subject in its general bearings so thoroughly, will be a matter of surprise to any who are unacquainted with the character and extent of the work. As might have been anticipated, however, the report is not yet complete. It nevertheless answers the purpose of its immediate presentation, in that it suggests the basis of that health legislation for which there is such an urgent demand. Aside from the more direct object in view, the report is interesting as furnishing some valuable scientific data based upon a careful and extended examination of the history of the recent epidemic. The majority of the conclusions arrived at serve to confirm the results of previous observations; at the same time many facts have been elicited that may be considered as new.

Without further introduction, we propose to summarize these conclusions in the order in which they are given in the report. After quoting the questions which were submitted to them by the Joint Committee, they proceed to answer them in turn. It is maintained that yellow fever is a specific disease, and is produced by the introduction in the human organism of a specific poison. The specific poison of yellow fever has never been microscopically nor chemically demonstrated, nor in any way made evident to the human senses. Nevertheless, the Board think that it is safe to assume it to be material and particulate, and endowed with the ordinary properties and subject to the ordinary laws of material substances.

Yellow fever is not a malarial disease—that is, it is not the offspring of that marsh miasm which produces paludal or periodic fevers—and there are no facts which warrant the conclusion that malarial influences contribute toward the dissemination and mortality of yellow fever in any other way or to any greater extent than they contribute toward the dissemination and mortality of other epidemic diseases. The precise nature of the favorable local conditions which seem to be necessary to the evolution of yellow fever epidemics is unknown. With the concurrence of high summer heat, atmospheric moisture, marsh malaria, and abundant filth, yellow fever often fails to swell into epidemic prevalence. Yellow fever has singular local attachments, often restricting its epidemic appearance to one portion of a city. Under such circumstances it exhibits a remarkable indifference to topographical and social surroundings. Atmospheric air is the usual medium of infection, although it does not appear that the disease has been carried to any considerable distance by atmospheric currents. In the large majority of cases the period of incubation is from two to five days. Second attacks of the disease are of rare occurrence. In its epidemic form the disease is one of warm climates and of warm seasons of the year. The specific poison is rendered innocuous by frost, and it appears probable that the temperature of boiling water is fatal to it. There is also reason to believe that the poison can be destroyed by chemical disinfectants. The fever is exotic in origin in all countries outside of the West Indies.

Yellow fever has invaded the present territorial limits of the United States, according to the testimony of existing records, in 88 different years. For 77 of these 88 years there is evidence, more or less complete, of importation, and in 71 out of these 77 the evidence points to the West Indies as the source of the infection. Four times—namely, in 1839, 1844, 1847, and 1867—the infection has been traced to Mexico, but in 1867 it was also traced to the West Indies. It is said that in 1800 and 1838 the disease was brought from Demerara, but in 1800 it was also brought from the West Indies. The fever of 1870 is attributed to Honduras.

The board knows of no facts which establish the proposition that yellow fever has become indigenous or epidemic in any part of the United States; there are facts which seem to warrant the inference that in some of our southern cities the specific poison of the disease, when hidden away from the cold in sheltered places, may live through a mild winter and give rise during the succeeding summer to scattered cases of the fever. It would seem to be theoretically probable that these scattered cases would, in their turn, give rise to an epidemic; but the proof that they have ever done so is not conclusive.

In its migrations the fever follows lines of travel; its poison is carried across seas by ships, cargoes,

crews, and passengers; into the interior by steamboats, cars, wagons, baggage, and infected passengers. The board do not attempt to decide to what extent the body of the sick person is accountable on the one hand, and to what extent the clothing and baggage are responsible for it on the other. Outbreaks of the fever have been, however, directly traced to infected articles of clothing and bedding. Ordinary merchandise, in original and unbroken packages, may become infected and lead to outbreaks of yellow fever.

Based upon the facts given, the board recommend the following measures for preventing the introduction of yellow fever into this country, the same measures applying also to cholera: First, the surveillance of ships at the time of sailing from infected ports to any port of the United States; secondly, their inspection, detention, and disinfection, when found necessary, upon reaching our coast.

The following scheme of quarantine, constructed from a purely medical point of view, is also recommended: This scheme contemplates two classes of medical officers—one class for foreign service and one class for home service. Medical officers of health for foreign service should be stationed at the various foreign ports having commercial relations with the United States, where yellow fever, cholera, or other epidemic infectious diseases prevail. Their duties should be to acquaint themselves thoroughly with all diseases usual to, or at any time prevalent in or around, the respective places to which they are assigned, and to make to a chief health authority at Washington the same reports as are now required of consular officers by Section 2 of the National Quarantine Act, approved April 29, 1878. They should forward reports of outbreaks of cholera, yellow fever, or other epidemic diseases, and of the departure of vessels from infected ports, or of vessels having on board persons or goods from infected ports, to be communicated by telegraph, or in the most expeditious manner, to a chief health authority at Washington. It should be their further duty to obtain the medical history of all ships trading to or from their respective ports, in regard to any previous occurrence of yellow fever or cholera or other infectious epidemic disease on board, and transmit the same for the information of said health authority.

Medical officers of health for home service should have charge of quarantine stations, and should supervise inter-State travel and traffic from infected places in times of epidemic. The two classes of medical officers suggested are considered indispensable to any method of quarantine which does not involve a complete suspension of intercourse with infected ports.

The measures for preventing the spread of yellow fever, when once introduced into the United States, are classed under the following headings: Local sanitation, isolation of the sick, segregation of the well,

disinfection or destruction of the poisons, measures of personal prevention, and inland quarantine. It is a noticeable and significant fact that the board, as the result of their observations, oppose absolute quarantine, and advocate a system of protection which is entirely consistent with the safety of communities and with the maintenance of commercial intercourse with other localities.

In concluding this brief summary of a report which furnishes much food for thought and study, we would state that the Board of Experts have placed the country under obligations for the work thus far accomplished, and have, as we have already intimated, given a good basis for that intelligent legislation which is at present needed. The suggestions are reasonable and practical, and deserve careful consideration on the part of our legislators. Calling to mind the leading features of the Matthews bill for the creation of a National Health Bureau, it can easily be seen that they correspond in a very striking manner with the recommendations of the Board of Experts. This latter fact is possibly the strongest argument that has yet been offered for the bill in question.

THE PLAGUE IN RUSSIA.

THE hope indulged in by many European journals that the epidemic raging in Southeastern Russia was nothing more than a malignant type of typhus fever imported from Turkey is now pretty much dispelled. In fact, there do not seem to be any doubts that the disease is the veritable bubo-plague, and that it has gained a secure foothold in the province of Astrakhan, and is spreading panic along the whole course of the river Volga. The latest account of the origin of the pestilence is to the effect that a Cossack soldier, returning from the war to Wetlianka, a town in the province of Astrakhan, brought with him a shawl for his sweetheart. Two days after wearing the shawl the girl sickened and died with the symptoms of the plague. From that starting-point the disease spread in various directions for many days before the Russian Government saw fit to interfere by the establishment of a quarantine. Now thoroughly aroused, that government, actively aided by the people, is making use of means to check the progress of the disease. A sanitary line has been formed along the whole course of the Volga, and quarantines have been established at Sarepta, Iwanowka, Otrada, and Zaritzin. In the villages where the disease rages a cordon is established around the infected streets. The outskirts of these localities are also surrounded by soldiers preventing all communication. The efforts in the direction of the strictest quarantine are actively seconded by the people, many of whom will not even receive letters or paper money from the infected districts. The alarm seems to have spread into Europe, for Russian rail-cars are no longer admitted to Germany, and strict passport regulations will be enforced

after Feb. 10th. The Austrian Government has forbidden the importation of Russian goods except under quarantine, and is about to issue orders forbidding travellers from Russia to cross the frontier unless provided with passes from the sanitary authorities. The Porte has established a quarantine on the European coast of the Black Sea, and Roumania has decreed a similar course on the delta of the Danube. In spite of these precautions the plague is rapidly spreading, and from all accounts is making its way into western Russia. It would appear, from what we know of the general history of previous epidemics, that the progress of the plague can be stayed very materially by an efficient and careful quarantine. The weight of authority seems to be in favor of the spreading of the disease by indirect communication rather than from person to person. In this respect it bears a striking resemblance to yellow fever and cholera, both of which are controllable by a proper quarantine. It would seem, judging by the reports from Russia, that the government there has only a vague notion of what a quarantine should be. It requires something more than the penning of people in an infected town and shutting off all communication from the outside.

Reports of Societies.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 27, 1879.

DR. FREEMAN J. BUMSTEAD, PRESIDENT, IN THE CHAIR.

THE TREATMENT OF SPINAL CURVATURE BY CONTINUOUS EXTENSION.

DR. JOHN A. WYETH read a brief paper upon the above subject, and gave the history of an illustrative case.

Extension, fixation, and rest were the cardinal principles in the treatment of disease of the vertebral column, and when to those were added hygienic measures and judicious medication, we had the sum total of all the indications. The wheel-crutch and Taylor's brace indicated progress in our knowledge with reference to the treatment of spine disease, but each had its advantages and its disadvantages. The plaster-of-Paris jacket was a great stride in the right direction, and its simplicity attracted attention. Some of us supposed it to be the *ne plus ultra* in the treatment of curvatures of the spine, and that such sufferers had nothing to do but to submit to suspension by the arms and the neck, and be enveloped in plaster to be cured. But had it fulfilled this expectation, and did it meet all the indications? It came nearer than any other method of treatment which had yet been made public; but it had its faults, and those the doctor proceeded to point out. If the grip of the jacket could be uniformly maintained, it would meet all the indications. But it lost its firm hold in from seven to ten days after being applied, and therefore lost its property of maintaining the parts at rest and sepa-

rating the diseased surfaces. Such result came from two causes:

1. Atrophy of the underlying parts from pressure; and

2d. Softening and relaxation of the plaster, produced probably by absorption of bodily moisture.

The apparatus having yielded, the diseased structures came again in contact; hence arose the necessity of removing and reapplying it, an operation which, according to his experience, was at times painful and annoying. It also made pressure upon the protruding spine, and often made excoriations. Although fenestra were cut, there was danger of the discharge getting beneath the plaster and in turn give rise to excoriation, which required removal, dressing the sores, and reapplication of the apparatus. The method which he presented he believed obviated all those difficulties.

It consisted, in the first place, of a plaster-of-Paris jacket, but the jacket was made in two segments, which came nearly together at the point at which the lesion was situated.

The upper section was applied by commencing about one inch above the seat of the disease, and passing upwards. The rollers would catch upon the expansion of the thorax from below upward, and also upon the muscles of the axillæ and the scapular prominences. Then, beginning just below the seat of injury, another jacket was applied, perfectly independent of the upper one, and extended downward until it caught upon the expansion of the ilium upon both sides.

FIG. 1.

FIG. 2.

Into each jacket, while it was being applied, were fastened zinc plates, (See Fig. 1, A) perforated from both sides, so that the little spicula became entangled in the plaster, and were thus rendered practically immovable. In the centre of each zinc plate a strong iron staple was fastened (See Fig. 1, B). Three of these plates were fastened into each jacket: one upon each side of the trunk and the third over the spine at opposite points above and below the seat of the lesion. To the staples in the zinc plates extension bars (G) were fastened, which could be lengthened or shortened by means of a key (See Fig. 1, C and G). It was

the same form of ratchet, key, and lock as used upon knee- and ankle-splints used by Dr. Sayre and others.

With such an apparatus, if *extension* and *fixation* were the indications, he thought they could be constantly maintained. The bars could be extended to twice their length, if necessary, and whenever the jackets yielded, so that fixation was not perfect, a few turns of the key would so elongate them that perfect rest could be insured.

Dr. Wyeth then gave the history of a case which had been treated by means of his apparatus. When first attacked with the disease, the child was three and a half years old. He had been under observation at the Forty-second Street Hospital, where the diagnosis of hip-joint disease was made. He then passed to Dr. C. F. Taylor's Institute, where the diagnosis of Pott's disease of the spine was made and a brace adjusted. He was subsequently referred to a surgeon who took him in charge, using the same apparatus during nine months without improvement. He wore this instrument *newly* four years, constantly growing worse. He was then removed to Binghamton, where Dr. Burr applied a plaster-of-Paris jacket. It was worn five months, and the boy improved somewhat; but, as it became painful and caused an ulcer over the seat of lesion, it was removed, and the old brace readjusted. He again ran down, lost flesh, etc., and finally came under Dr. Wyeth's observation, in April, 1878. The disease was in the lumbar region, and there was also lateral curvature and partial paralysis of the lower extremities. A solid plaster-of-Paris jacket was applied with the belief that a cure could certainly be effected in that way, and the child was sent home. For the first two or three weeks there was some improvement, but after that the jacket became loose, and it was very evident that it was a failure. It was removed, and a new jacket was applied in the same manner. That one was worn a few weeks, and finally became as unserviceable as did the first.

He then put into use the apparatus exhibited and described above. In three months and a half the apparatus was removed, and the patient was cured. The gradual and continuous extension had overcome the deformity.

The conclusions arrived at by Dr. Wyeth were as follows:

First.—That inflammation of the inter-vertebral substance or caries of the vertebra was amenable to the same treatment as was the same lesion occurring in the ankle, hip, or other joints, and that continuous extension, regulated to suit the requirements in each case, in the one as in the other, enforced fixation and rest, and thus met the great indications more fully than other methods.

Second.—That Darrach's wheel-crutch, and certain other forms of apparatus, acting upon the same principle—creditable to the inventive genius in a former age—had served their respective careers of usefulness, and had been superseded by better methods.

Third.—Among modern instruments, the apparatus originally devised by Dr. C. F. Taylor had justly occupied a prominent position, but since *extension*, *fixation*, and *rest* were the indications in every stage of the disease, it did not enforce those indications as well as did the solid plaster-of-Paris jacket or the double jacket with continuous extension. It pressed upon the seat of lesion, and, by pressing upon a comparatively small portion of the body, it was very liable to set up local irritation at the points where pressure was made.

Fourth.—The solid plaster-of-Paris jacket was one of the most creditable innovations of modern surgery

for the treatment of caries of the vertebrae, the introduction of which has placed the medical profession and humanity under lasting obligations to Dr. Joseph Bryan and Prof. Lewis A. Sayre. But it was objectionable:

1. Because it required suspension of the patient, which involved more or less of annoyance and pain, and required a complicated apparatus.

2. It did not secure continuous extension.

3. It did not hold the extension obtained by suspension before the application, because it became loose, thus allowing the upper portion of the body to telescope down upon the lower, defeating the object for which it was originally employed.

4. It involved pressure upon the seat of the disease, interfering more or less with the reparative process, and caused unnecessary trouble in the management of whatever ulceration might exist.

Lastly, foreign bodies were liable to lodge beneath the jacket and necessitate its removal and readjustment.

The "Double plaster-of-Paris Jacket, with Extension Bars," heretofore described, he believed obviated those difficulties, since (a) it could be applied without suspension; (b) it involved pressure alone upon the sound structures, leaving the circulation free and unimpaired at the seat of lesion, where active repair was needed; it allowed ready access to ulcerating surfaces when these existed; (c) foreign bodies could be removed without removing the dressing; (d) by means of the *extension bars*, the *extension* and *fixation* could be daily regulated with mathematical precision, and could be constantly maintained without changing the dressing, no matter how much the jackets themselves might stretch or the tissues atrophy; and he held that that *continuous extension* not only tended to cure the disease more rapidly, but at the same time, while the diseased structures were soft and yielding, it would correct the *deformity* more thoroughly than any other method.

[Dr. Wyeth expressed his obligations to Dr. G. D. Burr for the assistance he had rendered in the management of the case, and credited him with the suggestion of perforating the zinc plates to make them more secure.]

The paper being before the Society for discussion,

DR. FRANK H. HAMILTON remarked that it was just one hundred years since Peveral Pott threw the first light upon the pathology of the malady in question, and explained satisfactorily certain peculiarities by which it was characterized.

At that time he reflected the views of surgeons with reference to treatment, and his plan was to place the patient in the recumbent posture and make an issue upon the back. Fortunately no child would submit to the latter without assuming the recumbent posture, and it was a question whether the posture or the issue brought about the results obtained. It had been reserved for English and American surgeons to advance a step beyond the now prevalent practice in Germany and Austria, and to discover that these cases could be treated successfully in the *erect* posture and with the patient walking about. Still holding to the view that fixation and rest were absolutely necessary to a successful issue of the case, American surgeons maintained that these could be secured while the patient was in the erect posture. Our apparatus had been so modified and improved that it permitted locomotion, and at the same time fixation and rest to the parts, thus enabling the patient to derive the benefit which came from physical exercise in the open air. Until now, the principle of extension had not entered into

our methods of treatment, and he was not prepared to accept the proposition of the author of the paper, even in the light of the remarkable case which had been reported. No other experimentation in that direction had been made, and he was therefore driven to resort to theoretical objections merely. The case reported was a remarkable one, and the cure creditable to the surgeon who had it in charge; but Dr. Hamilton was not prepared to accept it as a plan of treatment for caries of the spine. He could not recognize the exact parallel between these cases and cases of joint disease, in which it was usually believed that extension was useful. His objections to the apparatus, as described by Dr. Wyeth, were, first, anatomical. It was impractical, because extension of the spine could not be made and sustained. It was not possible to make permanent extension from the head. The attachment of the head to the atlas and the axis was by ligaments which were unaccustomed to extension; they had not been subjected to that kind of labor, and it was the experience of every man that no considerable amount of extension could be made upon those supports of the head without giving pain. Some of the ligaments had an insertion into the dura mater, and it was not possible for the patient to endure extension of the head sufficient to lift the upper part of the body from the lower part without suffering great pain, and he supposed it would cause death. The only seeming argument in favor of its practicability was found in the experience of orthopedic surgeons who employed apparatus receiving a variety of names, what Dr. Sayre had called a jury-mast, but which he preferred to call a head-rest.

Such apparatus was useful as a head-rest, but not as a means of extension.

He did not believe it was possible to make counter-extension—as opposed to extension from the hips—from the thorax; certainly not from the thorax as a skeleton. The thorax as a skeleton was cone-shaped, with the apex of the cone upward. That fact precluded the possibility of making counter-extension in that direction, unless the chest was expanded to its fullest capacity by a full inspiration and the apparatus was applied while the expansion was maintained.

But expiration must follow; and when it occurred, the apparatus would lose its hold upon the lower margin of the false and true ribs, and all counter-extension would be removed. When the expiration came, the chest collapsed and telescoped; it must inevitably telescope, and all counter-extension must cease. He thought it was equally impossible to make counter-extension from the lower margin of the ribs upward as it was to make it from the thorax denuded of its soft parts. But the apparatus was applied to the thorax covered by the soft parts, which apparently made the upper part of the chest the widest. Now it would seem practical to make counter-extension against the wide part of the thorax, where the resistance would be sufficient to make it effectual. But what caused the increase in the breadth of the chest at its upper part? It was mainly produced by the latissimus dorsi muscles. That could be more especially seen when the arms were raised; the direction of those muscles was changed so that they crossed the axillary space at a lower point, and it would seem that they might afford points of resistance from which counter-extension could be made. But the latissimus dorsi arose from the six lower dorsal vertebrae, the lumbar vertebrae, the sacrum, and the ilium. It arose so low down that if it was to be employed as a point of resistance, the counter-extension was practically made from the same point as the extension was made, namely, from the

hips. It certainly was not made from a point above the lesion, even if the lesion was in the middle of the lumbar region or at the junction of the dorsal with the lumbar region. It would not be difficult, also, to show that the pectoral muscles could not be used as points of resistance from which to make counter-extension. Indeed, all experienced surgeons had arrived at positively the same conclusions that the axilla afforded no point of resistance. Now, if all those points were rejected, what was there against which this apparatus could mount and find a point of resistance?

Dr. Hamilton also had a pathological objection, which perhaps was not so conclusive as was the anatomical objection to the apparatus described by Dr. Wyeth. The basis of the spinal lesion under consideration was inflammation, affecting primarily either the bodies of the vertebrae or their processes, or the articular surfaces, etc. The inflammation might have existed for many months in an obscure form before it was detected by the careful, diligent, and intelligent medical man. If the inflammation had been progressive, it could not exist without producing certain results; in short, there was what was commonly called swelling of the adjacent tissues, which was too painful to be employed as a point of resistance, and therefore offered a certain amount of impediment to continuous extension, were it desirable. He thought that extension was *not* desirable, but that fixation and rest were the most essential elements in the mechanical treatment. All forms of apparatus used by American and English surgeons were constructed with the view of obtaining fixation and rest, except occasional loose references had been made to extension. When speaking of extension, however, he had no reference to *erecting* the spine.

All the mechanics and surgeons had been successful, to a certain degree at least, in relieving the bodies of the vertebrae by throwing the body of the spinal column a little backward, and sustaining it in that position. He believed that straightening the spinal column in that manner had its value, but at the same time he thought it possible that its value had been overestimated as a means of cure.

What was accomplished by various kinds of apparatus was mainly fixation and rest. In other words, they acted as substitutes for muscles, and in that way gave the little patients relief.

The great comfort given to these little patients by Dr. Sayre's plaster-jacket came chiefly from the fact that it was a substitute for the muscles, and, when adjusted, the muscles no longer were made weary by continuous and prolonged action.

Thus far we had gone safely and surely, and as a means for fixation we had apparatus which had a certain amount of security. If Dr. Wyeth proposed to relieve the pressure by absolute extension for any considerable length of time, he did serious mischief to the patient.

Dr. Hamilton also maintained that none of the forms of apparatus used had straightened the spine *at the point of lesion*. The spine had been made more erect, the length of the patient perhaps increased by actual measurement, but it came from abolishing abnormal curves in the spinal column rather than from straightening the spine at the seat of the lesion. Reference was then made to a case faithfully and accurately reported in Dr. Sayre's work on Orthopedy, page 383, in which the claim was made that by means of a piece of lead rolled out in the form of a tape, it was demonstrated, with a positive mathematical certainty, that change had taken place in the curve of the spine after extension had been made.

Dr. Hamilton, thought, however, that if Dr. Sayre would carefully look at his own plate, he would at once discover that the angle of curvature at the seat of lesion was not changed, mathematically, a single line, but that the change was almost entirely in the lumbar region.

DR. SHAFER remarked that he preferred to employ some form of apparatus which was readily under his own control, and his choice was the antero-posterior support of Dr. Davis or Dr. C. F. Taylor. At the time he read his paper before the Society, in June, 1878, [see MEDICAL RECORD, Aug. 31, 1878] he spoke of a combination method. Since that time he had employed it with satisfactory results. A number of photographs were exhibited. He believed that the change which occurred in the spine in consequence of suspension or extension was not in the pathological curve, but in the compensatory curves. He also believed, although Langenbeck administered an anæsthetic before applying suspension in order to actually reduce the curvature, that it was a dangerous proceeding.

DR. GIBNEY gave the record of his observations in 106 cases treated at the Forty-second St. Hospital during the past three years. The observation with reference to the curve had been made by means of the malleable lead while the patient was placed in the prone position and no extension made.

In 92 cases there was no increase whatever in the angle of curvature. In 14 cases there was an increase, varying from one-eighth to one-half inch.

In 68 cases the lesion was in the dorsal region alone, in 11 cases in the lumbar region alone, and in 25 cases in the dorso-lumbar region.

The statistics were reported with the view of proving by facts that there was an apparatus in use which practically met the indications in the treatment of caries of the vertebrae. The apparatus consisted of two steel supports—one fitting around the body under the axillæ, the other fitting closely about the pelvis just above the trochanters—which were joined by four upright bars. Shoulder-straps were used to hold the body in an erect posture; and with the apparatus properly fitted, Dr. Gibney was at a loss to see how any increase of the prominence of the knuckle in the spine could take place. The deformity, however, was not overcome.

Dr. Gibney was not able to understand how permanent extension of the spinal column could be maintained, especially at the seat of the disease; but if the apparatus exhibited by Dr. Wyeth could sustain fixation, it was a valuable device.

DR. YALE remarked that every one who had had to deal with Pott's disease should receive with favor any apparatus which was able to ameliorate any of the severe symptoms; but he did not feel sure that an advance had been made in that direction by Dr. Wyeth, for the following reasons:

He did not regard the statement that "continuous extension in Pott's disease (in itself a joint affection) is as essential as in the treatment of the diseases of the knee, hip, or other joints," as a sound one. The joints in the vertebral column lacked very many of the elements which entered into the formation of a composite joint. There was less joint than existed at the sacro-iliac junction, or at the symphysis pubis, and yet extension in the proper treatment of disease affecting those articulations was not regarded as necessary. In his opinion, the only reason for resorting to traction or extension was to assist incomplete methods of fixation and prevent attrition of the joint-surfaces, which gave rise to very great suffering. It was a clinical fact that such attrition was not likely

to occur in caries of the vertebrae. In the spinal trouble there were no such nocturnal spasms as occurred in connection with hip-joint disease. He regarded it as utterly impossible to make extension of the spinal column, and thought fixation was the chief element in successful treatment of caries of the spine.

Again, he did not regard the statement that "the plaster-of-Paris jacket, as now used, and all other methods fail to meet the indications for the cure of the deformity with the cure of the disease, and often fail to cure the disease," as a valid objection to any plan of treatment.

He had had the good fortune to cure a patient by means of the plaster-of-Paris jacket, and all evidence of kyphosis absolutely disappeared. After six months there were no more symptoms of suffering. Nor could he regard it as a fatal objection to any method of treatment because it sometimes failed to cure the disease. When it was recollected what caries in any part of the body was, and how formidable a disease it became in an ill-conditioned patient, he doubted if any apparatus could be invented which would insure a cure in every instance. A certain percentage of these cases would always prove too great for our surgical skill.

Dr. Post was unable to understand how the comparatively small amount of moisture which escaped from the skin could soften that which, previously applied in a very moist state, had become hard, like plaster-of-Paris.

DR. WYETH, in answer to Dr. Post, said he could not state positively that it was absorption of bodily moisture that caused the relaxation of the grip of the plaster jacket, but he could state positively that it did become loose from some cause, and *continuous extension* would remedy this fault.

DR. JUDSON referred to an apparatus devised by Dr. Andrews, of Chicago, for the treatment of spinal curvature by extension. The extension was made by adhesive plaster.

DR. WYETH remarked, in conclusion, that it was scarcely possible to found a dynasty with one subject, nor could he hope to establish a new principle in surgery upon a single success. Experience alone would determine its efficacy. Should *extension* be impossible or improper, as the distinguished gentlemen who had discussed the paper argued (but which he still believed to be both proper and possible), upon one point all agreed, namely, that *fixation* was essential to success. Accepting that only, he held that the "double jacket," pressing equally upon all of the sound tissues, from which alone fixation should be secured, leaving the diseased structures unmolested, was more capable, by reason of the continuous extension it gave, of sustaining the amount of *fixation* necessary to success than any other method which had been devised.

METRIC SYSTEM.

DR. M. D. MANN read a preliminary report of the commission on the metric system.

The Society then adjourned.

THE PREVENTION OF THE ADULTERATION OF WINE IN FRANCE.—A chemical laboratory has been established in the Prefecture of Police in Paris, in which the wine, liquors, beer, and all other drinks brought into the city will be subjected to a chemical examination. This measure was rendered necessary by the increase in the quantity of adulterated articles sold.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Jan. 16, 1879.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

VALEDICTORY ADDRESS BY DR. PURPLE.

DR. PURPLE proceeded to deliver his valedictory address and to transfer the duties of his office to the President-elect, DR. FORDYCE BARKER. The address was plain, vigorous, and practical, and contained suggestions upon the following topics:

First—With regard to the meetings of the Academy. It was evident that the discussion of papers had, in the main, proved unsatisfactory. The plan, therefore, suggested by his predecessor, Dr. Flint, that discussion of papers should be postponed for one week after they were read, Dr. Purple believed would be a step in the right direction. He thought the tendency of such a plan would be to draw to the meetings of the Academy the Fellows who were pursuing special investigation, and would give to the Academy a class of papers which at present were confined to small societies with limited membership and feeble vitality.

Second—With regard to Fellowship, initiation fee, and annual dues. Dr. Purple thought the initiation fee far too small, when the benefits given to the Fellows were fully considered. He recommended that it be raised to twenty dollars. He also recommended that provision be made for compounding the annual dues. Reference was also made to the changes which death had produced in the Fellowship, and the names of the deceased Fellows were read.

Third—With regard to the library, its growth, and its usefulness. Within the past two years it had been thrown open for free use by the profession and the public. No public library in this country, with limited money resources, had grown like that of the New York Academy of Medicine. He recommended that a circulating department be at once established.

Fourth—With regard to the necessity of a closer union in the community of Fellowship and the resources of the medical profession.

Passing from these points Dr. Purple referred to the necessity of taking active measures for the liquidation of the mortgage upon the property of the Academy, and also the great need of more extended accommodations for the library and the general meetings of the profession.

With regard to the second measure, he was authorized to say that a pledge of \$5,000 had been given by a private citizen, providing the remaining \$2,000 of the estimated amount necessary to complete the proposed enlargement of the building was raised by the Academy.

Thanking the Fellows for the uniform courtesy which had been extended to him during the two terms in which he had served as their presiding officer, Dr. Purple introduced as President of the New York Academy of Medicine, Dr. Fordyce Barker.

INAUGURAL ADDRESS BY DR. BARKER.

DR. BARKER then delivered his inaugural address, of which the following is a brief abstract:

After thanking the Fellows for the great honor which they had conferred upon him, he remarked that it was thirty-two years since all the best men of our profession in this city, as he had been informed, united in organizing the New York Academy of Medicine. The necessity for such an organization was apparent, and good men and true co-operated to accomplish the result. The aim was not the mere culture of a special

department, but was broad in its scope, taking in the whole domain of our professional work.

Inquiry was then made as to how far it had been successful in accomplishing its mission, as to what it had done for its members, what it had added to literature and science, and what influence it had exerted on the profession and the public.

Dr. Barker here made brief reference to the ethical relations of the members of the profession to society, its standing in public estimation, its work either in the direction of medical societies or in the way of contributions to literature and science since the organization of the Academy, and which he believed were in a great measure due to the influence of the Academy.

Thirty-two years ago there was no public medical society in this city whose proceedings were reported, or which added to the common stock of the scientific literature of the profession. The Medical Society of the County of New York was dragging on a bare organic existence, but did no scientific work, and had but slight influence on the ethical condition of the profession.

The Pathological Society was but just commencing its useful career; long might it continue its noble work as an efficient contributor of positive knowledge, and as the teacher of young and old in a most important branch of our science.

Within the last thirty-two years the Medical Society of the County of New York had become an important, useful, and active working body, and had brought out many valuable and scientific papers which had been well and ably discussed before large professional audiences. In addition to its scientific work it had, by the laws of the State, important ethical duties in protecting the community from dangerous and irrepressible pretenders as medical practitioners, and also in preserving the professional morals of all regular and authorized practitioners. Some had had the opportunity of learning, during the past year, how faithfully it attended to its duties, and how sharply it looked for any errors in conduct whether committed wilfully or through thoughtless inadvertence. As most, if not all, the Fellows were members of that Society, the Academy, as a body, could but feel a great interest in its work and regard it as well worthy of confidence and support, and it must be deemed a misfortune to the profession and to science if it was not kept up to its present high standard of excellence. He who would attempt to elevate the one by depreciating the other was a common enemy alike to the Academy, to the County Medical Society, and to the profession of the city.

There were many other societies which were devoted to the cultivation of special departments of medicine, and which were accomplishing much in their spheres by inciting men to work. The assertion, however, was ventured for the candid consideration of all honest and disinterested minds, whether much of that work might not be done much more profitably and effectually in the appropriate sections of the Academy, and in that way the aggregated results would be brought out more prominently for the benefit of the whole profession.

The scientific work which the Academy had done was much more than generally supposed. The aggregate of the printed matter was over five thousand octavo pages. Some of the papers which had been read before the Academy must still rank as the best upon the subject. The discussions had been able, and many of them possessed remarkable merit.

Special mention was made of the discussion upon puerperal fever, the inciting cause of one upon the

same subject in the Academy of Medicine of Paris, which was continued more than a year.

Where could be found in the medical literature in any language a more thorough, able, and exhaustive discussion of albuminuria in all its bearings and relations than appeared in the publications of the New York Academy of Medicine?

Dr. Barker then passed to the consideration of the powerful influence which the Academy had exerted upon the profession outside of its scientific work, its papers and its discussions. "Again, as men talk one with another, new modes are discovered of looking at old things, prejudices fade away, and identity of fact and of meaning are found to underlie differences in words, and by comparing their observations and their conclusions with those of others, they correct the former and rectify the latter."

Few, perhaps, had noticed how many works had been published by Fellows of the Academy, and mention was made of those which came to memory: Treatise upon Physiology, by two of the members; the most advanced, original, and complete which have ever appeared in the English language; a large work on The Practice of Medicine; numerous special works, as: On Fevers; On Diseases of the Lungs; On Physical Diagnosis; On Diseases of the Nervous System; On Diseases of Women; On Diseases of Children; On Materia Medica and Therapeutics; On Ovarian Tumors; On Midwifery; On the Puerperal Diseases; works on General Surgery, by two of the members; On Military Surgery; On Uterine Surgery; On Fractures and Dislocations; On Diseases of the Genito-Urinary Organs; On Stricture; On the Venereal Diseases; On Diseases of the Bones; On Diseases of the Ear; On Orthopedy; On Pott's Disease; On Dermatology; On the Medical and Surgical Uses of Electricity, etc., etc.

Dr. Barker believed the assertion was true that the physician whose library consisted exclusively of all the works by Fellows of the Academy, had a better and more useful working library than belonged to a large majority of the profession in this country thirty-two years ago.

But it should be the aim of the Academy to aid the profession in acquiring a higher culture and such superior erudition as could only be attained by access to the literature of the past. For that purpose an earnest effort had been made to gather a library which, at the present time, contained more than 9,000 volumes. In one respect it surpassed all others—namely, that it had the most complete set of all the medical journals which had been published in this country. The remarkable success in gathering the library had been very largely due to the persistent energy of the outgoing President. At the least estimate, \$10,000 could not have bought the volumes which he had given to the library.

It was a matter of congratulation that the financial condition of the Academy was so excellent, and that its receipts were considerably in excess of its expenditures.

Dr. Barker then passed to the consideration of the work of the stated meetings.

Most of the organic work of the Academy was done by committees and the Council. Hence no cheap notoriety could now be gained by frivolous speeches on such matters by those who, from incompetence or from a just self-appreciation, fortunately never took part in the scientific discussions. Good papers and good discussions were sure to call out full meetings.

It was to be regretted that some of the prominent men in the profession who formerly attended the

meetings of the Academy, read papers, and took part in the discussions, were now seldom seen there. It might be that the flight of time had worn out the professional ardor of their youth, or blunted the sense of duty to the profession, and that they had arrived at that happy consummation when they had no more to learn, with no desire to add to their knowledge or correct the errors of others. They had probably settled down in a placid contentment, with abundant means, a good practice, and a conceded position. But if the good hearts and sound principles of such could be aroused to action, they would cheer and encourage by their presence, and if they took no part in the work they would still be useful members by being ornamental.

Delicate allusion was made to another fact. A *very* few, he was happy to say, of the conspicuous members had deserted the standard, and had resigned the Fellowship of the Academy. Such action, he believed, resulted either from misconception or misinformation, or bad logic or bad judgment. He would not say that the Academy could better afford to do without them than they could afford to keep aloof from the Academy, but he would say that it was to be hoped that some of them would in the future retrace their steps. He thought he could venture to say for such, "still the lamp holds out to burn," [he would not complete the couplet] and that they would be warmly welcomed back, as they would doubtless bring forth fruit meet for repentance by good scientific work, and by liberal contributions to the library and to the treasury.

Those who warmly sympathized with the aims of the Academy, and who would zealously co-operate in its good work, were welcomed. "From malcontents, croakers, and pessimists, good Lord deliver us."

With reference to papers it was to be hoped that those best qualified by special study and experience to discuss them would make due preparation, in carefully maturing their ideas, and thus secure a facility in clear and lucid expression. The Academy wanted no crude, ill-considered statement of fact, no frivolous effervescence of the moment. It would humanely spare all from making a pitiable, even though it was a ludicrous exhibition of folly and ignorance. The meetings of the Academy could not become the arena for the display of garrulous imbecility, pretentious assumption, or, to borrow a phrase from Dr. O. W. Holmes, "the flippancy of half-knowledge."

Reference was then made to the volume of Transactions and the possibility of making it pay the expense of its publication.

The zealous co-workers, the Medical Journal Association of the City of New York, were some years in advance of the Academy in a successful effort to furnish for their members access to all the current medical literature in the department of medical journals and monographs. Their effort was one worthy of all commendation, and its usefulness to themselves could not be too highly estimated.

Dr. Barker believed he expressed the hope and the wish of the Academy, that its walls might be soon extended, so that it might, at no distant day, give house-room for all accumulations of that character "without money and without price;" that the Hall of the Academy should always be open to the profession from all parts of the State and the country, in which they would be hospitably welcomed, and in which they would be sure to find every medical work, every medical journal in all languages, every essay, and every paper known in medical literature. Might he not feel assured that all the Fellows of the Acade-

my would heartily co-operate with him in every effort to bring about that result as speedily as possible.

After the address \$800 were secured by voluntary subscription towards the two thousand dollars desired for building purposes.

The President announced that Dr. T. Gaillard Thomas would read a paper at the next Stated Meeting.

The Academy then adjourned.

Special Meeting, January 30, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

A NEW METHOD OF REMOVING SUBMUCOUS AND INTERSTITIAL FIBROIDS OF THE UTERUS.

DR. T. GAILLARD THOMAS read an interesting paper upon the above subject. It was limited to the consideration of surgical procedures most applicable to the removal of interstitial and submucous fibroids.

The key-note to the modern advance in this subject was struck by Dr. W. S. Atlee, who, in 1853, presented an essay to the American Medical Association "On the surgical treatment of certain fibroids heretofore considered beyond the resources of our art." Both in Europe and in this country the lead of that bold surgeon had been followed, and his method had come to be recognized as legitimate surgical resources.

Dr. Atlee's views could be embraced under three propositions:

1. If a non-pediculated tumor could not, from the nature of its attachment and envelopes, be expelled or drawn by mechanical means through a dilated os uteri, it was advisable to make by the knife a means of escape for it into the uterine cavity, through its capsule or enveloping tissues.

2. If the tumor thus offered an outlet could not be removed, it should be forced into and out of the uterine cavity by the persistent use of ergot and cutting the cervix.

3. The tumor, once coming within reach, it should as soon as practicable be enucleated and removed by the surgeon.

That that method of treating such cases was attended by the great dangers of septicæmia, peritonitis, hemorrhage and exhaustion, was not to be denied. But a policy of watching, waiting, and inactivity was by no means always a safe one.

Interference, however, should not be practised unless impending danger urged a resort to it.

Removal of these tumors by strangulation was a method which at the present time every cautious surgeon was averse to.

The plans now usually adopted could be summarized as follows:

Excision, torsion, avulsion, crasement, enucleation, and the production of sloughing. To all those, serious objections attached. Aside from certain difficulties attending its performance, *excision* was often impracticable. Torsion could be applied only to pediculated tumors. *Avulsion* and *enucleation* were difficult of accomplishment and slow of performance, and the patient was in danger of sinking in consequence of exhaustion. *Ecrasement* frequently failed to remove the entire growth, and left the uterine attachment to decompose and cause septicæmia. Removal by the process of *sloughing* insured so certainly septicæmia that it should be regarded as unwarrantable.

One of the great objections to the use of *ergot* was its tendency to impair nutrition, and produce death and consequent decomposition of the neoplasm. The

object of the paper was to offer a plan which experience had led him to regard as superior to any yet adopted, and which he believed would supersede them with all who were willing to give it a trial.

The method consisted in seizing the most dependent and accessible part of the tumor with a strong vulsellum forceps, passing along its sides the *serrated scoop, or spoon-saw*, and by a gentle pendulum motion from side to side, sawing through the attachments of the tumor and forcing it entirely from its connection with the uterus.

The advantages claimed for the instrument were the following:

1. The attachments were separated by a saw which greatly limited hemorrhage.

2. The shape of the spoon, convex without and concave within, caused it to follow of itself the contour of the tumor, and at the same time protect the uterine tissue.

3. The highest attachment could be as readily reached as the lowest.

4. The saw action secured separation with rapidity and with certainty.

5. The spoon-saw secured separation of the growth at its highest point of attachment, and left no peduncle to decompose.

To illustrate the advantages which the new method possessed over the old methods, a number of cases were first reported, and then followed by the report of a number of similar cases operated upon by the method just described.

CASE I.—Large fibroid expelled through an opening made in its capsule. An artificial os was made, and the tumor left to be delivered by uterine expulsion. Decomposition occurred; the process of delivery was tedious, but the patient finally recovered.

CASE II.—Ergot treatment. Presenting part of the tumor became offensive and gangrenous. The patient suffered markedly from exhaustion and septicæmia. A portion of the tumor was subsequently removed by the *écraseur*, a part by enucleation, but it was only with the greatest difficulty that the uterus was emptied. The tumor was about the size of a coconut.

Dr. Thomas was confident that, by means of the spoon-saw, he would have been able to accomplish in ten minutes what required an hour by the method employed.

CASE III.—Submucous fibroid enucleated during the process of septic fever. Recovery.

CASE IV.—Small tumor; weight, four ounces; shock great; hemorrhage trifling; enucleation; operation for its removal occupied one hour. He was confident that with the spoon-saw the operation could have been performed in eight or ten minutes, and that the shock would have been much less.

Cases to the number of seven were reported. In the last three the growth was not entirely removed by the operation; but Dr. Thomas's firm conviction was that, if he had to deal with these cases now, he would be able to completely remove the tumor in each case.

The cases reported were not selected because they illustrated difficulties, but they were really only average cases in that respect.

Six cases were then reported in which the tumors were removed by means of the spoon-saw.

METHOD OF DETERMINING THE EXTENT OF THE ATTACHMENT OF THE TUMOR.

Before relating their histories, a description was given of a new instrument, and a new method of determining the extent and situation of the attachment which the tumor had to the uterine wall. After try-

ing various methods, he had fixed upon the use of the flat *whalebone sound*.

In order to ascertain the outline of the tumor and the extent of its attachment, the index finger of the left hand was placed against its most accessible part, then the sound was passed up along the side of the tumor until it became arrested. The sound being then withdrawn and the finger kept upon it, it was laid upon a sheet of paper, and being curved, a line was drawn from its tip to the indicating finger. The same was done upon the opposite side of the tumor, and in that way an approximate and wonderfully exact idea could be obtained with reference to the situation and extent of the attachment.

CASE I. The attachment occupied one entire side of the uterus to within an inch of the internal os. The patient was etherized, placed in Sims's position, and his speculum was introduced. The spoon-saw was used and the attachment separated in a few minutes. By other methods certainly half an hour would have been required to perform the operation. The tumor weighed seven ounces and a half. The patient made a good recovery.

CASE II. was one in which he assisted Dr. A. C. Post at the Presbyterian Hospital. The tumor weighed seventeen ounces, was attached about three-eighths of its circumference, and the separation was completed in forty minutes. The patient made a good recovery.

CASE V. was one in which Dr. Thomas thought the separation of the attachment could not have been made with any other instrument without opening the peritoneum. The tumor weighed eight ounces, was interstitial, and well-nigh filled the pelvic cavity.

CASE VI. was one in which the tumor could have been removed easily by some of the ordinary methods, but by the method employed its removal was made much easier.

Dr. Thomas was so sanguine and thoroughly convinced by his experience, that he unhesitatingly recommended that the use of the spoon-saw should supersede all other methods in the removal of submucous and interstitial uterine fibroids. He would say that, in any case in which the vulsellum forceps could be fixed in a fibrous tumor of a size sufficiently small to admit of its delivery by the vagina, detachment of it from the uterus could always be accomplished by this method. The accident of cutting into the peritoneum was less likely to occur than when enucleation was employed.

DELIVERY OF LARGE TUMORS FROM THE VAGINA, AFTER THEIR EXPULSION FROM THE UTERUS.

Any tumor which could be completely accommodated in the pelvis could be delivered without diminution in bulk; but sometimes a projecting part of the tumor might fill the pelvis completely, and still a larger portion might remain above the superior strait, which could not be drawn through without mutilation. Under such circumstances, he recommended the following methods of delivery:

1. Seize the tumor with strong forceps, draw it down, sever the distended perineum to the sphincter ani, partially or completely invert the uterus, detach the tumor by the spoon-saw, replace the uterus at once, and close the perineum by sutures.

2. Successive sections of the tumor might be cut away by means of the galvano-cautery wire.

3. A large trocar and canula, or the actual cautery, or the trephine obstetric perforator, might be used to channel up the middle of the tumor, and then, with a strong pair of scissors or osteotome, pieces could

be cut out, and the tumor so diminished in size that it was susceptible of delivery.

That either of those ways was better than enucleation or the production of sloughing, he had not the slightest doubt, from his own observation and experience.

The paper being before the Academy for discussion,

Dr. A. C. Post remarked that in the case referred to by Dr. Thomas, in which the operation was performed at the Presbyterian Hospital, he found much advantage to arise from passing a strong ligature through the projecting part of the tumor, thus giving him a more powerful means for making traction than by the use of the vulsellum forceps alone.

He believed it would have been impossible to detach the upper part of the tumor without the use of the serrated spoon. The instrument worked smoothly and pleasantly, and when the tumor was entirely detached an effort was made to extract it through the cervix uteri, but he was not able to withdraw it in that manner. He then made a series of radiating incisions in the tumor, and it was removed without further difficulty. For a number of days the uterus remained exceedingly soft, like a piece of wet buckskin. There was considerable hemorrhage at first, but it was easily controlled. There was no bleeding subsequently, and at the end of two months the patient's health seemed perfectly restored.

Dr. T. ADAMS EMMET remarked that he had had no personal experience in the use of the instrument especially recommended, but he was pleased with the report made by Dr. Thomas, for he knew of no other means of operating by which such good results could be obtained. He was satisfied, from the shape of the instrument, that it was far superior to the *céraseur*, which he had not used in any case of the kind for many years. Without the report of the cases by Dr. Thomas he should have raised an objection to the use of the instrument—the same objection which he had against enucleation, and that was the danger of blood-poisoning from leaving so large a cavity with a surface favorable for absorption. But there were many cases in which that risk must be taken. The tumor might be so large that the uterine wall had not sufficient strength to drive it into the vagina, and an operation became necessary, and operative procedure also became necessary for the removal of very small tumors.

Some ten or eleven years ago he employed an instrument something like the one presented by Dr. Thomas. It consisted of an iron finger-nail, as it were, a shell which was slipped over the finger, and he found it to work very satisfactorily in sawing out the tumor. The only objection to it was the fact that the finger soon became tired, and for that reason its use was abandoned.

About the year 1865 he operated for the removal of a fibroid which was attached to the fundus of the uterus. The tumor was drawn down, the *céraseur* applied, and he was quite certain that it was removed close to the junction. The patient, soon after the operation, began to show symptoms of blood-poisoning, and finally died. At post-mortem he obtained a lesson which he had ever since remembered. It was found that a large portion of the tumor had been left in the uterine wall, and the explanation was that the traction had pedunculated the tumor, so that when removed by the chain the cut was made at some distance from the uterine junction. Since that time he had followed the rule, as far as possible, to wait until the tumor had been driven into the vagina. As soon as the tumor reached the vagina we had a guaranty

that there was sufficient uterine tissue to drive it down, and then it could be removed piece by piece without injury to the uterine cavity. An attempt to deliver by traction might be made, thus bringing on labor-pains and imitating Nature.

But there were cases in which such a plan of treatment could not be adopted, and there was no other resort except the plan recommended by Dr. Thomas. Certainly the old plan of enucleation had been attended with the greatest danger in cases of large tumors. He believed, therefore, that the plan given by Dr. Thomas was a valuable one for the removal of *large* tumors and *very small* tumors.

With reference to the removal of large tumors which had been driven into the vagina, he did not recommend dividing the perineum or entering the uterine canal at all. The fact that the tumor was in the vagina was evidence that there was sufficient uterine tissue to drive it out, and as soon as it was cut loose it could be readily removed and the result was always good. The only time we were obliged to enter the uterus was when the pedicle was divided, and the pedicle was always attached at the lower portion of the uterine wall. He had in that manner removed several tumors weighing between seven and ten pounds, and the operation was attended by less risk than when the uterine cavity was invaded.

He should employ the instrument devised by Dr. Thomas, anticipating good results from its use.

DR. A. J. C. SKENE, an invited guest, remarked that he had operated once in the manner recommended, and in a case which he thought tested the capacity of the instrument fully as much as did any of the cases reported by Dr. Thomas. It was an interstitial fibroid occupying the anterior wall of the uterus. Eight years ago the tumor projected far enough down to press upon and distend the perineum. Considerable blood had been lost. He resolved to remove as much of the tumor as possible, and the operation was performed by means of the galvano-cautery. The operation controlled the hemorrhage for a time, but the tumor returned. The patient passed from under his observation, and he supposed that she was dead. This winter she reappeared, and he found her in such an exceedingly anæmic condition that he despaired of saving her life. The tumor projected so far down that he was unable to reach the os uteri. He was unable to control the hemorrhage by ergot; he could not use the tampon. All other means failed, and operative procedure afforded the only chance for saving the patient's life. He feared that his patient would die before the operation could be completed. To avoid hemorrhage as much as possible, the capsule of the tumor was divided by the thermo-cautery. He then used the serrated spoon, and being unaccustomed to its use, half an hour was consumed in the operation. The tumor was easily removed, notwithstanding the cicatricial tissue resulting from the former operation; there was no hemorrhage, and the patient made a good recovery. After removal of the tumor, the finger was introduced and the fact ascertained that he had passed closer to the peritoneum than he wished to go again. The cicatricial tissue and the anæmic condition of the patient submitted the operation to a severe test, yet the result was eminently satisfactory.

DR. BOZEMAN thought that by the use of the instrument presented by Dr. Thomas a more effectual removal of the tumor could be made than by means of the process of enucleation or any other method. In that respect great advantage doubtless would follow its use, because of the avoidance of the liability to blood-poisoning.

DR. LAWRENCE JOHNSON referred to the satisfactory result obtained in the case which Dr. Thomas saw with him, and had included among those which he had reported.

DR. H. T. HANKS asked Dr. Thomas if he would perform the operation in a case in which the pelvic cavity was filled with a uterine fibroid and a fetus existed above it at full term of utero-gestation.

THE PRESIDENT said that he wished to call forth from the author of the paper remarks which seemed necessary with reference to certain points, in order to make the discussion as complete and valuable as it should be to the profession at large. Such operations, performed by experts, might be perfectly safe; while, in the hands of our compeers who failed either from lack of the same knowledge, or from the lack of manual dexterity, or from the lack of prudence and caution, they might result as disastrously as from erroneous judgment with reference to the propriety or the mode of performance.

It was well known that a certain class of uterine fibroid tumors disappeared either spontaneously or under the influence of medical treatment. It had fallen to his lot in several instances to see fibroid tumors of the uterus of very large size disappear.

In one case, which was also seen by the author of the paper, the tumor was extremely large, the abdominal and the pelvic cavities were filled by the growth, the woman became pregnant and went to the full term of utero-gestation twice, severe hemorrhage occurred repeatedly, and yet the tumor had entirely disappeared, and the woman had been restored to good health.

He also referred to a case which came under his observation in Brooklyn twenty-five years ago. In that instance the patient nearly lost her life several times from hemorrhage produced by the uterine fibroid, but the tumor finally disappeared, apparently spontaneously, and the woman was restored to health.

We were aware, also, that a certain degree of success had been attained in the treatment of uterine fibroids by the use of ergot, hypodermically or otherwise. He made the remarks with the special view of calling out a statement with reference to the indications for the operation recommended.

DR. THOMAS, in closing the discussion, first referred to a case which gave answer to the question asked by Dr. Hanks. He was called in consultation to see a case in which a uterine fibroid was so attached that it gave space for the development of a fetus, and yet was so large as to almost completely fill the pelvis. Every legitimate effort was made to effect delivery of the child by the natural passages, but it was found impossible. The head was almost entirely above reach. It was regarded as almost absolutely certain that craniotomy would result in the death of the mother as well as the child, and resort was made to Cæsarean section.

Under such circumstances he would *now* proceed at once to remove the tumor by the method described, and then deliver the child. At the time he saw the case he did not know of the method, and there was no possibility of its removal by any of the old methods.

DR. BARKER had made allusion to the fact that fibroid tumors of the uterus sometimes disappeared either with or without treatment, and had asked that he should give his opinion with reference to the indications for the performance of the operation.

In answer, he referred to a statement made at the commencement of his paper, namely, that interference should not be practised in these cases unless impending danger urged resort to it.

It was his custom to state to medical students that the man who performed any operation for its removal simply because of the existence of a uterine fibroid, was absolutely culpable. In no case should interference be made unless impending danger required it.

For example, in such cases as those operated upon by Dr. Post and Dr. Skene, in which there was no probability or possibility of arresting the hemorrhage by the use of ergot or other means, he believed that we were called upon to interfere by operative procedure.

In the case which he saw with Dr. Barker, he thought the doctor would recollect that the tumor disappeared at the time of the menopause.

If the patient could be kept along until the menopause arrived, there was a prospect that the tumor would disappear. But suppose that the menopause was ten or fifteen years distant, the patient became anæmic from hemorrhages, the feet became swollen, etc.: a continuation of that condition certainly would end in death, and operative interference afforded the only chance for saving the patient's life.

In certain forms of pedunculated tumors almost any form of operation would answer an excellent purpose.

He would restrict the use of the spoon to such cases as those in which the attachment of the tumor was so great that it would not in all probability be naturally delivered—cases in which separation of the tumor and nothing else would accomplish that result. In such cases he recommended the operation and brought it forward as one to supersede all others, because it was readily performed and was a safe method of removing such tumors.

The Academy then adjourned.

Correspondence.

COOL ACIDULATED WATER IN CYSTITIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—By your kind indulgence I will occupy a corner in your valuable journal, by way of explanation:

In a previous number (January 11th) of the RECORD, Dr. C. H. von Tagen, of Chicago, Ill., criticises my letter published in the same journal for December 28, 1878, in (1) that I did not state the quantity of cider-vinegar used to the four ounces of water, and (2) asks the question "where" (1) "he obtained 'cold spring or branch water' at a temperature of 70° or 80° F? (was the water first warmed?)"

(1) Cider or apple-vinegar is not officinal, and as manufactured and used at the different houses in the country is of very variable strength, as fermentation was or was not complete. Some specimens have not half the strength of others; one may be too weak, the other too strong, without dilution, for pickling purposes. Of the former, one part to one of water; of the latter, one part to three or four of water, would not be too strong.

(2.) As there is no mark on the thermometric scale above which is cool and below "cold," the term "cold" was used relatively—*i.e.*, in the sense that anything coming in contact with the healthy body and producing the sensation of cold, is "cold," though I believe to temperatures above 60° or 70° F., and not warm nor hot, the term "cooler" is applied, and is, in my humble opinion, a very indefinite term

—cold, cool, warm and hot respectively running into each other by insensible gradations.

In preparing the injection in the last case (for I did not prepare that in the first) the temperature of the fluid, either before or after the vinegar was added, was not taken, consequently I could not know exactly how cold or cool (if preferred) it was, or I would not have used the term "about" in both cases before the figures indicating the degree of temperature. I knew the water at the spring, from which the first case was treated, to be *warmer?* (not so cold) than is usual for spring water, and estimated the temperature at about 60° or 65° F. If the water from the spring, before it was used, remained any considerable time in the house, at a temperature that prevails at that season (July), it would approach the temperature of the circumambient atmosphere, and the addition of the vinegar, which had stood for days in the house, would still further raise the temperature to probably 75° or 80° F. In the second case I *estimated* the water, used in the injection, at the spring at 53° F., which, by testing, I find to be the average temperature of the springs of the county. The water was fresh from the spring, and quite cold, but the vinegar was very weak, so I had to use as much of the latter—which was much warmer than the water, from long standing about the house—as of the former. The fluid thus compounded, I supposed, could not go above 70° F., so it was put at that figure. In making these estimates it was my intention rather to go above than below the actual temperature, fearing that I might understate it. In the first case treated the temperature of the fluid injected may have been as low or lower than 70° F.; it was certainly not above 80° F. I am confident the fluid injected in the second case was not above 70° F., and it may have been as low as 60° F. It was my intention, in this case, to use the water *as cold as I could get it* (ice not being obtainable), if, when compounded, the solution had been as low as 53° F., the temperature of the water at the spring.

With regard to the query in the last clause of Dr. von T.'s letter, if he will refer back to the first case treated he will find that I directed the cider-vinegar then because the urine was *ammoniacal*.

Respectfully,

W. H. BRAMBLETT, M.D.

NEWBORN, VA., January 20, 1879.

DR. MARION SIMS AND HIS OPERATIONS IN VIENNA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—When I read the article by my friend Prof. Fordyce Barker (with the above caption), in the RECORD of the 9th November last, I thought I would say nothing more on the subject.

But I changed my mind when, a few days ago, I received the December No. of the *Richmond and Louisville Medical Journal*, in which occurs the following paragraph: "A correspondent of the *Chicago Medical Journal* states that all the patients Dr. J. Marion Sims operated on while in Vienna died within ten days of peritonitis."

I went to Vienna for a special purpose, to remain a month or six weeks, but at the end of a fortnight I was telegraphed to go to London, and was obliged to leave before the object of my visit was accomplished.

While in Vienna I operated on three cases of epi-

thelioma of the cervix uteri; one for Prof. Spaeth, one for Prof. Boehm, and one for Prof. Salzer.

The first was an utterly hopeless case, which, nevertheless, progressed very well for five or six days, when she died of a sudden hemorrhage, the result of a slough between the uterine and peritoneal cavities. The second (Prof. Boehm's, in the Rudolph Hospital) was a very favorable case for operation. The amount of tissue removed was not larger than an English walnut. I fully expected her to get well, but she died of peritonitis in thirty-six hours.

The third (Prof. Salzer's) was a very unfavorable case. The epitheliomatous growth extended far up into the body of the uterus, destroyed the posterior portion of the cervix, and invaded the posterior wall of the vagina, extending down on it for two inches or more. When the vegetations were removed from the vagina the cervix was drawn forward with a tenaculum, and this movement tore the cervix loose from the posterior wall of the vagina, making an opening into the peritoneal cavity large enough to admit an egg. Blood passed freely into the peritoneal cavity; it was sponged out; the ruptured parts were brought together with four interrupted sutures. The operation was completed in the usual way, and the patient recovered without the least drawback.

This is a succinct account of the cancer cases. The first two ought to have recovered, but died. The last one ought to have died, but recovered.

My friends were anxious to see my method of operating, and of course I was obliged to operate on such cases as were presented to me. The only case favorable for successful operation was Prof. Boehm's, the one that died of peritonitis.

I performed but one operation for vesico-vaginal fistula in Vienna, and that was for Prof. Boehm, at the Rudolph Hospital. It was a very bad case, involving the cervix uteri with narrowing of the vagina from dense cicatricial tissue following extensive sloughing. The vagina was so contracted by fibrous bands that the index finger could not be passed through the contracted part to the cervix uteri. I divided the cicatricial bands, and introduced a vaginal dilator, and the next day I operated on the fistula, introducing seven or eight interrupted silver sutures, and the case was cured in a week.

The only other operation I performed in Vienna was amputation of the cervix uteri in a case of proclivita, for Dr. Rokitsansky, at the Marie Thérèse Hospital, covering over the stump with vaginal tissue secured with silver sutures.

In all these operations there was but little room for comparing methods between different operators. Dr. Bozeman never operated for cancer in Vienna. He operated only for vesico-vaginal fistula, an operation perfectly devoid of all danger; for, of the hundreds of operations of this sort performed by Dr. Emmet and myself at the Woman's Hospital and in private practice, I think there has never been a death. Therefore there can be no comparison instituted between these simple operations and those serious ones for cancer of the cervix uteri.

The only comparison I heard made in Vienna between my single operation for vesico-vaginal fistula, and Dr. B.'s numerous ones was this: that I took only hours instead of weeks to prepare a contracted vagina for operation; and that I took only thirty minutes to operate on a difficult case of vesico-vaginal fistula instead of three hours; and that the position of the patient for operation and the whole method of operating were in accordance with correct surgical principles, and void of pretension and mysticism.

Thanking my friend Prof. Fordyce Barker for his manly defence of me in my absence, and thanking you for the space you have kindly allowed me, I remain
Yours truly,

J. MARION SIMS.

THE ILLINOIS STATE BOARD OF HEALTH.—The State Board of Health has removed its central office from Chicago to Springfield, and Dr. Horace Wardner, of Cairo, has taken the place of Dr. Rauch as president.

NEW YORK ACADEMY OF MEDICINE.—At a Stated Meeting of the New York Academy of Medicine, held Jan. 16, 1879, the following preamble and resolutions were presented by Dr. Hubbard, in behalf of Dr. J. G. Adams, and unanimously adopted by the Academy, and ordered to be published in the N. Y. MEDICAL RECORD:

Whereas, Samuel S. Purple, M.D., to-night retires from the presidential chair of this Academy, which he has filled for four years with so much dignity and advantage; therefore,

Resolved, That the Fellows of this Academy have great pleasure in testifying to the great success of the administration of Dr. Purple, no less than to the dignified manner in which he has presided and watched over its interests. Under his auspices the Academy has attained to its present high position as a scientific body. More especially in the department of its library and reading-room, to which he has personally contributed so largely, and which have grown up under his fostering care, the Academy have reason to thank him for his distinguished and self-denying service.

Resolved, That the thanks of this Academy are hereby tendered to Dr. Purple, with the wish and hope that we may be still further aided by his efforts in this direction, in which he has shown himself so wise and faithful a counsellor.

Resolved, That these resolutions be published in the MEDICAL RECORD.

[Signed]

FORDYCE BARKER, *President*.
H. T. HANKS, *Secretary*.

PROF. VON LANGENBECK, of Berlin, recently celebrated his 68th birthday, and is still vigorous.

PROFESSOR HITZIG is soon to become a member of the faculty at Halle, and enter upon his duties as director of the lunatic asylum in that city.

JACOB MOLESCHOTT has been elected professor in the University of Rome, Italy.

PILOCARPINE IN HICCOUGH.—Dr. Ortille was successful with gmm. 0.025 muriate of pilocarpine in curing hiccough which had resisted every remedy.

The patient was 62 years old, and was suffering from symptoms of cerebral thrombosis. The singultus continued even while the patient was under the influence of morphia.

TREATMENT OF CRACKED NIPPLES.—Dr. Haussmann has found that lint, soaked in a two per cent. solution of carbolic acid, applied to the nipples, and wetted every two or three hours with the same, gives immediate relief to the pain, and causes complete healing (although the baby is still nursed from the nipples) in two to three days.

ASTIGMATISM.—A simple test therefor may be made by ruling an equal number of lines, of equal distances and equal thickness, vertically and horizontally, side by side. These lines should be looked at, the apparently more distinct fixed upon, and then the sheet should be turned 90°. The vertical lines will become horizontal, and it is a check against any inaccuracy in ruling if, with the changed position, the same result with regard to the then vertical and horizontal lines is noticed. This is recommended by M. Javal, the eminent physiologist.

RUSSIAN MEDICAL STUDENTS.—"Not only within the colleges and universities are they subjected to the arbitrary rules of this police system, of which all administration in Russia partakes, but outside in their private life they are kept under the strictest surveillance. Being almost all very poor, they herd together in miserable quarters, or occupy small chambers, destitute of every comfort, in the lowest parts of the city. In this state they are liable at all hours of the day and night to be broken in upon by the police, and to have their things turned upside down in the search for forbidden publications, or to be arrested without a moment's warning on suspicion."—*Correspondent in London Times*, January 1, 1879.

M. PAUL BERT, newly elected president of the *Société de Biologie* (Paris), in taking his seat pronounced a fine panegyric of M. Claude Bernard, his predecessor.

DEATH OF PROF. GRANDJEAN.—The **FACULTÉ DE NANCY** has sustained a heavy loss in the death of Professor Grandjean, professor of therapeutics.

NEUROSES OF THE HEART.—J. Milner Forthergill, discussing the neuroses of the heart, divides the anginous affections into neural angina and true angina pectoris. The former is oftenest seen in women at about the climacteric. It is not very dangerous, and is frequently relieved by arsenic. True angina is produced by spasm of the arterioles, which causes a rise of pressure within the heart, and is dangerous or not according to the condition of the heart. It occurs oftenest in men of gouty condition and may be relieved sometimes by iodide of potash.—*Brain*.

TETANUS AND CHLOROFORM.—From an analysis of 115 cases of tetanus, Dr. D. W. Yandell asserts that chloroform is the most efficient agent in its treatment, while calabar bean ranks among the least effective.—*Brain*.

OPTIC NEURITIS, by C. L. LUNDY.—In a small pamphlet the history of this disease is very well described, and illustrative cases added.

NITRITE OF AMYL IN INFANTILE CONVULSIONS.—In a case reported by Dr. Engel, this agent was successfully used. The parents had lost three children previously by epileptiform convulsions of the same character as those affecting the present case. The child, eighteen months old, has continued in convul-

sions for five hours, and was apparently moribund, when as a last resort five drops of the amyl were given along with $\frac{1}{4}$ gr. of morphia. The child at once went off into a quiet sleep.—*Phil. Medical Times*.

MEDICAL JOURNALS.—Fifty years ago there were eight medical journals in the United States. Now there are fifty-three of the regular school, nine homœopathic, and seven eclectic. In the last fifty years, 1630 regular journals and 214 homœopathic have been started. Thus about six per cent. of the former and four per cent. of the latter class have survived.

Great Britain and colonies have 36 journals; France 64; Germany, 96.—*Boston Med. and Surg. Journ.*

OBJECTIVE vs. SUBJECTIVE.—The science of the physician is above the assertions of the patient.—**RICORDI**.

INSUFFLATION POWDERS vs. NASAL DOUCHE.—Dr. H. G. Miller, of Providence, deprecates the use of the nasal douche, and insists all medications should be in the form of dry powder and used by insufflation.—*Proc. Rhode Island Med. Society*, Dec. 18, 1878.

STRAWBERRIES IN CHOLERA INFANTUM.—PROFESSOR STORER, of Harvard, says (*Boston Jour. Chemistry*) he was successful in curing a case of cholera infantum by having half of a strawberry given to the child every hour.

MILK DIET IN CYSTITIS.—The *Lancet* of Dec. 7, 1878, reports a case of chronic cystitis (occurring seven years after lithotripsy) as having been cured by an exclusively milk diet.

GRAAFIAN VESICLE DURING PREGNANCY.—Dr. Slaviansky reports (*Med. Centralzeitung*, Oct. 30, 1878) the case of a woman, æt. 24 years, who died in the third month of gestation, and the post-mortem showed ovarian follicles which were on the point of bursting, as well as recent corpora lutea. This confirms the opinion enunciated by the late Prof. Charles D. Meigs, that the development of the Graafian follicles continued during pregnancy.

THE CHAIR OF MATERIA MEDICA AT JEFFERSON MEDICAL COLLEGE.—We understand that Dr. J. Solis Cohen, Lecturer on Laryngoscopy and on Clinical Medicine in Jefferson Medical College, is a prominent candidate for the Chair of Materia Medica, left vacant by the death of the late J. B. Biddle, M.D. The other candidates mentioned are Dr. James C. Wilson, Physician to Jefferson Medical College Hospital, and son of Ellwood Wilson, M.D., the well-known gynecologist; Dr. W. W. Keen, Physician to St. Mary's Hospital; John J. Reese, M.D., Professor of Toxicology in the University of Pennsylvania; J. Ewing Mears, M.D., Gynecologist to Jefferson Medical College Hospital, and Professor of Dental Surgery in the Philadelphia College of Dentistry; W. W. Van Valzak, lately elected Physician to Jefferson Medical College Hospital; John L. Ludlow, M.D., Physician to the Philadelphia Hospital, and Dr. Robert Bollins, a lecturer of much repute on subjects pertaining to materia medica.

Just as we are going to press, intelligence reaches us, from entirely trustworthy sources, that the name of Roberts Bartholow, M.D., of Cincinnati, is prominently mentioned in connection with the Chair.

LAPARO-ENTEROTOMY.—Dr. C. Studsgard has recently performed this operation for the removal of a foreign body from the colon. The patient, a man of thirty-five, had introduced a bottle into his rectum for the purpose of stopping a diarrhoea. The bottle was nearly seven inches long and two inches in diameter at the base. He soon began to feel pain, and was

brought to the hospital. He was then chloroformed. The anus was slit posteriorly as far back as the coccyx and the hand introduced, but it could not be passed through the third sphincter, and the bottle could not be reached. The peritoneal cavity was then opened by an incision along the linea alba. The bottle was found in the sigmoid flexure, from which it was removed and the wound in the gut closed with catgut sutures. The operation was done antiseptically. There was some suppuration afterwards, and recovery was tedious, but eventually occurred.—*Lond. Med. Record.*

GRADED EXAMINATIONS FOR A DEGREE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA.—The Faculty at a recent meeting passed a resolution to the effect that in future the students in the Medical Department entering the final examinations for the degree of M.D., should be graded upon a scale of 100, and that, where the individual grade obtained was high, it should be publicly so announced—the man receiving the highest grade to hold the position of head of the class. This system will first be put into operation during the coming March examinations.

THE FIFTY-THIRD ANNUAL REPORT OF THE MASS. CHAR. EYE AND EAR INFIRMARY, for 1878, is a credit to the surgical staff, Drs. Derby, Shaw, Jeffries, Sprague, Willard, and Blake, on account of the good and successful work accomplished. The report is a model of conciseness and excellent arrangement. "The statistics of cataract operations performed" may be perused with interest and instruction. The officers for the present year are: President, Calvin Ellis, M.D.; Treasurer, F. H. Story; Secretary, E. I. Browne.

UTILIZATION OF BACTERIA.—HYPERDISTENTION OF ABSCESS.—Dr. Byron DeWitt, of Oswego, N. Y., sends us a communication with the above heading. The "gist" of the paper may be summed up as follows: A girl, *æt.* 14 years, suffered from a ranula, which progressively increased in size, in spite of several lancements. Attaining a distending size, it was excised by an eminent New York surgeon. It recurred, and was again removed by excision, and a caustic applied to the open wound. A second time it recurred, and the tumor reached "from the symphysis of the lower jaw to the parotid gland, and half way to the clavicle," when the case was brought to Dr. DeWitt. This gentleman passed a seton in the form of a loop within the tumor, the loop lying upon the floor of the mouth, the ends of the silk being brought out through two separate points of the skin over the swelling. Acute suppuration occurred within the latter and the abscess was opened on the sixth day, discharging a large amount of fetid pus. The seton was left *in situ* for over four weeks, and then removed. The suppurating wound healed promptly. At the end of four years the disease had not recurred.

Dr. DeWitt thinks the acute and putrid suppurative action was set up through the medium of something other than the mere presence of the seton, and believes it was due to the introduction of microscopical germs (bacteria) upon the threads, or by their "worming their way into the sac through the opening made by the needle." Be this as it may, the doctor deserves credit for the success of his treatment of this obstinate case.

SULPHO-THYMATE OF QUINIA.—Signor Cozzolino recommends the *sulpho-thymate of quinia*—a compound of sulphuric and thymic (thymol) acids and quinia—as worthy of ranking beside the sulpho-car-

bolate or salicylate of the same alkaloid. It is freely soluble in acidulated water, in ether, and in alcohol. Dose is the same as the above-mentioned salts. He also calls attention to soda-thymate as a pleasant carminative (dose: 0.50 gmm. for infants; 3.00 to 4.00 gmm. for adults) mouth-wash in aphtha and muquet, as an injection in vaginal, uterine, and vesical affections.

FRACTURE OF OLECRANON.—Mr. Heath, in commenting to the class upon a case of fracture of the olecranon brought into University College Hospital, with a long splint applied and the hand bandaged from the tips of the fingers, said he thought it was time such directions were abolished from surgical works.

TREATMENT OF BALDNESS.—The following is highly commented upon by Dr. George H. Rowe, in the *Atlantic Medical and Surgical Journal*, for seborrhœa and consequent alopecia. It is the plan of Professor Kaposi: R. Saponis viridis (German), alcoholis, $\text{āā. f. } \xi \text{ ij.}$; solve, filtra, et adde ol. lavandulæ, gtt. xx.—xxx. Pour one or two tablespoonfuls upon the scalp, then pour on a little water, rub smartly with the fingers, thus producing a copious lather. After four or five minutes' shampooing this way, rinse the head thoroughly with pure water, then dry thoroughly with a towel. Then apply a little cosmoline. This process causes the hair to fall out in greater abundance at first, but a new and fine growth of hair soon follows.

ICTERIC URINE.—Jaundice may be diagnosed by an examination of the urine with tincture iodine. Pour a little of the tincture upon the urine, do not shake the tube, and three distinct colored layers may be seen—first layer, violet, the tincture itself; below this, a sea-green layer; and the last, the urine in its original color.

TREATMENT OF BLEPHARITIS BY THE APPLICATION OF VULCANIZED INDIA-RUBBER.—The treatment consists in the application every evening to the affected eye of a round plate of caoutchouc, which is covered with a compressive bandage. In the morning the apparatus is removed, and the eye washed with warm water. Dr. Roy reports several cases treated in this way, with very gratifying success. The only phenomenon noticed, on removing the apparatus in the mornings, was a slight redness of the eye.—*Lyons Medical.*

TREATMENT OF WHOOPING-COUGH BY THE TINCTURE OF MYRRH.—According to Dr. Campardon, pertussis yields readily and easily to the tincture of myrrh. He gives fifteen drops in a tablespoonful of Vichy-water every hour or every two hours. This treatment, however, must be combined with the appropriate treatment for the bronchitis or the pulmonary congestion.—*Lyons Medical.*

TREATMENT OF CEREBRAL APOPLEXY BY INJECTIONS OF ERGOTINE.—Mr. Foster reports two cases of pronounced apoplectic coma, which were treated by the injection of twelve drops of a solution of ergotine, containing seven and a half grains to the drachm of vehicle. In both cases the coma disappeared soon, and recovery took place. The essential condition for the success of the treatment is, that the injection be administered at the beginning of the attack, before there has been time for an extensive extravasation of blood. Mr. Foster recommends injecting the fluid between the muscles of the forearm, and not merely under the skin, where it is liable to excite suppuration.—*The Lancet.*

Original Lectures.

A CLINICAL SURGICAL LECTURE.

DELIVERED AT BELLEVUE HOSPITAL,

By LEWIS A. SAYRE, M.D.,

PROFESSOR OF ORTHOPEDIC SURGERY AND CLINICAL SURGERY IN
BELLEVUE HOSPITAL MEDICAL COLLEGE.

SACRO-ILIAC DISEASE, AND ITS DIFFERENTIAL DIAGNOSIS FROM MORBUS COXARIIUS AND SPONDYLITIS.

GENTLEMEN:—We have before us to-day two cases of sacro-iliac disease in the early stage, both of which have been sent to me for disease of the hip-joint; and as this is a mistake so commonly made, and as we also have a child of very nearly the same age of the other two, but who has hip disease in its first stage, I propose to present these cases to you for the purpose of drawing your attention to the minute shades of difference between these two diseases, in order that you may be able to diagnosticate the one from the other without the possibility of an error.

Disease of the sacro-iliac junction is much more frequent than the profession generally suppose, but it is so often mistaken for disease of the hip-joint, or disease of the sacro-lumbar junction, and treated for either one or the other of these diseases for so long a time, that destructive changes occur at the sacro-iliac junction that are sometimes irreparable before the disease has been accurately diagnosticated. It is for this reason that I take the present occasion, with these illustrative cases, to draw your special attention to sacro-iliac disease.

The sacro-iliac articulation is an amphiarthrodial junction between the lateral surfaces of the sacrum and the ilium. The anterior or auricular portion of each articular surface is covered with a thin plate of cartilage, thicker upon the sacrum than it is upon the ilium. The surfaces of these cartilages in the adult are rough and irregular, and separated from one another by a soft, yellow, pulpy substance. At an early period of life, and occasionally in the adult and in the female during pregnancy, they are smooth and lined by a delicate synovial membrane. The ligaments connecting these surfaces are the anterior and posterior sacro-iliac, which generally are so short as to prevent any possibility of motion at this joint; but in certain conditions they become so relaxed as to allow of limited motion, as for instance in the later stages of pregnancy, which allows of an increase in the capacity of the pelvis; but this is a normal elongation. These ligaments may, however, at this time be stretched to such an extent as to be the nidus of future difficulty—the anterior sacro-iliac ligament, which consists of numerous thin ligamentous bands which connect the anterior surfaces of the sacrum and ilium. The posterior sacro-iliac ligament is a strong interosseous band situated in the deep depression between the sacrum and the ilium, behind, and forming the chief bond of connection between these bones. It consists of numerous strong fasciculi, which pass between the bones in various directions. Three of these are of large size; the two superior, horizontal in direction, arise from the first and second transverse tubercles of the posterior surfaces of the sacrum, and are inserted in the rough uneven surfaces at the posterior part of the ilium. The third fasciculus, oblique in direction, is attached by one extremity to the third

or fourth transverse tubercle of the posterior surface of the sacrum, and by the other to the posterior superior spine of the ilium; it is sometimes called the oblique sacro-iliac ligament. These ligaments, as I have before stated, are so short as to allow exceedingly limited motion between the bones.

Disease of this joint is, as I have previously remarked, quite common, and I believe invariably of traumatic origin. Nearly all of the cases that I have seen have been directly traced to a traumatic origin. Two of the cases resulted from the children slipping over from the top of a trunk, down between it and the wall, striking upon the posterior crest of the ilium upon the baseboard which passes around the room near the floor. In another—a severe case—the child, while in a swing, which was being thrown backward and forward with great force, struck over this joint against the wall behind him. These blows, or concussions, produce an extravasation of blood under the interarticular substance, which, not being absorbed, forms the starting-point for an inflammatory action; in fact, an osteitis, or periostitis, which, progressing sooner or later involves the joint, and you have fully developed sacro-iliac disease. Any inflammation at this point produces pressure upon the roots of the sacral nerves, which is made manifest by symptoms at their distal extremities, which resemble in many instances those of spondylitis in the lower lumbar or upper sacral vertebrae. Such symptoms may be: difficulty in urination and defecation, pain in the lower part of the belly, hips, and thighs. But the diagnosis between sacro-lumbar and sacro-iliac disease, or between spondylitis affecting the lower lumbar vertebrae and sacro-iliac disease, is to be made by direct pressure from the sacrum upward, and from the head downward, which, in the case of spondylitis affecting the lower lumbar or sacral vertebrae, will increase the pain, and extension of these parts will give relief. In sacro-iliac disease, however, the pain will not be increased by this procedure, but will be increased by making lateral pressure of the ilii against the sacrum; and by making extension either from the ilium or through the agency of the thigh, relief from pain at the sacro-iliac junction will be given.

The first manifestation of this disease which will probably be observed, will be a peculiar mode of walking, and also of standing. The child will have a peculiar halt in its walk, owing to the fact that pain is produced when the weight of his body is borne upon the limb of the affected side, and he will, therefore, rest the weight of his body upon the leg of that side as short a time as possible, making a quick step with the other leg for the purpose of removing the weight from the diseased one, and upon that leg (the well leg) dwells for a much longer time than the other.

The hip and leg of the affected side are actually longer than upon the unaffected side. In hip disease this elongation of the corresponding parts is apparent and not real, and is dependent upon the obliquity of the pelvis, owing to muscular contraction. In sacro-iliac disease it is actual, owing to the gliding of the ilium downward at the sacro-iliac junction. The actual increase in length can be ascertained by measurement from the umbilicus to the internal malleoli.

I wish now to direct your attention particularly to the different signs between sacro-iliac disease and hip-joint disease, which may be recognized upon inspection. For this purpose we place these two children, standing side by side in a nude state, upon the table, with their backs toward you. We allow them to stand a few moments to get over their excitement and assume their voluntary position; which position will

be that which affords the greatest amount of comfort. You will observe that they both bear the weight upon the right limb, so as to make a solid column to receive the weight of the body. You observe in the little girl (Fig. 1), who has hip disease on the left side, that the gluteo-femoral fold of this side is lower down

FIG. 1.

FIG. 2.

than upon the right side, and that at its external border the crease is entirely obliterated. You observe also that she has her left knee slightly flexed; the thigh of the same side is also slightly flexed, and you will notice that the toes of the left foot are everted, whereas the left foot of the child (Fig. 2) who has sacro-iliac disease upon the left side is projected at the same angle as the right. This eversion of the foot of the child with the diseased hip shows that there is an effusion within the capsule of the joint.

Now inspect the boy (Fig. 2) who has sacro-iliac disease, who, like the girl, bears the entire weight of his body upon his right leg, thus making it a solid column. But you observe that there is no flexion, of either thigh or knee, of the opposite limb, and you see, as I can move it, that he bears no weight upon it, but it is swinging almost clear of the table. This unequal distribution of the weight of the body upon the lower extremities is produced by the patient bending his trunk to the right, thus elevating the pelvis upon the diseased side and allowing the limb, by its own weight, to remove pressure from the inflamed surfaces.

Observe now the trunks of these two children: the boy with the sacro-iliac disease has his body bent to the right, so that a plumb line dropped from his occipital protuberance passes midway between the fold between the buttocks and the trochanter major of the right side; whereas the child with the hip disease stands with her body slightly bent forward, owing to the contraction of the psoas magnus and the iliacus internus muscles. The feet of the child with the sacro-iliac disease are symmetrically projected in front, but the child with the diseased hip has the foot of the affected side abnormally everted.

We now lay these two children upon their backs upon this firm table, as a mattress or soft bed would so accommodate itself to the inequalities of the body as not to serve our present purpose. We will first direct our attention to the child with the diseased hip. As she lies upon her back we lift both of her lower extremities upward until the entire length of the spine touches the table, so that you cannot pass the hand beneath it. We now move the limbs from side to side until we have the pelvis at a right angle with the trunk, so that a line drawn from the centre of the sternum, over the umbilicus to the centre of the symphysis pubis, will be at a right angle to a line drawn from one anterior superior spinous process of the ilium to the other. When these lines are at right angles to each other, and the spinous processes touch the table, the pelvis and trunk are at right angles with one another, and if there be no disease either within the hip-joint or the muscles that control its movements the limbs can be so extended that the popliteal spaces can be made to touch the table without disturbing the approximation of the spine to the table or the rectangular position of the lines drawn from the anterior part of the body before referred to. We now put this principle to the test, and you observe that the girl's right limb falls upon the table, and by pressing over the knee I bring the popliteal space down so as to touch the table, and have made no elevation of the spinous processes at all so long as I hold her left limb in its upright posture. We now drop the left limb upon the table, and you observe how it remains bent at the knee, while the spinous processes still touch the table as before; but as I press the knee down so that its posterior surface touches the table, you see how instantly the curvature takes place in the lower portion of the spine, so that my assistant glides his hand directly underneath: this is owing to the contraction of the psoas magnus and iliacus internus muscles, which is one of the signs of the early stages of hip disease.

We will now try the same experiment with the child who has sacro-iliac disease. Raising his limbs, we have now the spinous processes upon the table, and the lines before mentioned are at right angles with each other. You observe that as I drop the right leg it comes completely down and no curvature of the spine is produced. I drop the other leg, and it also falls to the table. I now press the popliteal spaces of both legs down upon the table without the slightest elevation at any point of the spinous processes from the table.

We now turn again to the child with the diseased hip-joint. You see her left leg is flexed and slightly abducted. By taking hold of it and pressing the head of the femur into the acetabulum, you see that she instantly winces on account of the pain produced. By making slight extension, she says it feels better. When I make extension and attempt to move the limb, you observe that I can flex the thigh only to a right angle before the pelvis begins to move; whereas I flex the limb upon the right side until the knee touches the trunk, and yet the pelvis is not moved. I can abduct, adduct, and rotate the right limb, as you see, with perfect freedom, there being no rigidity of the muscles upon this side. The moment I attempt these same movements upon the left side, you see the entire body moves as if the hip were ankylosed; in fact, the limb and trunk move together like a solid statue. Now while my assistant holds the pelvis still, I take hold of the thigh above the knee, on the diseased side, and make gradual extension for a short time, and you observe that while this extension is continued I can

make quite free motion at the diseased joint, but the moment this extension is removed and the muscles allowed to contract, the diseased surfaces are brought in contact, and now you see no motion is possible, and the limb becomes, as before, rigid and apparently ankylosed at the hip.

We take the little child with sacro-iliac disease, and you observe that I can flex either limb until the knee touches the thorax. I make abduction, adduction, and rotation on one side as well as upon the other, both hip-joints being perfectly normal. By making direct pressure upward, I produce no pain whatever upon the right side, but by making pressure in the same manner upon the left side he winces slightly, which is one of the symptoms of disease within the hip-joint; but, as you observe, this symptom is not connected with any rigidity of that joint, and pain is therefore produced because pressure has been carried through that joint up to the sacro-iliac junction. When I make pressure directly upon the trochanter major of each side, I give rise to only slight, if any, pain, but when I crowd the ilia together you see how instantly he winces under the agony produced. We therefore exclude in his case *all* disease of the coxo-femoral articulation, and locate it in the sacro-iliac junction of the left side.

You will thus see that by a careful observation of the exact position which different portions of the body will assume under the influence of reflex muscular contraction, and the voluntary attitudes which patients will assume for the purpose of relieving diseased surfaces from pressure, and by extension and compression, you are enabled to locate the disease with an accuracy that cannot be mistaken.

By placing my hand over the diseased sacro-iliac junction I observe an increase of temperature over that of the same locality upon the opposite side. In this case it is so marked that it is readily detected by the naked hand, but in many instances it is not so conspicuous. Under these circumstances the variation in temperature between the two can be made evident by the delicate surface thermometer of Dr. Seguin, which I have found of great use in the diagnosis of obscure cases of this sort.

Having now arrived at a positive diagnosis, we are ready to consider the subject of treatment. In the first place, as there is an increased heat or elevated temperature over the seat of inflammation, we shall apply a half dozen leeches and increase the bleeding by warm fomentations, after which we shall apply ice-bags to the part, protecting the skin by one or more thicknesses of flannel between the ice-bag and the skin as may be necessary to give comfort to the patient. During the mean time the patient is placed in bed, and extension and counter-extension upon the sacro-iliac junction is made. This is done by means of strips of adhesive plaster, placed upon either side of the thigh and leg, and secured by a properly adjusted roller bandage. At the end of the strips of adhesive plaster short tabs of webbing are sewed, which extend beyond the heel. A cross-bar connects the ends of these tabs, and from the middle of this cross-bar a cord extends over a pulley at the foot of the bed, and is attached to a weight for the purpose of continuous extension; the foot of the bed is raised eight or ten inches by placing bricks or blocks under the legs so that the body may become a counter-extending force. As the acute symptoms subside, blisters may be occasionally required; and if the disease still continues, it may be necessary sometimes, and often is, to apply the caustery over the sacro-iliac junction. You should apply your iron at a white heat, and carry it firmly and

rapidly over the line of the junction. The application of the hot iron will often be found to relieve pain when nothing else will; the actual cautery will produce an impression upon the deep-seated tissues, causing them to contract, and aid in restoring the circulation of the part to its normal condition.

The disease is ordinarily of long continuance, and confinement in the horizontal posture may be injurious to the general health; and it therefore becomes necessary, if possible, to carry out the same principles of treatment, and, at the same time, give the patient the benefit of out-door exercise and fresh air. This can be very readily accomplished by increasing to a considerable extent the thickness of the sole and heel of the shoe to be worn upon the foot of the unaffected side. In order to lift the patient so that the diseased limb will swing clear of the ground, the weight of the limb of the affected side may be all that is required to give ease to the inflamed joint; but if not, it can be readily increased by adding some lead to the sole of the shoe of this side, when, by the aid of crutches, or the aid of a wheeled crutch, the patient may be permitted to take exercise in the open air with benefit to the general health and without injury to the affected joint. When the horizontal position is again resumed, of course the extension is to be applied as before.

Prognosis.—From my own experience in the treatment of a number of cases, some eighteen in number, I should say that the prognosis was good; in fact, in the majority of cases detected in the early stage and properly treated, the result would be a good recovery. In making this statement I am somewhat surprised to find that I differ from almost all other surgical authorities. Dr. Erichsen says, in his *Science and Art of Surgery*: "The prognosis of this disease is always most unfavorable." "I have never seen a case recover after the full development of the disease and after suppuration had set in." Holmes, in his *System of Surgery*, says: "The prognosis in these cases is always unfavorable, but becomes especially so when matter has once begun to form." Ashurst says: "The prognosis of sacro-iliac disease is always unfavorable." Professor Gross, one of our greatest American surgical authorities, says: "The prognosis is always unfavorable; now and then, it is true, a case recovers, but such an occurrence is very uncommon."

Gentlemen, I have now had under my personal attention and observation eighteen cases of this disease, seventeen of whom have entirely recovered. Six of them, when treatment was commenced, had gone to the point of suppuration, requiring a free opening of the abscesses and the removal of more or less necrosed bone. The only death which has occurred among the eighteen cases which I have seen will be found fully recorded in my work upon *Diseases of the Joints*, page 332; but in this case it will be observed that, after I had made a diagnosis of sacro-iliac disease, the case left me, and was treated for two years for diseased hip-joint. At the end of this time he returned to the hospital for treatment, but died in a few days thereafter; and upon post-mortem examination both hip-joints were found perfectly healthy, but there was a carious condition of both sacro-iliac junctions. May it not be possible that the unfavorable prognosis heretofore so generally given, may be due to the fact that the cases did not come under treatment in their early stage, and that the disease, by being early detected and properly treated, would frequently result in recovery? If such be the case, the time which we have occupied in the consideration of these two cases will not have been in vain.

CLINICAL LECTURE ON SEBORRHOEA.

DELIVERED AT THE PENNSYLVANIA FREE DISPENSARY
FOR SKIN DISEASES,

By JOHN V. SHOEMAKER, A.M., M.D.

SEBORRHOEA OLEOSA.

GENTLEMEN:—The first patient whom I shall bring before you is a young woman, twenty-two years of age, a seamstress by occupation, who has been troubled with a greasy appearance of the forehead and cheeks. The nose, in addition, presents a red, shining, and oily look, with here and there enlarged cutaneous vessels. This is one of the varieties of seborrhœa, and consists in an increase of the sebaceous secretion. It may occur upon any part of the body, and more especially the forehead and nose. The diseased patches, in this case, are attended with a burning sensation. The ducts of the sebaceous glands are so much enlarged that they are apparent to the eye. This unctuous skin has a soiled appearance from the dust and dirt that has adhered to its surface. By rubbing over the parts a piece of blotting-paper the increased secretion is absorbed, and the paper looks as if it had been dipped in oil. This greasy and shining condition of the skin is a source of much annoyance to this young woman, on account of the disfigurement it gives to the countenance. In some individuals the secretion is poured out in such quantity as to collect in clear or yellowish drops over the surface.

Nature has supplied abundantly the entire surface of the body—except the palmar and plantar surfaces—with sebaceous glands, which secrete this peculiar substance. These glands exist in large numbers on the scalp, face, back, chest, scrotum, and labia; and they are the parts that are usually attacked by seborrhœa. This material, called sebum, which the glands secrete, removes abnormal products from the blood, acts as a protection and a defence to the skin, serves to retain moisture in the tissues, lubricates the hair, and gives softness and pliability to the integument. It assists in retaining moisture in the eyes and prevents the lids from adhering. It also prevents the entrance of dust and insects into the external auditory meatus of the ear, and keeps the external membrana tympani and the external canal moist. In certain animals, as the skunk, the fox, and the muskrat, this unctuous substance of the skin emits a powerful odor, which acts as a defence and a protection, and it is likewise a means of making known to each other their hiding-places.

This sebaceous material consists of a fluid principle, olein, and two solid constituents, stearin and margarin. When the secretion increases in quantity, and the fluid part—the olein—predominates, we have a diseased condition, named *seborrhœa oleosa*—the variety of the affection that troubles this patient. On the other hand, should the solid portions of sebum be in superabundance, the affection is then known as seborrhœa sicca, and will appear as scales on the skin.

Seborrhœa oleosa can be caused by any irritation or derangement of any part of the system. It is more common in the female than in the male sex. It occurs especially in those who are out of health, in persons who are anæmic, debilitated, and poorly nourished. It is most common at the age of puberty, when there is much activity of the sebaceous glands. In this case the health of the patient is very much impaired, she is anæmic, and shows strong evidence of having general debility, all of which could easily have caused this affection. Cold winds, negligence

of washing, local irritants, nervous debility, and a disordered condition of the internal organs, frequently induce glandular congestion, and so *seborrhœa*.

The treatment in seborrhœa oleosa consists in the use of both general and local remedies. It is necessary, in the first place, for the patient to have plenty of fresh air, daily exercise, and the most nourishing form of food. The iron preparations are required on account of the anæmic condition of the patient. The tincture of the chloride of iron will be the most suitable form, in fifteen-drop doses, three times daily, in a wineglassful of water; should constipation follow, a change can be made to the syrup of the lactate of iron. The liberal use of bitter tonics, the mineral acids, and the preparations of pepsin, are often demanded in this affection.

The local treatment is of the utmost importance. The disease is usually stubborn, and only yields after patient and careful attention to the parts. The patches can be washed frequently with a mild soap, and dusted over with either starch, bismuth, lycopodium, or precipitated carbonate of zinc. The use of the cold bath will be of great service by causing the enlarged glands to contract. The application of a mild stimulating lotion of acetate of lead and sulphate of zinc will also prove very beneficial in many cases.

I would, however, more particularly recommend for this patient a mild, stimulating soap that I call *sapo matricaria et sulphuris*. It is composed of one and a half ounces each of oil of theobroma and olive oil, two drachms of powdered German chamomile flowers, one drachm of precipitated sulphur, and one ounce of a weak solution of caustic soda. This soap has been prepared at my suggestion by Mr. L. Wolff, chemist and pharmacist, of this city (Philadelphia). I have several very fine specimens of this soap, which I will pass around for your inspection. You will see it has a very pleasant and agreeable scent. All these spots should be well washed with it every other evening just before retiring.

SEBORRHOEA SICCA.

I next present this patient, Jas. R.—, bookkeeper, nineteen years of age, having a large collection of scales over the scalp and a portion of the back and chest. The crown and sides of the head are covered with dry scales and thick crusts, with adherent hairs. Over some portions of the head the crusts are firmly adherent to the scalp, while upon other parts the scales are loosely situated, and in falling off cover the patient's clothes with a scurfy material. Upon removing some of the thickened crusts from the crown of the head, masses of sebum are found to be prolonged down in many of the follicles, some of the ducts are obliterated, and the scalp is also red and swollen. It likewise presents some spots having a dull and withered appearance. The hair is dry, lustreless, very thin, and the patient complains of a constant itching sensation of the scalp. These masses of sebum that plug up the follicles interferes with the growth of the hair, leads to all this unhealthy state of the scalp and the hair, and often ends in premature baldness.

The secretion of these glands that are so abundantly developed on the scalp are very great during the intra-uterine period. The first year of the child's life this excessive secretion frequently continues, and when neglected, and allowed to collect dust and dirt, it irritates the skin, and often produces eczema. In old age, and in syphilis, the scalp is sometimes covered with these dirty, yellowish masses of sebum, which causes the loss of hair in the latter affection.

Upon the patient's back, between the scapule, and

over the chest, mainly on the sternum, are dirty yellow crusts in large numbers in both localities. Some of these patches are small, about the size of a silver five-cent piece, and others are large from several of them coalescing. The skin of both the back and chest is slightly greasy, a small number of scales are observed scattered about the patches, and the ducts of the follicles are open and filled with sebum. These sebaceous crusts exist in some cases on the forehead, nose, and cheeks, and both Biett and Bazin relate a case in which the sebaceous glands over the whole surface were filled with inspissated sebum. The genital regions of both sexes are frequently attacked with seborrhœa, on account of the parts being so abundantly supplied with sebaceous glands. In the male, the glandule tysonii seu odorifere of the corona glandis and of the cervix of the penis secrete a peculiar soft, white and caseous material, which frequently becomes copious, rapidly decomposes, especially when the prepuce is long, gives off an unpleasant odor, and occasionally causes balanitis. In the female these sebaceous glands are situated around the labia and clitoris, and frequently pour out the secretion in large quantity, giving rise to a diseased condition of the parts.

This patient has a tuberculous family history, and it is evident on his countenance. His hair and complexion are both light, and his extremities are cold, showing the feeble state of the circulation. In addition, he has been troubled for some years with constipation, and by this reflected irritation could very easily give rise to this affection. Tuberculous subjects are especially disposed to both seborrhœa and acne. The causes I mentioned in connection with the first case may likewise bring about this same form of seborrhœa, providing the solid principles of the sebum, the stearin, and margaric should predominate.

Seborrhœa might be mistaken for eczema or lupus erythematosus. It differs from lupus in the following points: Should a crust or scale be removed in seborrhœa, it will be found to be prolonged down in the follicle, the skin beneath being pale or slightly reddened; while in lupus the part is both reddened, swollen, and infiltrated. Again, seborrhœa is a functional disorder, and is never followed by scars; while lupus is a new cell growth, and there is always a tendency to repair by the formation of cicatrices.

The treatment for the patient will be both local and constitutional. He should take daily exercise and plenty of good, nourishing food. I shall also prescribe a bitter tonic three times daily, and the extract of malt, one tablespoonful in a glassful of milk, with meals. As soon as the patient's digestive organs are in the proper condition, we will change these remedies for one tablespoonful of cod-liver oil with ten drops of the syrup of the iodide of iron, three times daily, one hour after meals. The following mild aperient pill will be very beneficial for the sluggish condition of the bowels: powdered aloes and rhubarb, each, twenty grains; extract of hyoscyamus, six grains; extract of belladonna, one grain; and oil of cinnamon, one drop. Make twelve pills. Dose, two every other night, when necessary. The crusts and scales must be removed by oil dressings. The patches on both the head and body should be soaked with olive oil until the masses become soft and can be easily removed. If, however, the crusts on the head should still adhere, then a flannel cap, saturated with oil and covered with oil-silk, should be tied on at bedtime and allowed to remain about ten or twelve hours. After the crusts and scales have been thoroughly macerated, the dressing should be removed, and the parts well washed

with tepid water and the *sapo matricaria et sulphuris*. About every second or third evening, a copious lather should be made from the soap, and actively rubbed into the scalp and the patches over the body. The parts should then be sponged with tepid water and rubbed dry with a rough towel. I have used this medicated soap in dispensary and private practice, in seborrhœa and the various scaly eruptions, with remarkably good results. In seborrhœa it will cause the enlarged glands to contract, the skin to become healthy, and the disease to disappear.

After using the soap, the following preparation will be a very good and elegant application to lubricate and soften the dry condition of the hair and the scalp: beef marrow, two ounces; white wax, half an ounce; tannate of quinia, one drachm; balsam of Peru, three drachms; oil of rose, five drops; oil of verbena, three drops; essence of ambergris, one-half a drachm. Mix, and use daily as a pomade.

Original Communications.

ACUTE INFANTILE INTUSSUSCEPTION, WITH THE HISTORY OF THREE CASES.

By W. W. HEWLETT, M.D.,

BABYLON, L. I.

The slipping of a portion of intestine within another portion of intestine, constitutes an intussusception, or an invagination. It consists of two distinct portions, an external or receiving portion, forming the sheath, and an internal or protruding portion, forming the plug. The sheath consists of one, and the plug consists of two cylinders. There is a receiving, an entering, and a returning layer; and consequently two mucous and two peritoneal surfaces oppose each other. Owing to the traction of the mesentery the plug never lies parallel with the sheath, but always in the form of a curve, or a coil. Owing to the length of the plug, and to the degree of traction of the mesentery, is the obstruction of the intestinal tube, partial or complete. The lengthening takes place mainly at the expense of the external portion—the external peritoneal layer of the intussusception becomes *inverted* much more readily than its internal mucous layer becomes *everted*. Intussusception may occur at any part of the large or small intestines; the most frequent point being the lowest part of the ileum, a portion of the ileum becoming prolapsed through the ileo-cæcal valve.

Out of forty-five fatal cases referred to by J. Lewis Smith, thirty-eight began at this point. It is less frequent entirely in the small than in the large intestines. It is so rarely found entirely in the small intestines that even M. Rilliet asserts that intussusception never occurs there, but this has been disproved by more than one observer. This variety of intussusception rarely or never occurs before the age of three months. In the fifty-two cases recorded by Smith, twenty three occurred between the third and the sixth month. Leichtenstein says, "the first year after the third month is remarkable for a special frequency." In a collection of twenty-five cases by Rilliet and Barthez there was none under the age of four months. It is remarkable that no case has been reported under the age of three months.

* Abstract of a paper read before the Suffolk County Medical Society.

The *morbid anatomy* varies according to the duration of the disease. Primary inflammatory invaginations are always descending.* As soon as the invagination occurs the central becomes in effect a foreign body, excites peristaltic action, and is forced farther and farther down the alimentary canal. The compression and dragging to which the implicated mesentery is subjected, causes venous obstruction, with swelling and sanguineous infiltration of the central portion, producing bloody exudations from its mucous surface. If life be prolonged, peritonitis is developed, which is generally limited to the invaginated part, and produces adhesions between the opposing serous surfaces. In recent cases the lesions are merely those that are produced by compression, viz., swelling and sanguineous infiltration of the mucous coats. In protracted cases there is more or less gangrene of the central portion. The gangrene is more to be observed at its neck and at its extremity, the effects of traction and compression being more exerted at the ends of the central portion. The central portion is in some cases entirely separated by mortification, and is discharged in a single piece, or it may be discharged gradually in small shreds. In either event union and cicatrization of the intestinal tube may ensue, and be followed by the recovery of the patient. In exceptional cases, where general peritonitis occurs, perforation of the intestine from over-distention takes place above the point of intussusception. The length of the central portion varies from a few inches to a foot or more. The sheath of the intussusception becomes greatly reduced in length, which accounts for the fact that the invaginated part may be felt in the rectum, when only a very short portion of the large intestine enters into the formation of the central portion.

In treating of the *causes* of intussusception we must first consider the fact that in the large majority of cases the displacement begins with a protrusion of a portion of the ileum through the ileo-caecal valve. Anatomical peculiarity, therefore, takes precedence among the predisposing causes. Sex is also mentioned as a predisposing cause. It is true that the disease occurs more frequently among males than in females; but it is not also true that male infants, as a rule, are more susceptible to the various influences that produce disease, and have less vitality than female infants? A favorable condition for intussusception may be presented by a tetanic or tonic contraction of the circular muscular fibres of the intestine, and a distention of the intestinal canal below the point of contraction, from the accumulation of flatus, thus producing tenesmus and increased peristaltic action. Paralysis of a limited portion of the intestine may operate as a cause of intussusception; also the receipt of injuries, or an intestinal polypus. Iliac tenesmus, or caecal tenesmus from irritation of the ingesta, may produce a prolapse of a portion of the mucous membrane of the ileum through the ileo-caecal valve, in the same way that rectal tenesmus plays such an important part in the production of prolapse of the rectum.

The *symptoms* of intussusception are usually developed suddenly. The infant begins to cry violently without apparent cause. The nurse finds herself utterly unable to soothe it. A natural evacuation from the bowels may occur. Vomiting is the first prominent symptom that awakens fear. The vomiting soon becomes persistent and frequent. In a few hours one or more small bloody passages occur. If, after a hasty examination, the physician prescribe merely for the symptoms, he will increase the child's

suffering, and add to the terrible dangers of the disease. If he make a careful examination of the abdomen he may find an elongated tumor, which is generally located in the right or the left iliac region. He may feel a tumor in the rectum, or possibly protruding from the anus. The blood that is passed will be slightly mixed with mucus or serum; the bowels are obstinately constipated. If a cathartic have been administered he will be informed that the baby threw it up. The further progress of the cure will be greatly influenced by the treatment. Should a cathartic be given that is retained until absorption occurs, all of the symptoms will be intensified, and to those above described will be added that of tenesmus. The temperature is normal at first, but after two or three days, if life be prolonged, peritonitis will be developed, and we then have the symptoms of that disease superadded. The pain is paroxysmal in character; vomiting is rarely or never absent. It may become stercoraceous, but this is believed to be exceptional. In infants, above the age of twelve months, hemorrhage from the anus may not be observed.

It is a very important diagnostic symptom. Meteorism, to a greater or less extent, is always present. Convulsions in some cases, though rarely, take place. West says: "In the majority of cases convulsions come on a few hours before death, which always takes place within a week." In the three cases of which the histories are herewith presented, convulsions did not occur in either, and one case survived until the tenth day. Meigs and Pepper say: "Death takes place within five days, as a rule." In thirty-three cases embraced in the statistics of J. Lewis Smith, the largest number of deaths took place on the third day. This agrees with the statement of Vogel, who says: "As a rule, death takes place on the third or fourth day." The disease may *terminate* in apparently spontaneous reduction and recovery, which is extremely rare; but two cases illustrative of this happy termination are cited by West. It may terminate in recovery by reduction from artificial means; also by sloughing of the invaginated portion, which, so far as has been ascertained, has never yet occurred under the age of thirteen months. According to Lichtenstein, "the separation takes, in the majority of cases, from the eleventh to the thirteenth day;" but this observation has reference to cases of all ages. Cases are referred to where the symptoms of invagination became chronic, and continued for weeks and even months, but these cases doubtless occur only in children above the period of infancy. Death may occur from collapse, peritonitis, or from exhaustion.

There is no absolute pathognomonic symptom of the disease, and it is difficult, particularly in the early period of the attack, to make the *diagnosis*. Intussusception may be confounded with acute indigestion; gastritis from poisoning; acute dysentery; colic; cholera infantum; and with other forms of internal strangulation of the intestine. The sudden development of abdominal pain in an infant above the age of three months, with persistent vomiting, soon followed by bloody stools and tenesmus, point very strongly to intussusception. If the presence of an abdominal tumor of recent occurrence can be ascertained, there can scarcely exist a doubt as to the special character of the disease. If, with the above described symptoms, a tumor can be felt in the rectum, a positive diagnosis can at once be made.

What are the indications for *treatment*? *First*, the relief of pain; *second*, the reduction of the displaced intestine; *third*, the prevention of inflammation.

The first indication is to be accomplished by the use

* Vide Ziemssen's Cyclopaedia, Vol. VII., p. 611.

of opium, which not only relieves pain, but arrests peristaltic action and tenesmus, thus preventing a still further descent of the invaginated bowel. Reduction should be attempted as early as possible, either by injections of warm water, or of air or gas, or by the introduction of an œsophageal sound, with a sponge attached, in the rectum; and lastly, by opening the abdominal walls. Inflammation is to be prevented by keeping the intestines as quiet as possible with the free use of opium, by applying soothing remedies externally, allaying nausea and vomiting, and by giving only that kind of nourishment that leaves the least residuum. Where meteorismus is excessive, the intestine may be punctured with a fine trocar, and the pent-up gas allowed to escape. If the lesion be wholly within the small intestines, our efforts at reduction by injections will be unavailing, for it has been repeatedly shown that the ileo-cæcal valve will rupture before it will allow of the passage of fluid into the ileum. Should the invaginated portion be within reach of the finger, an attempt may first be made to push it up with the œsophageal sound and sponge. This method, that is known as Nisson's, has alone been sufficient in a few cases in effecting reduction. At least it will prove serviceable by giving more space in which to operate with injections. In using the injections, a fountain, or a Davidson's syringe should be employed. The water should be lukewarm. After introducing the nozzle of the syringe, the fingers of the left hand are to be used in compressing the soft parts about the anus, which will tend to prevent a regurgitation of the liquid. When a considerable amount of liquid is injected, the abdomen should be gently manipulated with the hands. It will generally be found that only a small quantity of liquid will remain, the larger proportion being rapidly and forcibly ejected. If no appreciable amount of liquid be retained, another attempt should be made, by gentle manipulation with the sponge and sound, to push the tumor above the rectum; afterward the injection is to be repeated. If this prove unsuccessful, the infant may be allowed to rest for an hour or two, when the injection is to be repeated. After sufficient trials in this way, if relief be not obtained, a resort should be had to inflation. For this purpose a common pair of bellows may be used, to the nozzle of which an elastic tube may be attached. The latter is to be introduced, if possible, high up in the rectum. J. Lewis Smith recommends for this purpose two or three quart bottles of highly charged carbonic acid water, with the portion of a tube of a Davidson syringe. Either of these means, in a very small minority of cases, may prove successful; but whether water, air, or gas be forced into the rectum, it is essential to produce a marked degree of distention; also that the patient should be as nearly as convenient in the inverted position, and while distended, the abdomen should be gently manipulated by the hands. In the event of failure of these means, after repeated and satisfactory trials have been made, what are we to do? Are we to give up all active attempts, and devote our efforts to the prolongation of life, hoping that the invaginated gut may slough, and be followed by the recovery of the patient? This would be a perfectly admissible plan of treatment, and one that would doubtless be followed by the great majority of practitioners. So far as has been ascertained, the youngest child that has recovered after mortification and discharge of the gut took place, is thirteen months.* The chances for recovery, then, for an infant under one year of age,

and under these circumstances, are so slight that this purely *expectant* plan of treatment is almost equivalent to abandoning it to a fatal termination. The preponderance of authority in the department of diseases of children is averse to the operative method of reduction. Dr. H. B. Sands operated successfully in the case of an infant aged six months.*

What do the surgeons say? Erichsen (page 818 of *The Science and Art of Surgery*, second London edition): "If, however, it can be satisfactorily made out that there is an internal obstruction, and more especially if the intumescence can be felt, it will evidently be the duty of the surgeon to give the patient his only chance." Bryant (page 297 of *The Practice of Surgery*): "Operation in intussusception is scarcely justifiable." Holmes (page 619, vol. iv., in the edition of 1870): "The proposal to open the abdomen should not be sustained." The writer herein also explains his disbelief in the injection of air or water. Gross (page 677, vol. ii., fifth edition of *The System of Surgery*): "In internal strangulation depending on a twist, an invagination, or the interception of the bowel through an aperture in the omentum, the diagnosis is so uncertain that the proper time for relief is usually allowed to pass before the operation is decided upon, and when at last it is performed, the case must almost necessarily result fatally."

Hamilton (page 769, second edition of *A Treatise on Surgery*): "It is only in adults that such a procedure could encourage any hope of success."

The paper closes with the following assertion: Where the diagnosis of intussusception is *positive*, after proper and judicious attempts, without relief, have been made in an infant that has been previously healthy, that subsists on natural food, whose parents are free from constitutional vice, where the operation can be performed before local peritonitis has occurred, within the first twenty-four or thirty-six hours, it can scarcely be doubted that the operation of laparotomy is justifiable.

THREE CASES OF ACUTE INTUSSUSCEPTION IN INFANTS.

CASE I.—Male, age five months. Had occasional attacks of colic and indigestion. The general condition of the child had always been good. Was summoned at night, Sept. 5th, 1872. Found the patient apparently suffering severe pain. Vomiting occurred after every time of nursing. Bowels had not moved for nearly twenty-four hours. A dose of castor-oil that had been given was promptly rejected. Ordered Dover's powder and calomel in combination (two to three grs.), and warm fomentations to the abdomen; also, should powder be vomited, to give an enema. Three hours after was summoned in haste, and found all of the symptoms intensified. Two bloody evacuations from the bowels had occurred: An examination of the abdomen revealed nothing abnormal. With the index finger in the rectum I could distinctly feel an elongated tumor, w. l. h. was at once recognized as an intussusception. The subsequent treatment consisted of frequent and copious injections of warm water, opium as indicated, and brandy. The child was allowed to nurse to a moderate extent. Vomiting occurred frequently, but did not become stercoraceous. On the fourth day the abdomen became tympanitic and tender; the patient was feverish; slight muco-sanguineous discharge occurred two or three times daily until the tenth day, when death took place suddenly.

On post-mortem examination the abdominal cavity

* Vide J. Lewis Smith's *Diseases of Children*, fifth edition, page 675.

* Vide *New York Medical Journal*, for July, 1874.

was found to contain a large quantity of gas and liquid feculent matter that poured through an opening in the ileum. Perforation had taken place from extreme distention, as the small intestine at this point was equal in size to the large intestine. The central portion of the intussusception, including a portion of the cæcum and about ten inches of the ileum, was tightly forced downward into the large intestine, the latter being greatly puckered up and forming the sheath of the intussusception. The entire mucous surface of the central portion was very much swollen, and at a point near its neck there was marked discoloration from gangrenous inflammation. There were slight adhesions between the opposing peritoneal surfaces, and numerous patches of exudative plastic material were perceived at and also in places remote from the local lesion. Hemorrhagic discoloration in numerous places on the peritoneal surface of the small intestines, and dilatation of the blood-vessels of the mesentery, were observed.

CASE II.—Male, aged four months, had been in excellent health up to the last day preceding my visit (Aug. 16, 1873). The child began to cry violently, and after a few hours vomiting took place. A mustard plaster was applied to the epigastrium, and three grains of hydrarg. cum creta were directed to be given. Eight hours after having prescribed the above I first saw the patient. The child had cried almost incessantly, and vomited everything it took. The bowels had moved once after taking the cathartic, and the evacuation was perfectly normal in appearance. The abdomen was tender on pressure over a small space a little to the right of the umbilicus, but was everywhere else uniformly soft and natural. An enema of tepid water was given, which was promptly rejected. The finger introduced into the rectum came in contact with a protruding mass, and after its removal was found to be soiled with a bloody discharge. Opium was then given in sufficient doses to render the patient comfortable. Repeated efforts were made with a pair of bellows by inflation, and with the syringe by injections of tepid water, to reduce the invagination, but all failed. There was little or no fever at any time, and the general treatment was that as described in connection with the history of the preceding case.

Death took place on the fifth day. No post-mortem examination was made.

CASE III.—Female, aged five months. Had always been healthy. Was one of the good babies that "never cried." First saw the patient about 10 A.M., Oct. 16, 1874. The child slept well the night previous until 4 A.M., when it commenced to cry, and the mother says "kept it up for three hours, when it fell asleep." After about three-quarters of an hour it awakened, and cried until my arrival. The bowels had moved naturally the day before, a bloody evacuation had occurred that morning. The child had vomited three or four times since 4 A.M. On examination of the abdomen an elongated tumor was found in the left lumbar region, which was somewhat tender on pressure. No tumor could be felt with finger in the rectum. Ordered warm fomentations to the abdomen and a warm-water injection. Left a solution of sulphate of morphia to be given as required to relieve pain. Saw patient again at 6 P.M. Two bloody stools had been passed, and the child vomited after every period of nursing. Had slept a good deal during the day, which was due to the morphia. The mother had given two injections, but they came right away. On exploring the rectum with the finger a tumor was felt high up, which was pronounced an intussusception. The treatment of this was similar to

that adopted in Case II., but in addition, in order to effect a reduction, an attempt was made with a piece of rubber tubing, to which a sponge was attached. The sponge having been introduced into the rectum, it was pushed up gradually and slowly, while the abdomen was gently manipulated externally. While treating this case I was surprised on the morning of the fourth day by the intelligence which was brought by the father, that the child was so much better that I need not go to see it. "The bowels moved and the baby has had a comfortable night." Curiosity impelled me to visit the child, who was found very comfortable from the action of the opium, and by abstaining from efforts to reduce the invagination for several hours. The evacuation consisted of mucus slightly tinged with blood. The abdominal tumor and the rectal tumor were *in statu quo*. Death occurred on the seventh day. A post-mortem examination revealed the existence of an intussusception, which consisted of the cæcum and nearly eight inches of the ileum. The mucous surfaces were very red and much swollen. The peritoneal surfaces were lustreless and discolored from hyperæmia in the immediate location of the intussusception, but everywhere else they presented a perfectly natural appearance.

Progress of Medical Science.

ACUTE SAPONINE-POISONING AND THE VALUE OF SAPONINE AS A LOCAL ANÆSTHETIC.—In 1867 Eugene Pelikan expressed the belief, as the result of physiological experiment, that saponine would in time come to play a role of some importance as a local anæsthetic. Köhler also experimented with the drug on frogs, rabbits, and dogs; but, while thinking it possible that it might have a future as a local anæsthetic, he laid great stress on the dangers connected with its entrance into the circulation (paralysis of the heart, of the vaso-motor and respiratory centres). Schroff gave it internally to men in doses of as much as two grains without producing poisonous effects, and thought that its action in depressing the pulse and temperature might make it useful in hypersthenic fever. Eulenburg seems to have been the first to employ the substance clinically. He injected it hypodermically in three cases of neuralgia; but, while all the painful, local and alarming general symptoms of the drug were produced, the neuralgia was not relieved. Finally Dr. Keppler, in order to determine the real value of saponine as a local anæsthetic, undertook a series of experiments on himself, and the following are the results obtained and the conclusions he drew from them.

In each experiment he injected 0.1 gramme (gr. iss.) of saponine into the inner side of the left thigh. The immediate local effect was the development of a cutaneous inflammation resembling erysipelas, but much more painful. This inflammation increased in violence for twenty-four hours, remained stationary for the same length of time, and then diminished rapidly. The general symptoms produced by this violent local irritation were the same as would be excited by any very painful injection. The specific local effects of the saponine—anaesthesia of the point of injection to other irritants—set in about fifteen minutes after the injection, and persisted less than fifteen minutes. The area of the anaesthesia was identical with that of the paleness caused by the injected solution, *i. e.*, it extended as far as the saponine solution spread in the subcutaneous tissue, and bathed directly the ends of

the nerves. Of the specific general effects of the drug the most important was undoubtedly its action on the temperature. This rose steadily for three hours, and then fell gradually to the normal point, which it reached within twenty-four hours. For the next two days there was some fever, but on the fifth day the temperature was far below the normal point, reaching the collapse point of 93°. The pulse also was somewhat elevated during the first three days, and fell on the fifth day to sixty-five per minute. The rise in the temperature during the first three days was evidently due to the violent local inflammation, and it would have been much more excessive had it not been for the specific depressing action of the drug on the pulse and temperature; this manifested itself in its full power on the fifth day, after the local inflammation had subsided. The fact that the drug could exert such a powerful action five days after a single injection is evidence of its slight diffusibility; this same quality would make its excretion from the body more difficult, and hence it must be classed among the drugs with cumulative action.

Other general effects of the drug were marked bodily and mental depression, somnolence, and salivation. The pain, exophthalmus, and strabismus of the left eye, and the greater depression of the temperature on the left side (2½° on the fifth day) must be ascribed to direct alteration of the nerve-centres, while the pain in the knee and hip, and the swelling of the glands in the left groin, were evidently due to direct transmission of inflammation.

The conclusion Dr. Keppler draws from his experiments is, that saponine does not deserve to be mentioned among the anesthetics that can be utilized in surgical practice. As an antipyretic, however, it is more deserving of consideration, the dangers connected with its administration not being sufficient to counterindicate its careful employment. Its subcutaneous administration is unfortunately very painful, but not more so than hypodermic injections of corrosive sublimate. In fact, the violent local irritation produced by the injections superadds a derivative to the antipyretic action of the drug, which, in his opinion, would make it especially valuable in the treatment of those cases of acute pleurisy and pneumonia that are attended by high fever and threatening cerebral symptoms, and also of those malignant cases of endo- and pericarditis that run a course resembling that of a severe typhus. The maximum dose to be employed should not exceed one grain. Moreover, it is well known that an intercurrent erysipelas sometimes leads to the rapid absorption of inflammatory indurations, and even of specific tumors; and as the anatomical changes in the skin produced by saponine injections closely resemble those of erysipelas, Dr. Keppler suggests a methodical trial of the injections in cases of sarcoma, lupus, etc., inaccessible to operation, in the hope of thereby bringing about resorption.—*Berliner klin. Wochen.*, Nos. 32, 33, and 34, 1878.

A CASE OF ASTHMA MILLARI.—Dr. Jacobs, of Cologne, reports the following case of this disease, which is so rare, that in an extensive practice of forty-five years, he has only met with eight or ten cases of it. The patient, a girl seven years of age, had been suddenly seized while in bed with a violent attack of suffocation. She was perfectly conscious, her voice was not in the least hoarse, the face and extremities were covered with a cold sweat, the lips were blue, the pulse was small and could scarcely be counted, and, in a word, all the symptoms of collapse, with cyano-

sis, were present. The respiration was exceedingly difficult, all the accessory inspiratory muscles being called into play. The child gasped for air, but expelled the air again immediately. Auscultation revealed only weak respiratory murmur and scarcely appreciable heart-sounds. There were no abnormal sounds in the larynx or bronchi, and no fever; the abdomen presented nothing abnormal; the bowels and bladder had recently been evacuated; there were no throbbing of the carotids and no swelling of the jugulars. The tongue was clean and moist, and the child put it out readily. The diagnosis was asthma millari, and the prognosis was unfavorable, because death very frequently occurs in the first, and almost invariably in the second attack. If, however, the attack be not repeated within twenty-four hours, the patient generally recovers. The treatment consisted in irritation of the skin and pharynx, drawing out and pressing down the tongue, and the administration of musk. One-third of a grain of musk was given every half-hour, and four hours later the doctor found the child sitting up in bed, playing, and to all appearances perfectly well. A careful examination then revealed nothing abnormal, and particularly no redness or swelling of the laryngeal mucous membrane. The after-treatment consisted only in nourishing diet, and rest in bed for two days, with pleasant occupation. The attack has not been repeated, and the prognosis is now favorable, as the disease has never been observed after the eighth year, and the patient will soon attain that age.

The post-mortem appearances in the fatal cases of asthma millari that have thus far been recorded have been negative, with the exception of hyperemia of the lungs and the presence of small blood-congula in the right heart. In two of his own cases Dr. Jacobs found, in addition to the pulmonary congestion, petechial suffusions on the pleura pulmonalis, in the heart, and in the aorta. He believes the affection to be entirely distinct from the so-called asthma thyriceum or laryngismus stridulus, and from spasmus glottidis infantum. The diagnostic points from those affections are: 1. Asthma millari attacks only children from two to eight years of age, and especially girls. 2. It attacks children of well-to-do parents rather than those of the poor. 3. The attack sets in suddenly without previous illness, without catarrhal manifestations, and without demonstrable cause. 4. The voice remains clear and the speech distinct. 5. The sensorium is unclouded. 6. There are no abnormal sounds, such as a cry or stridor. 7. The health of the children in the intervals between the attacks is perfect. 8. The affection is not attended by fever. Numerous remedies have been recommended for the affection in addition to musk, ex. gum camphor, asassaftida, potassium bromide, belladonna, clysters of chloral hydrate, subcutaneous injections of morphine, inhalations of amyl nitrite and chloroform, touching the pharynx with liquor ammonii caustici, etc., but Dr. Jacobs has had no practical experience with any of them.—*Deutsche med. Wochen.*, September 21, 1878.

ARSENIC IN GREEN LEATHER.—Two officers in Königsberg recently suffered from eruptions on the head, which came on after they had been wearing for a short time helmets lined with green leather. One of them, a colonel, was for a time even dangerously ill. A chemical examination showed that the leather with which the helmets were lined contained arsenic.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, February 15, 1879.

THE ADULTERATIONS OF FOOD AND MEDICINE.

At the last meeting of the Medical Society of the State of New York, Dr. E. R. Squibb, of Brooklyn, presented the draft of a proposed law for the detection and punishment of adulterations of food and medicine. As it is quite likely that the bill will soon be brought to the attention of the State Legislature, we take the opportunity of presenting a synopsis of its provisions.

It is not saying too much to assert in advance that the document has been prepared with great care, and that every suggestion tending towards its efficiency has been heeded; in fact, the draft is the result of thorough discussion of the subject by a Joint Committee of the New York Academy of Medicine, the New York Academy of Sciences, the Medical Society of the County of New York, the Therapeutical Society, the New York College of Pharmacy, the Medico-Legal Society, and the Public Health Association. Taking advantage of the experiences of the English "Sale of Food and Drugs Act," certain defects are guarded against in the present bill; for instance, general definitions as to what constitutes adulterations are carefully avoided, and specific ones presented instead. Again, the question as to intent to defraud is not considered, it being sufficient to establish the fact of fraud to secure conviction.

The question as to what constitutes adulteration in food or medicine is one, the consideration of which naturally presents itself in this connection. "Food" is defined as embracing every article used for food and drink, or in the food and drink of man and animals; while the term "medicine" is held to include every other article used for the preservation of health or the relief and cure of disease in man and animals, embracing antiseptics, disinfectants, and cosmetics.

A standard of purity is made by dividing articles of food into two classes, simple and compound. The

standard of simples is fixed at the average quality of the substances in their natural condition (when so used), or after preparation by drying, grinding, packing, etc., without damage, according to the best methods, and without the admixture of foreign substances beyond what is essential—as salt in meat—to their preservation in a wholesome state. The standard for compound articles is fixed by the publicly known formulas according to which they should be compounded, or the labels or descriptions fixed to the compounds as sold or offered.

The standard for simple articles of medicine is that made by the United States Pharmacopœia. When any medicine is not embraced in the list of the Pharmacopœia, the statement of some commonly accepted standard of authority is to decide respecting the purity of the article. If the simples are pure, the compound must be pure; and hence the formula, recipe, or label is here held to be conclusive as to the compound it calls for. In patent medicines, the testimony of the owner's private formulas is conclusive, provided always that no compound shall contain any poisonous or hurtful ingredient not specified on the label; a baking powder containing alum, or a cosmetic containing lead—neither being stated upon the label of the compound—subjecting the seller to all the penalties of wilful adulteration. A patent medicine containing any such deleterious or toxic ingredient not plainly shown on the label, subjects the proprietor to prosecution and penalty.

The adulteration of articles of food or medicine consists, first, in adding one or more substances to another, as corn-meal in flour, whereby the strength, purity, quality, or value of the substance is reduced, with the effect of tending to deceive the public; secondly, as in artificial wines or mustard, in the substitution of one substance for another; thirdly, as in skim milk or partly exhausted tea, coffee, or drugs, in the abstraction of any part of the substance with the effect to reduce its value; fourthly, as oleomargarine for butter, in the application of a name belonging to one substance to another substance, thus tending to deceive the consumer; and, fifthly, in the presence in any substance of any impurity or foreign matter, either natural or accidental, if in unusual proportion, as dirt in food or medicine, and metallic salts in canned goods.

Whenever different qualities of the same are mixed together, adulteration is charged. The same is said for dilution of any kind, as water in milk, the addition of coloring, coating, or polishing matter, etc., are also defined as adulterations.

There is no doubt that the parts of the proposed bill defining adulterations and laying the foundations for such legal action as may be necessary, are as complete and perfect as human foresight can make them. The question regarding the carrying out of the law is one which will, however, invite discussion, and will

doubtless give rise to differences of opinion upon the subject. Dr. Squibb proposes that the duty of prosecution shall be imposed upon a State Bureau of Health, which shall have special boards of inspection and prosecution, and which boards shall be competent to act on the complaint of any consumer of an adulterated article.

We do not presume at present to offer any suggestions as to the working of such a law, reserving any comments thereon until the plan is perfected, and until such time as it shall be ready to be presented to the Legislature.

RESTRAINT IN THE TREATMENT OF THE INSANE.

IN the care and treatment of the insane, the question of mechanical restraint has for many years received the greatest attention from alienists. The reaction from the old horrors of the chain, the dungeon and the lash, led at first to a great deal of sentimental nonsense, which culminated finally in the denial by many leading authorities of the value or need of any mechanical restraint at all.

Such views could not long be sustained, however, and they never had very wide prevalence in this country. At the present time, while the utility of restraint is generally acknowledged, very great efforts are being made every year to get along with the least possible amount. For it are substituted watchful care, regular work, drilling exercises, or whatever occupation may tend to teach the patient self-control. According to Dr. Shew, Superintendent of the Connecticut Hospital for the Insane, ninety per cent. of patients are now treated in American asylums without any mechanical restraint. This percentage has been increased especially within the last ten years.

It is pleasant to be able to record the declining years of that hideous array of apparatus which used to act with such happy reciprocity in narrowing the liberty and comfort of the patient, while enlarging that of the attendant.

STRENGTH OF THE VARIOUS SCHOOLS OF MEDICINE.

THE Illinois State Board of Health has recently collected statistics which show very accurately the distribution of the medical men of that State. As every practitioner is obliged to obtain a certificate from this board, there is an opportunity of obtaining his status which has been carefully improved. The total number of physicians is 4,950; of these, 3,646 are Regular; 437 Homœopathic; 456 Eclectic; 37 Physio-medical; not stated, 336; all others, 38.

It will thus be seen that while the proportion of the Estray to the Regulars is sufficiently large to remind us that the ladies continue to like Homœopathy and kindred delusions, it is not as large as has been claimed by some. It is to be remembered also that Illinois is one of the few States which supports, upon the afflu-

ence of a five thousand dollar income, both an Eclectic and a Homœopathic medical school.

REPORT OF THE SURGEON-GENERAL OF THE NAVY.

WHEN the previous annual report for 1877 appeared, we referred to the fact that the examining board had not been able to find good enough men to fill the vacancies in the service. In the recent report for 1878, it is stated that there are only six of these vacant places at present remaining.

The severe competitive examinations have resulted in securing to the navy a superior class of medical men; and the report testifies to the efficiency of their services. There are recorded 10,457 cases of disease, injury, etc., which were treated. The mortality was two per cent.

SUBSTITUTES FOR ALCOHOL.

WE find that the efforts of temperance reformers are turned much more than formerly towards introducing some substitute for alcohol. Failing in the direct attack they are attempting a flank movement. There is now manufactured to meet in part these demands a series of aerated waters which equal many wines in delicacy of flavor. Ales and beers with an inappreciable amount of alcohol, and wines from unfermented grapes are also made, and form agreeable drinks, which may, to some extent, satisfy the demands of social occasions. For the weariness that follows muscular or mental exertion, the best things are food and rest. If drinks are craved, however, we have in thin oatmeal or Liebig's extract of meat, foods which enter the circulation so rapidly that their effect is comparable to that of alcohol. These, it is suggested, may be aerated and made enduring by various additions. Tea, and especially coffee, are also available and useful in these cases. For the reforming drunkard, bitter infusions may be of service in addition to the drinks already mentioned.

It seems possible that some advance may be made by temperance reformers through efforts in this direction, and since, as a rule, man is better without alcohol, they should have the help of the medical profession.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

THE recent meeting of the State Medical Society was the most successful and interesting one that has been held for many years. A large number of very valuable papers were read, and much important business was transacted. The address of the President was a model of its sort, and its wide dissemination, as recommended by the Society, will greatly aid the cause of State Medicine. It is, however, unnecessary to review the meeting in detail, and we only refer to it here, in a general way, to call the attention of our readers to the full report elsewhere.

Reports of Societies.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Seventy-Third Annual Meeting,

HELD IN ALBANY, FEBRUARY 4TH, 5TH, AND 6TH, 1879.

TUESDAY, FEBRUARY 4TH.—FIRST DAY.—MORNING SESSION.

THE Society met, pursuant to adjournment, in the city of Albany, at 10 o'clock A.M., and was called to order by the President, DR. D. B. ST. JOHN ROOSA, of New York.

Prayer was offered by Rev. HORACE C. STRONG.

INAUGURAL ADDRESS.

The President, in his opening address, directed attention to a few facts illustrative of the condition of the medical profession in the State of New York.

The number of colleges in affiliation with the Society were eight. Of those, *six* were exclusively attended by male students; *one* by women, and *one* by men and women. The whole number of students attending medical lectures in the State for the session of 1878-79, was 1,965. The number of graduates from the various colleges in the State, in the year 1878, was 526. There were nine medical journals published in the State. Thirteen new volumes on medical subjects, by American authors, had been published during the year, besides several new editions and many reprints of foreign books. The various county societies maintained their organizations, but, aside from cities and large towns, scientific work done in them was meagre. Besides the various county societies, there were thirty-eight other organizations for the purpose of discussing medical subjects. Reference was made to the publications of the Kings County Medical Society, and to the Medical Register of New York, New Jersey, and Connecticut, under the supervision of the New York Historical Society. The value of such a register could hardly be over-estimated. If the work could be carried on by this Society as it had been done by the private organization that had it in charge, it would become what it could not be considered now—an official guide to our profession.

The President suggested whether the Society might not take some action in that direction.

The functions of the Society were chiefly performed by its scientific work. Its legislative duties, fortunately, were few. Its alliance with the State was chiefly honorary.

The address was closed by appropriate reference to strengthening each other by the recital and discussion of professional experience, and the Society at once proceeded to the transaction of further business.

ANNOUNCEMENT OF COMMITTEES.

The President then announced the following committees:

For Business Committee—Drs. J. C. Hutchison, J. W. S. Gouley, and J. V. Kendall.

For Committee of Arrangements—Drs. Wm. H. Bailey, F. C. Curtis, and the Secretary, Dr. Wm. Manlius Smith.

For Committee on Credentials—Drs. J. H. Hinton, W. S. Ely, and S. G. Wolcott.

For Committee on Ethics—Drs. W. C. Wey, E. M. Moore, and A. L. Saunders.

For Member of Nominating Committee appointed by the President—Dr. E. R. Squibb.

COMMUNICATIONS FROM COUNTY SOCIETIES.

DR. DIMON, of Cayuga Co., presented a communication with reference to collecting the names of those members of the profession who had lost their lives in the pursuit of science or exposure to epidemics, and that such list be published in the transactions of the State Medical Society. Referred to Business Committee.

Communications were presented from Oneida Co. and Greene Co., which were referred to Committee on Publication.

DR. CASTLE, of New York, presented a communication from the Medical Society of the County of New York, with reference to certain instructions which the delegates from that county had received concerning amendments to the by-laws.

On motion made by Dr. Wyckoff, of Buffalo, the communication was referred to the Committee on By-Laws, with instructions to report upon the same at the next annual meeting.

RESOLUTIONS.

DR. G. W. COOKE, of Otego, offered the customary resolution extending an invitation to the Governor and the members of the Legislature who were physicians, to be present and participate in the transactions of the Society. Carried.

DR. L. E. FELTON, of St. Lawrence, offered a resolution asking that the Legislature be petitioned to repeal all acts empowering boards of censors of the various county societies to issue certificates to practice medicine.

Referred to Committee on By-Laws, with instructions to report at the next annual meeting.

DR. CASTLE, of New York, offered the following resolution:

Resolved, That the Committee of Publication be requested to consider and report to the Society, at this meeting, the feasibility of a scheme for the publication of the transactions which would avoid the assessment of county societies for the expense of publishing the scientific papers included in the transactions. Carried.

REPORT OF THE COMMITTEE ON CODIFICATION OF THE BY-LAWS.

DR. ALEX. HUTCHINS, of Brooklyn, submitted a complete report, which, on motion by Dr. Piffard, was referred to the Committee on By-Laws, to be reported upon next year. On motion, the committee was discharged.

Inquiry into the legality of the resolution passed by the Medical Society of the State of New York, in 1872, requiring county medical societies to institute a preliminary examination of the qualifications of young men purposing to commence the study of medicine. Instituted by the Society.

DR. HUTCHINS presented a report, according to the above instruction, which was referred to a special committee, consisting of Drs. Wey, Squibb, Hutchins, Vander Poel, and Kendall.

ESTIMATION OF UREA.

DR. SQUIBB read a brief paper upon the above subject, the chief object of which was to correct an error which appeared in the paper of Dr. Maurice Perkins, published in the transactions for last year.

The decimal by which to multiply should be .00269 instead of .0269. [See Trans. for 1878, pp. 45-46].

REVISION OF THE UNITED STATES PHARMACOPOEIA IN 1880.

DR. SQUIBB read a communication upon that subject, and offered a resolution providing for the election of a committee of *three* to represent the Society in the convention which would meet in 1880. Believing it to be for the best interests of the Pharmacopœia, he made the special request that he should not be elected to serve upon the committee.

The resolution was adopted.

The paper and the communication were referred to the Committee on Publication.

CONTRACTED KIDNEY.

DR. W. S. ELY, of Rochester, read a paper upon the above subject, and reported two cases.

The *first* belonged to a class frequently seen, and the *second* was regarded as somewhat exceptional with reference to symptoms. In the first, seventy-one ounces of urine were passed in twenty-four hours, and had a specific gravity of 1012, a trace of albumen and a few casts.

In the second case the patient passed an average of 104 ounces of urine for twenty-three days, without the slightest evidence of albumen or casts, but with a low specific gravity. There was no visual disturbance, nor headache nor nausea nor vomiting. Special reference was made to the insidious nature of the affection, to the fact that albumen and casts might be absent from the urine for many days in succession, to the importance of measuring the urine passed during the entire twenty-four hours, and noting its specific gravity.

Dr. Ely also suggested that it was a question whether there was any such thing as diabetes insipidus without renal changes and without renal contraction. The paper was discussed by Dr. Vander Poel, of Albany, and referred to the Committee on Publication.

PRESIDENT'S ADDRESS.

DRS. A. HUTCHINS, F. A. CASTLE, and F. R. STURGIS, were appointed Committee on the President's Address.

FRACTURE OF THE FEMUR.

DR. NORMAN L. SNOW, of Albany, then read a paper in which was recorded the treatment of twenty-five cases of fracture of the femur occurring in private practice.

All were treated by extension and counter-extension. Plaster-of-Paris was sometimes employed *late* in the treatment of the case. Compound fractures justified the early use of the plaster-of-Paris bandage.

The paper was referred to the Committee on Publication.

MEDICAL EDUCATION.

DR. A. MERCER, of Syracuse, read a paper in which he discussed the relations of the medical student and the medical profession to the question of medical education.

It was discussed by Drs. Sturgis, Vander Poel, Castle, and Sherman, and then referred to the Committee on Publication.

The Chairman of the Committee of Arrangements introduced DR. CLARKSON F. COLLINS, a representative of the Massachusetts State Medical Society.

MEMBERS BY INVITATION.

DR. W. H. BAILEY also announced the following as members by invitation: Wallace Clark, of Utica; D. H. Clark, Lorenzo Hale, H. J. Fellows, E. B. Tefft, J. P. Boyd, Jr., and Geo. F. Stevens, of Albany; B. A. Mynderse, of Schenectady; C. W. Hamlin, of

Middleville, Herkimer Co.; P. R. Farbeck, of Gloverville; A. P. Ten Eyck, of De Forestville, Rensselaer Co.; and Wesley Newcomb, of Cornell University, Ithaca.

TUMOR OF THE CEREBELLUM.

DR. GEORGE T. STEVENS, of Albany, reported a case of tumor of the cerebellum, with remarks. The growth occupied about one-half of the fossa, and weighed one and a half ounces. It was composed of fibrous connective tissue containing groups of nucleated cells.

It was regarded as a neuroma of the auditory nerve.

DR. ROCKWELL, of Brooklyn, read a paper on

INTRA-CRANIAL TUMORS.

It consisted chiefly in the report of a case interesting in two particulars: 1. The extreme rapidity of development, twenty-seven days only elapsing after the appearance of first symptoms until development of phenomena, which made the case unmistakable; 2. The determination of the situation of the tumor by means of the surface-thermometer.

The paper was discussed by Dr. Thos. R. Pooley, of New York, and referred to Committee on Publication.

The Society then adjourned to meet at 3 P.M.

FIRST DAY.—AFTERNOON SESSION.

The Society was called to order by the President at 3 P.M.

REPORT OF THE COMMITTEE ON BY-LAWS.

DR. WEY, Chairman of the Committee on By-Laws, reported that the Committee had approved of the By-Laws of the Medical Society of the County of Chemung, and also of the County of Otsego.

Unofficial reports had been received from the County of Saratoga, and also from the County of New York, but the Committee felt unwilling to approve of them.

The report was laid upon the table until the report should be received from the special committee asked for by Dr. Hutchins.

COMPENSATION OF MEDICAL EXPERTS.

DR. DIMON, of Cayuga, read the bill passed by the Senate at the last session of the Legislature, and referring to compensation of medical experts. The bill failed to pass the Assembly.

The Committee proposed to continue its efforts, and should endeavor to have the bill introduced in the lower house during the present session of the Legislature.

SECTIONS OF THE BRAIN.

DR. J. C. DALTON, of New York, exhibited specimens and described a method of showing sections of the brain in its fresh condition, with retention of color and normal relation of parts.

The brain was first imbedded in a strong solution of gelatine, enclosed in a brass frame-work. By means of a long, thin knife, sections were then made, and as soon as made transferred to another frame, imbedded in gelatine, and covered with a glass plate.

LUPUS.

DR. H. G. PIFFARD, of New York, read a paper upon the treatment of lupus.

It will be published in a future number of the RECORD.

SYMPATHETIC GLAUCOMA.

DR. D. WEBSTER, of New York, read a paper upon the above subject, and reported two cases. Under ordinary circumstances we should have expected sympathetic iritis. It seemed to him, however, that in both cases the glaucoma was direct consequence of the injury received.

A NEW AGENT IN THE TREATMENT OF GLAUCOMA.

DR. THOS. R. POOLEY, in a brief paper, gave the results of his experience in the use of *sulphate of eserine*, especially in the treatment of acute glaucoma. He had used it in four cases. Its great value consisted in the power it had to produce temporary improvement, by which the patient could be prepared for an operation.

DR. H. D. NOYES, of New York, remarked in way of caution, with reference to expecting too much from the use of the remedy. In one case he had employed it without producing any benefit whatever; yet he regarded it as a valuable remedy for controlling this severe and important disease.

With reference to sympathetic glaucoma, we had not sufficient data to enable us to arrive at definite conclusions.

DR. KNAPP, of New York, referred to a case of glaucoma, in which a cure was effected by the use of *eserin*. The strength of the solution he used was one grain to three or four drachms of water, and employed three or four times a day.

The papers were referred to the Committee on Publication.

PAPERS READ BY TITLE AND REFERRED TO THE COMMITTEE ON PUBLICATION.

On "Ovariectomy," by Dr. C. G. Pomeroy, of Wayne Co.

On the "Incubation of Scarlet Fever," by Dr. C. G. Bacon, of Fulton.

THE RELATION OF THE MEDICAL PROFESSION TO THE ABUSE OF MEDICAL CHARITY.

DR. F. R. STURGIS, of New York, read a paper upon the above subject, which was referred to a special committee, consisting of Drs. Jacobi, Castle, and Noyes, of New York, to be reported upon on Wednesday.

BIOGRAPHICAL SKETCHES.

Biographical sketches of Dr. Albert Gallatin Purdy, by Dr. H. W. Carpenter, of Oneida, and Dr. Jehiel Stearns, of Pompey, by Dr. Kneeland, of Onondaga, were referred to the Committee on Publication.

DR. H. P. FARNHAM offered the following resolution:

Resolved, That the Committee on By-Laws be requested to report concerning the revision of the by-laws of the Medical Society of the County of New York at this meeting, as otherwise said society would be without by-laws for this year. Carried.

MEMBERS BY INVITATION.

DR. BAILEY reported the following as members by invitation: L. C. B. Graveline, Willis G. Tucker, John Thompson, Amos Fowler, Eugene Van Slyck, and John B. Stonehouse, of Albany; Clarkson C. Schnyler, of Troy; Herman Knapp, of New York City; and D. M. Wilcox, of Lee, Mass.

COMMITTEE ON NOMINATIONS.

For *First Senatorial District*—Dr. J. H. Hinton, of New York; For *Second Senatorial District*—Dr. Wm.

Govan, of Rockland Co.; For *Third Senatorial District*—Dr. C. A. Robertson, of Albany; For *Fourth Senatorial District*—Dr. Thompson Burton, of Montgomery Co.; For *Fifth Senatorial District*—Dr. H. N. Porter, of Oneida Co.; For *Sixth Senatorial District*—Dr. Joshua B. Graves, of Steuben Co.; For *Seventh Senatorial District*—Dr. Jonathan Kneeland, of Onondaga Co.; For *Eighth Senatorial District*—Dr. C. C. Wyeoff, of Erie Co. Dr. E. R. Squibb, of Kings Co., appointed by the President.

PERMANENT REMOVAL OF HAIR BY ELECTROLYSIS.

DR. G. H. FOX, of New York, read a paper upon the above subject, and gave a description of the instruments used and the manner of performing the operation.

DR. PIFFARD exhibited a compound microscope attached to a spectacle-frame, which could be used with advantage in the operation.

The paper will appear in a future number of the RECORD.

BAPTISIA TINCTORIA IN THE TREATMENT OF TYPHOID FEVER.

DR. LAURENCE JOHNSON, of New York, read a paper upon the above subject, and reported *seven* cases. It was believed to have a beneficial action upon the disease when administered in doses of the tincture varying in size from one to three drops every hour or two hours.

DR. SQUIBB thought that physiological experiments should precede pathological experimentation before the value of any remedy in the treatment of disease could be satisfactorily determined.

DR. JOHNSON remarked that the physiological action of the drug had been thoroughly studied by the homeopaths, but that he did not feel at liberty to introduce the results thus reported.

DR. JACOBI was unwilling to accept the drug as one possessing any special efficacy in the treatment of typhoid fever until all measures commonly resorted to for reducing temperature were excluded, such as until the fact that the tendency of the disease was to moderate within the third week, was taken into consideration, and until we know something more of its physiological action.

The paper was further discussed by Drs. Kneeland and Piffard, and then referred to the Committee on Publication.

LAPAROTOMY IN INTESTINAL OBSTRUCTION.

DR. J. P. CREVLING, of Cayuga, presented the statistical merits of this operation in two classes of cases: 1. Obstruction from intussusception; and, 2. Obstruction from all other causes. For information he had drawn largely upon a report made by Dr. H. B. Sands, of New York, and also from the writings of Dr. Ashurst, of Philadelphia, published in 1874.

His conclusions were as follows:

1. That abdominal section for the removal of intestinal obstruction was not only justifiable, but eminently proper, in cases of intussusception as soon as milder means had failed.

2. That the operation should be immediately performed, provided the conditions were at all formidable; but if symptoms of strangulation, peritonitis, hemorrhage, etc., had occurred, the operation was not warrantable.

3. When the obstruction occurred from intussusception, the operation should be performed at once.

4. That there was no real danger in the operation itself had been claimed by many.

CARBONIC ACID GAS AS AN ANTISEPTIC.

Dr. E. M. MOORE, of Rochester, discussed Dr. Crevling's paper, and referred to the use of carbonic acid gas to prevent the entrance of air into the abdominal cavity, in any operation in which the cavity was opened.

The paper was then referred to the Committee on Publication.

PAPERS READ BY TITLE AND REFERRED.

On "Ovarian Tumors," by Dr. John Davidson, of Queens Co.

On "Thrombosis and Embolism," by Frederick Hyde, of Cortland Co.

DISLOCATION OF THE ACROMIAL EXTREMITY OF THE CLAVICLE DOWNWARD.

Dr. WALTER B. CHASE, of Windham, reported a case of the above character. The patient was a boy *right* years of age, who received a blow directly upon the top of the shoulder.

Dr. MOORE, of Rochester, suggested that it was possibly a case of epiphysal fracture, which was more likely to occur at that age than dislocation.

The paper was then referred to the Committee on Publication.

Dr. JOSHUA B. GRAVES, of Corning, reported a case of

INSTRUMENTAL DELIVERY.

The paper was referred to the Committee on Publication, and the Society adjourned to meet at 8 P.M.

FIRST DAY—EVENING SESSION.

The Society was called to order at 8 P.M. by the President.

SCIENTIFIC GHOSTS.

Dr. JOHN C. DALTON read a paper upon the above subject, in which he gave an interesting account of certain old theories, such as "the theory of organic molecules" [Buffon], and "the theory of inclusion" [Bonny]. It was a pleasing semi-scientific entertainment in the interval of more scientific communications.

ADDRESS ON OPHTHALMOLOGY.

Dr. H. D. NOYES, of New York, gave a broad and graphic outline of the progress which had been made in ophthalmology during the past century, and illustrated his subject by means of the lantern and screen.

The Society then adjourned to meet on Wednesday morning, at 9.30 o'clock.

WEDNESDAY, FEBRUARY 5TH—SECOND DAY—MORNING SESSION.

The Society was called to order at 9.30 A.M., by the President.

Prayer was offered by Rev. J. HURPSTONE.

The minutes of the sessions of the previous day were read and approved.

MEMBERS BY INVITATION.

Dr. BAILEY, Chairman of Committee of Arrangements, reported the following as members by invitation:

Drs. S. B. Ward, C. S. Merrill, and W. J. Lewis, of Albany; Clinton Wagner, W. A. Hammond, and G. M. Beard, of New York; W. F. Bennett and D. R. Burrell, of Canandaigua; E. T. Rulison, Bath-on-the-Hudson; C. Sawyer, Au Sable Forks, Essex Co.; B. Wilson, Wolcott, Wayne Co.; Wm. Bassett Fish, Lake-

ville, Conn.; L. H. Hills, Cooperstown; George U. Smith, Rondout; T. M. McLean, Elizabeth, N. J.; and A. S. Coe, Oswego.

TREASURER'S REPORT.

Dr. CHARLES H. PORTER, of Albany, Treasurer, presented his report, which was referred to an auditing committee.

ABUSE OF MEDICAL CHARITY.

Dr. JACOB, Chairman of the Committee on the paper read by Dr. Sturgis yesterday, moved that the paper be referred to the county medical societies. The question was too important to be discussed in a short space of time. Carried.

Dr. CASTLE, of New York, moved that the paper be printed and distributed to all the county medical societies as soon as practicable. Carried.

COLLATION AT THE DELAVAN HOUSE.

Dr. BAILEY, in behalf of the Albany County Medical Society, extended an invitation to the State Medical Society to attend a collation at the Delavan House this evening, after the delivery of the President's Address.

RHINOPLASTY.

Dr. A. C. POST, of New York, reported a case and exhibited photographs illustrating an operation of rhinoplasty for the correction of a deformity produced by the kick of a horse.

Referred to the Committee on Publication.

COMMITTEE TO COLLECT NAMES OF PHYSICIANS WHO HAVE LOST THEIR LIVES IN THE PURSUIT OF SCIENCE OR IN EPIDEMICS.

The President announced the following committee: Drs. Dimon, of Cayuga Co., H. D. Didama and Wm. Manlius Smith, of Onondaga Co.

PROPOSED LAW TO PREVENT THE ADULTERATION OF FOOD AND MEDICINES.

Dr. E. R. SQUIBB made a report upon the above subject, which was referred to the Committee on Publication. The proposed law was printed in the New York daily papers.

PAPERS READ BY TITLE AND REFERRED TO COMMITTEE ON PUBLICATION.

"Personal Observations upon One Hundred Cases of Cancer," by Dr. Thomas E. Satterthwaite, of New York; "Report of a Case of Catalepsy," by Dr. B. S. Hovey, of Rochester; "Obituary Notice of Samuel Hart, M.D.," permanent member of the Society from Kings Co., by Dr. R. M. Wycoff, of Brooklyn.

Dr. W. C. WEY, of Elmira, then reported

TWENTY-EIGHT CASES OF EFFUSION INTO THE PLEURAL CAVITY REQUIRING ASPIRATION.

Dr. W. S. ELY, of Rochester, referred to the history of one of the cases reported by Dr. Wey, and described the method he employed for retaining the drainage-tube in position, which was employed to keep the pleural cavity free from accumulations of pus.

The rubber tube used for securing drainage was passed through an opening, in a rubber plate, slightly smaller than the size of the tube. Over this a thin rubber band was placed which went around the body and held the tube in position. It was connected to a bottle, which contained a solution of carbolic acid, by means of small rubber tube, and the bottle could stand upon the floor or be carried in the patient's pocket.

Dr. JACOB, of New York, discussed the paper and referred to the propriety of removing sections of ribs,

especially in adults, for the purpose, in empyema, of favoring sinking in of the walls of the chest and consequent closure of the cavity.

PAPERS READ BY TITLE AND REFERRED.

"Gangrene of the Leg produced by Embolism," by Dr. John Vedder, of Schenectady.

"Report on School Hygiene for the Town of Saugerties," by Dr. John Vedder. Referred to Committee on Hygiene.

"On Diabetes Mellitus," by Dr. N. C. Husted, of Tarrytown.

"Report of the Committee on Hygiene," by Dr. E. V. Stoddard, of Rochester.

ANATOMICAL RELATIONS OF ACUTE INFLAMMATION OF THE MIDDLE EAR.

DR. J. S. PROT, of Brooklyn, read a brief paper upon the above subject, in which was set forth the importance of early paracentesis of the drum membrane for the relief of acute inflammation of the middle ear.

The paper was discussed by Drs. F. H. Hamilton, D. Webster, and H. D. Noyes, of New York.

INVITATION TO VISIT THE NEW CAPITOL.

An invitation was extended to the Society, by Mr. Palmer, to visit the New Capitol at 7.45 P.M., and listen to an explanation by Lieut.-Gov. Dorsheimer of two allegorical paintings in the Assembly Chamber.

Invitation accepted with thanks.

ON THE USE OF JAVORANDI OR PILOCARPIN IN THE TREATMENT OF PUERPERAL CONVULSIONS.

DR. FORDYCE BARKER, of New York, read a paper upon the above subject, which will be published in a future number of the RECORD.

The paper was referred to Committee on Publication.

NON-ASYLUM TREATMENT OF THE INSANE.

DR. W. A. HAMMOND, of New York, read a paper upon the above subject, in which the position taken was that the medical profession in general was as well qualified to treat the insane as they could be treated in insane asylums. In many cases sequestration was not necessary, and in many others it was positively injurious.

The commencement of the trouble was usually recognized by the ordinary medical practitioner, showing his qualification at the most important stage of the disease. Asylums were not curative. For those who had comforts of home, and were not dangerous either to themselves or to others, asylums were not only not necessary, but were highly pernicious in their influence upon the patient.

The paper was discussed by Dr. G. M. BEARD, of New York, who stated that he had found in practice that many patients in the early stage of insanity could be treated successfully at home, provided they had sensible friends. He was often called upon to decide whether or not to send cases to asylums or treat them at home, and had never repented of having decided to use home treatment. The subject had occupied his thoughts for some years. He cited several cases illustrating his position, but disclaimed all hostility to asylums. We needed asylums, and more of them. In regard to asylum or non-asylum treatment, each case of early insanity must be judged by itself, taking into account the nature and scope of the malady and whole environment of the patient.

The paper was referred to the Committee on Publication.

The Society then adjourned to meet at 3 P.M.

SECOND DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P.M., by Dr. S. O. Vander Poel, of Albany.

ON THE TREATMENT OF HEMORRHAGE IN ABORTION.

DR. W. T. LUSK, of New York, read a paper upon the above subject, which will appear in a future number of the RECORD.

The paper was discussed by Dr. Fordyce Barker, of New York, and Dr. R. H. Sabin, of West Troy.

DR. BAILEY introduced to the Society Dr. O. G. SELDON, delegate from the Wisconsin State Medical Society; also DR. ARNER M. SMITH, of Pittsfield, delegate from the Massachusetts State Medical Society.

MEMBERS BY INVITATION.

Drs. S. A. Russell, P. J. Keegan, T. K. Perry, Harriet A. Woodward, O. D. Ball, of Albany; A. W. Shirland and R. H. Sabin, of West Troy; Wm. H. Hays, of West Albany; Wm. H. Robb and Jas. H. Seoon, of Amsterdam; E. E. Brown, of Lowville, Lewis Co., and G. D. Dunham, of Plattsburgh.

DR. JOHN P. GRAY, of Utica, read a paper on

POINTS IN VENTILATION.

It was substantially a description of the fan-plan in operation at the State Lunatic Asylum, and introduced there in 1853.

It was discussed by Drs. Moore, Bell, and Castle, and then referred to the Committee on Publication.

CATARACT EXTRACTION.

DR. HERMAN KNAPP, of New York, made a brief communication upon the above operation.

Reference was made to certain technical points in the operation, consisting in a modification of Graefe's method of opening the capsule. It consisted in a horizontal section through the periphery. The results in fifty-eight successive cases were given, and were encouraging for the modification.

Communication referred to Committee on Publication.

SUPRA-CONDYLOID AMPUTATION OF THE THIGH.

DR. R. F. WEIR, of New York, read a paper upon the above subject, which will appear in a future number of the RECORD.

The paper was discussed by Drs. A. C. Post and F. H. Hamilton, and referred to Committee on Publication.

READ BY TITLE AND REFERRED.

"Biographical Sketches of Dr. E. R. Peaslee, of New York, and Dr. A. M. Vedder, of Schenectady," by Dr. F. A. Castle, of New York.

"A Communication from the Medical Society of the County of Kings, on Hygiene," by Dr. F. H. Stuart, Chairman. Referred to Committee on Hygiene.

"Milk and Lime-Water as Food and Medicine in the Neuroses," by Dr. E. N. Chapman, of Kings Co.; "Phthisis Pulmonalis," by Dr. Jas. R. Leaming, of New York; and "Obituary Notice of H. B. Salmon, M.D., of Stuyvesant Falls," by Dr. P. V. S. Pruyn, of Kinderhook.

REMEDIAL AND FATAL EFFECTS OF CHLORATE OF POTASSA.

DR. A. JACONI, of New York, read a paper upon the above subject, which was referred to the Committee on Publication. It will be published in a future number of the RECORD.

It was discussed by Dr. French.

PRESENTATION OF SPECIMENS.

DR. FISHER, of Sing Sing, presented a specimen of *cystic osteo-sarcoma* affecting the upper portion of the tibia, and also a specimen of *chylous urine*.

METRIC SYSTEM.

DR. E. SEGUIN, of New York, made a report on the metric system. He urged the adoption, by the physicians of this State, of the International Metric System, because it was a standard of uniformity in all the sciences. Although its ultimate adoption was inevitable, by postponement in the adoption of this common standard we were cut short of what was truly new in modern medicine. England was ready to adopt it, and many of the eminent physicians and chemists in this country were also ready to adopt it, and its use had also been recommended by several representative medical societies in this country.

Discussion postponed until Thursday morning.

The Society then took a recess until 7.45 p.m.

EVENING SESSION—ANNUAL ADDRESS BY THE PRESIDENT.

The Society met in the Assembly Chamber in the New Capitol, and was called to order at 7.45 by Dr. S. O. Vander Poel, of Albany.

Lieut.-Gov. Dorsheimer was then introduced, and in a pleasing address explained the two allegorical paintings.

THE PRESIDENT then delivered the annual address, having chosen for his subject,

THE RELATIONS OF THE MEDICAL PROFESSION TO THE STATE.

After a brief introduction, the subject was presented under six heads:

FIRST—AS WITNESSES TO AID IN THE DETECTION OF CRIME OR THE BREAKING UP OF NUISANCES.

It was probable that the singular contradictions of some of our medical experts had excited the wonder of laymen and a sense of shame in medical men. All intelligent laymen knew that there must always be different shades of opinion upon the same subject in a science so unsettled and progressive as our own; but nobody yet knew why it was that experts could always be found who honestly believed that no antimony ever was in a certain stomach, when it had already been discovered by supposed reliable authority, or why one man was pronounced to be raving mad by Professor A., and competent to take charge of vast estates by Prof. B. The State should summon, the State should pay experts, and they should act as associate judges, to aid the real judges in getting the truth before the jury. The medical man should be placed in a position where he might be able to treat a medico-legal case as he would a dead body under his scalpel. The subject of the adequate payment of experts came under this head, and the belief was expressed that experts should not be taken away from their ordinary duties without a compensation that would, at least to some considerable extent, recompense them.

SECOND—AS DEFENDANTS IN SUITS FOR MALPRACTICE.

It was a matter of mortification that there should be any necessity for such a relation of the profession of medicine to the State as this. But physicians were, unfortunately, not exempt from the frailties and faults of humanity, and they must expect to answer at the bar of justice for any crimes they might commit. He frankly admitted, however, in the outset, that

we ourselves were in a measure to blame for the tone of expression, about the work of physicians, which was somewhat prevalent among the people: "If Dr. — had not done so and so," or, "If he had done so and so," in the common phrase, the patient would not have died. The idea of considering the result as largely due to personal and extraordinary gifts was the basis of the notion among the laity that the attending physician was to blame if an eye was lost, a fractured limb was shortened, or if a patient died from disease. One of the remedies for unjust attacks upon the faithfulness and skill of medical men must be found in such an elevated tone of professional sentiment as would prevent us from imitating the vilest of birds, that are said to foul their own nests.

THIRD—AS EDUCATORS OF THE PHYSICIANS OF THE FUTURE.

Although from the very early history of this country the community had taken an active interest in education, and even in special education—that of ministers, lawyers, and teachers—scarcely anything had been done for the instruction of medical students, except by the individual efforts of men who elected themselves to be professors in the medical colleges which they founded. All that the State had to do with those colleges was to prescribe that students in them should study three years, that they should be twenty-one years of age when they graduated, at which time they should also be possessed of a good moral character. It was greatly to the credit of the medical colleges of this State that they had maintained medical teaching at a high standard, in spite of the indifference and the hostility which existed. Whatever might be said to the contrary, any exact examination would show that the medical teachers of the State had always been foremost in the efforts to extend sound knowledge. Apt as was the medical press to decry medical professors, it might be safely asserted that the temptations of their irresponsible position had not overcome them, but they were among the chief promoters of scientific culture. Admitting all that, there were so many evils in the present system that a change was imperatively demanded. We needed an examination for admission, a graded and fuller course, and a more rigorous final examination. He thought that, if we turned our eyes to the State of Massachusetts, we should find there the only certain measures of reforming our medical colleges. He held that the State could not undertake the work. The State, as such, however much we might ask of its individual members, should not be expected to assist, even much less, to endow medical colleges. The profession itself should secure those endowments. If educated laymen did not know that a real university should have a medical school as a part of it, we must teach them all that; then they would endow our schools. Here was the kernel of the whole matter of reform in medical education. The present necessary laxity in admissions and in final examinations fairly overwhelmed the land with physicians. But how should the heavily burdened community find means for the new call upon its benevolence? By sparing from its useless expenditures that which was here so much needed. Under this head the question of legalizing the dissection of unclaimed dead bodies was considered.

FOURTH—AS MANAGERS OF INSTITUTIONS FOR THE CARE OF THE SICK AND INJURED.

There was a widely diffused belief among business men and lawyers that physicians and clergymen had

very little of the ordinary tact necessary for the financial care of large interests. Distrust of the business and executive capacity of medical men, mingled with a notion that they were contentious, were the real reasons for the almost universal exclusion of medical men from the governing boards of hospitals and dispensaries. Put physicians in fair proportion on the boards of erection and management of hospitals, and the present condition of these institutions would soon be changed, and the system would be inaugurated in civil hospitals that had given to the medical officers of the United States army a wide and enduring fame.

FIFTH—AS PROTECTORS OF THE COMMUNITY FROM QUACKERY.

While we might not ask the State to endow medical schools, we might certainly expect that it would protect its citizens from well-defined quackery. The State could not catalogue the drugs that might be used, nor name the doses, but it could see to it that no one was allowed to prescribe for disease who had not furnished evidence of a satisfactory knowledge of anatomy, physiology, and chemistry. It should also interfere to prevent the sale of so-called patent medicines and of adulterated medicines and food. A State that would not do that, should, in all consistency, allow mad dogs to run in the streets, lunatics to go at large, and gunpowder to be stored in every house, and leave its railroad crossings without guards or signals. What was wanted was a board of examiners made up of the best men from the colleges and the profession, who should determine—not the orthodoxy of a candidate as to the doses of drugs or the uses of cold water and vegetable medicines, but as to whether he had been well grounded in the structure and functions of the human body, the remedies for poisons, the rules for action in emergencies, and the principles of diagnosis, a knowledge of which would, at least, protect his patients from scandalous malpractice.

SIXTH—AS SANITARY ADVISERS TO THE COMMONWEALTH.

That was perhaps the most comprehensive and important of any of our relations to the State. There were, however, still many obstacles, on the part of the powers that were, in the way of yielding to physicians as a class, even in matters purely sanitary. Physicians were still very largely regarded as fit only for the necessary but narrow walk of their calling—in prescribing for disease that had already broken out, and for taking charge of accidents that had already occurred. *Preventive* medicine, which we were most anxious about, was not yet fully appreciated by our lawmakers. The physician should have the same prerogative in the State as in the family. There should be a board of health in every county and in every town, and that board should have no man upon it who had not a medical, scientific, or legal education. Not a school-house, not a jail, not a hospital, not a sewer should be built unless competent sanitary advice, with power to enforce it, was given. There was also room for reform in the supervision of the hygienic condition of prisons, public charities, private and public insane asylums. There was also room for reform and work for the closing years of the nineteenth century in submitting to the tests for the perception of colors every railway and steamship official. We should follow the example of Sweden, and demand such a searching investigation as would put in other positions men whose visual defects now rendered them useless and dangerous in places where colored signals were used.

What could be done in the way of preventive medicine was perhaps nowhere better shown than in the exemption of the city of New York from cholera and yellow fever. Reference was then made to the recent epidemics of yellow fever at the South, and also to the necessity of placing medical men on the boards which had charge of our public schools.

Two things must be earnestly seen by us, if we would hasten the day when the medical profession should assume its true relations to the State. They were unity of action and a jealous regard for our reputation as a profession. With united front let us, who struggled for the prolongation of life and the mitigation of disease, continue our advance in the same column with those who, by cultivating the soil, by humane and wise legislation, and the administration of law, by the finding out of many inventions, by the inculcation of the principles of morality and religion, contended for the land and a time when "the wilderness and the solitary place should be glad for them, and the desert should rejoice and blossom as the rose," and the Eternal God should wipe all tears from the faces of men.

The address was listened to with untiring attention, and received marked demonstrations of approbation.

The Society then adjourned to meet on Thursday at 9.30 A.M.

COLLATION AT THE DELAVAN HOUSE.

After the President's address, the members of the Society and invited guests were handsomely entertained at the Delavan House, by the Medical Society of the County of Albany.

THURSDAY, FEBRUARY 6TH.—THIRD DAY.—CLOSING SESSION.

The Society was called to order at 9.30 A.M., by the President, and prayer was offered by DR. ALFRED C. POST, of New York.

On motion, the reading of the minutes was dispensed with.

DR. BAILEY, Chairman of the Committee of Arrangements, introduced DR. O. A. HORN, delegate from the Medical Society of the State of Maine, and announced the following

MEMBERS BY INVITATION.

Drs. H. R. Starkweather, Franklin Townsend, Jr., G. W. Pape, and William Morgan, of Albany, and Jas. D. Featherstonhaugh, of Cohoes.

DR. CASTLE, Chairman of the Committee on the President's Address, reported that the Society was not competent to take any action with reference to the Medical Register alluded to, and that the expense of social entertainments during the session be left in the hands of the Committee of Arrangements.

The report was adopted.

BY-LAWS OF THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

DR. WEY, Chairman of Committee on By-Laws, reported favorably on the revised by-laws of the Medical Society of the County of New York.

The report was accepted and adopted.

The report, laid upon the table yesterday, was, on motion made by Dr. Wey, taken up, amended, and adopted.

DR. KENDALL, of Onondaga, made a report as

DELEGATE TO THE MEDICAL SOCIETY OF THE STATE OF MAINE,

which was referred to the Committee on Publication.

PUBLICATION OF TRANSACTIONS.

Dr. SMITH, the Secretary, made a report from the Committee on Publication, with reference to the resolution introduced by Dr. Castle on Tuesday.

The committee recommended that no change be made in the present regulations concerning the publication of the transactions of the Society.

Dr. PIFFARD, of New York, moved that the report be adopted. He made the motion for the purpose of bringing the question before the Society, but should vote against its passage for the reason that the New York delegates had received instructions to oppose its adoption.

The question was discussed by Drs. Piffard, Wey, and Castle. The report of the Committee was adopted by a rising vote—ayes, 43; nays, 19.

METRIC SYSTEM.

Dr. F. A. CASTLE, of New York, introduced a resolution asking the State Medical Society to request all who might present papers at future meetings of the Society, to employ the metric system in their writings, and that the metric system should be exclusively used in the published proceedings of the Society. Adopted.

PRESIDENT'S ADDRESS.

Dr. A. N. BELL, of Brooklyn, moved that 5,000 copies of the President's Address be printed and distributed to the physicians in the State, the members of the Legislature, and the members of the State Government. He urged it as a measure to benefit public sanitation. Adopted.

SUPPRESSED MINUTES.

Dr. PIFFARD moved that the Committee on Publication be directed to include in the next volume of the Transactions the suppressed minutes of the meeting held Feb. 1, 1876.

Dr. WEY remarked that he was not competent to vote upon the motion, and asked for a brief explanation.

Dr. PIFFARD explained by saying that a meeting was held Feb. 1, 1876, and that the minutes of that meeting had not been published. The object of his motion was to secure their publication.

THE SECRETARY said he knew of no minutes of such a meeting, except that some twenty-two names were registered as having attended it. He supposed the meeting was held, if held, to make sure that there was no illegality concerning subsequent stated meetings.

Dr. WEY moved that the matter be referred to the Committee on Publication, with power.

Dr. FRAZIER, of Oneida Co., remarked that it was most singular that these queer questions should arise for action by the country members. First, a resolution was offered that no transactions at all be published; in a few moments a resolution was offered relating to their publication; at one moment there were journals sufficient for all purposes, and at the next moment our transactions were vastly important, and the next moment they were good for nothing, and he moved to lay the whole subject on the table. Carried.

Dr. CASTLE moved that an adjourned annual meeting be held in the city of New York in October, at which no business should be transacted except the reading and discussion of scientific papers.

Dr. KENDALL moved to lay the subject upon the table. Carried.

AUDITING COMMITTEE.

The President appointed Drs. Piffard, N. C. Husted, and E. C. Lyman, as a committee to audit the Treasurer's Report.

SURGICAL USES OF THE ACTUAL CAUTERY.

Dr. A. C. POST, of New York, read a paper upon the above subject, which will appear in a subsequent number of the RECORD.

Dr. HUSTED, of the Auditing Committee, reported that the account of the Treasurer had been examined, found correct, and was approved by the Committee.

The report was accepted and adopted.

CAVERNOUS ANGIOMA OF THE TONGUE.

Dr. E. R. HUN, of Albany, presented a paper upon the above subject, which was read by title, and referred to the Committee on Publication. He also presented the patient and the portion of tongue removed. It was removed by means of the Cerasour, twenty-seven minutes being consumed in the operation. Speech and ability to eat were restored.

WRITER'S CRAMP.

Dr. G. M. BEARD, of New York, gave the conclusions from an analysis of one hundred cases of writer's cramp and allied affections.

The conclusions will be published in a future number of the RECORD.

THE INFLUENCE OF THE OPTICAL CONDITION OF THE EYE UPON THE DEVELOPMENT OF CHARACTER.

Dr. E. G. LORING, of New York, read a valuable paper upon the above subject, in which he urged the importance of correcting optical defects, such as near-sightedness, long-sightedness, and astigmatism, before the education of the child was commenced. The conclusion reached by him was that the eyes of every child should be carefully examined before entering any school, and that the Legislature should pass a law compelling an examination of the eyes before the child was permitted to enter our public schools. The paper was referred to the Committee on Publication.

ON THE ADIRONDACK REGION IN THE TREATMENT OF PULMONARY PHTHISIS.

Dr. ALFRED L. LOOMIS, of New York, read a paper upon the above subject, which will be published in a future number of the RECORD.

ELIGIBILITY TO PERMANENT MEMBERSHIP.

THE SECRETARY remarked that it had been the custom when a person, eligible to permanent membership, removed from one district to another, to transfer his name to the list of those eligible to permanent membership from the district to which he removed. He asked for an opinion from the Society with reference to the correctness of the procedure. The Society endorsed the custom.

SALARIES OF THE SECRETARY AND THE TREASURER.

Dr. SQUIBB offered a resolution providing for an increase of the salary of the Secretary to \$350, and that the Treasurer be allowed \$100. Adopted.

REPORT OF COMMITTEE ON NOMINATIONS.

Dr. C. A. ROBERTSON, of Albany, read the following report:

For President—Dr. Henry D. Didama, of Syracuse, Onondaga County.

For Vice-President—Dr. Nathaniel C. Husted, of New York.

For Secretary—Dr. Wm. Manlius Smith, of Manlius, Onondaga County.

For Treasurer—Dr. Chas. H. Porter, of Albany.

For Censors—Southern District: J. W. S. Gouley, of New York; George J. Fisher, of Sing Sing; and Edward H. Parker, of Poughkeepsie. *Eastern Dis-*

trict: John P. Sharer, of Little Falls; Norman B. Snow, of Albany; and E. D. Ferguson, of Troy. *Middle District*: M. M. Bagg, of Utica; Geo. W. Cooke, of Otego; and Chas. G. Bacon, of Fulton. *Western District*: C. C. Wycoff, of Buffalo; Harvey Jewett, of Canandaigua; and E. V. Stoddard, of Rochester.

Committee on Correspondence—*First District*, T. A. Emmet, of New York; *Second District*, D. Guernsey, of Amenia; *Third District*, R. H. Ward, of Troy; *Fourth District*, T. B. Reynolds, of Saratoga; *Fifth District*, S. G. Wolcott, of Utica; *Sixth District*, J. G. Orton, of Binghamton; *Seventh District*, H. B. Wilbur, of Syracuse; *Eighth District*, C. E. Rider, of Rochester.

Committee on Prize Essays—W. W. Ely and E. M. Moore, of Rochester; and T. F. Rochester, of Buffalo.

Committee on By-Laws—Wm. C. Wey, of Elmira; Wm. Manlius Smith, of Manlius; and Wm. H. Bailey, of Albany.

Committee on Publication—J. P. Dunlap and Alfred Mercer, of Syracuse; Wm. Manlius Smith, of Manlius; and Chas. H. Porter, of Albany.

Committee on Hygiene—E. V. Stoddard, of Rochester; J. G. Orton, of Binghamton; D. Guernsey, of Amenia; C. R. Agnew, of New York; M. H. Burton, of Troy; E. Hutchinson, of Utica; and Harvey Jewett, of Canandaigua.

Permanent Members—*First District*: Horace P. Farnham and Wm. T. White, of New York; Arthur Matthewson and J. S. Prout, of Brooklyn. *Second District*: John Davidson, of Hempstead, Queens County, and Geo. C. Smith, of Rondout, Ulster County. *Third District*: B. A. Mynderse, of Schenectady, and Walter B. Chase, of Windham, Greene County. *Fourth District*: Asa W. Tupper, of North Granville, Washington County, and Z. B. Bridges, of Ogdensburg. *Fifth District*: A. S. Coe, of Oswego, and J. Mortimer Crawe, of Watertown. *Sixth District*: C. H. Stiles, of Owego, Tioga County, and M. L. Bennett, of Watkins, Schuyler County. *Seventh District*: Theodore Dimon, of Auburn. *Eighth District*: William Ring and John Cronyn, of Buffalo.

Honorary Members—L. Auguste Mercier, of Paris, France; Christopher Heath, F.R.C.S., of London, England; Henry J. Bowditch, of Boston, Mass.; and Greenville Dowell, of Galveston, Texas.

Eligible to Honorary Membership—W. S. Teevan, F.R.C.S., of London, England, and Gen. Joseph B. Brown, U. S. Army, North Tarrytown.

DELEGATES

To the Medical Society of the State of Pennsylvania—Joshua B. Graves, of Corning.

To the Massachusetts Medical Society—J. L. Banks and H. P. Farnham, of New York, and P. R. H. Sawyer, of Bedford, Westchester Co.

To the Connecticut Medical Society—A. T. Douglass, of Rondout, H. D. Noyes, of New York, and J. C. Hutchison, of Brooklyn.

To the Medical Society of New Jersey—N. C. Husted and Robert Newman, of New York; William Govan, of Stony Point, and J. C. Hutchinson, of Brooklyn.

To the Vermont State Medical Society—A. J. Long, of Whitehall, Washington Co.; W. W. Porter, of Syracuse, Onondaga Co., and L. Barton, of Williamsborough, Essex Co.

To the Rhode Island Medical Society—James C. Hutchinson, of Troy.

To the Missouri State Medical Society—J. R. Boulware, of Albany.

To the Illinois and Iowa State Medical Societies—J. Kneeland, of Onondaga.

To the Medical Society of the State of Ohio—Thos. R. Pooley, of New York.

Censor for the College of Medicine of Syracuse University—Jas. S. Bailey, of Albany.

Delegates to the American Medical Association—H. R. Ainsworth, Addison; S. G. Wolcott, Utica; C. C. Wycoff and Thos. F. Rochester, of Buffalo; J. M. Minor, J. H. Hinton, and J. W. S. Gouley, of New York; J. C. Hutchison, of Brooklyn; D. B. St. John Rbosa, of New York; Albert Van Derveer and Chas. A. Robertson, of Albany; Stephen Smith and F. H. Hamilton, of New York; John P. Gray, of Utica; A. C. Post and H. D. Noyes, of New York; Wm. C. Wey, of Elmira; Frederick Hyde, of Cortland; E. H. Parker, of Poughkeepsie; Theodore Dimon, of Auburn; E. M. Moore and W. S. Ely, of Rochester; P. R. H. Sawyer, of Westchester Co.; H. D. Didama, of Syracuse; Thos. M. Johnson, of Buffalo.

Before the reading of the report, Dr. Squibb remarked that the Committee believed it to be proper to drop the Committee on Pharmacology, allowing it to be replaced by the delegation to the Convention for Revising the U. S. Pharmacopœia, in 1880.

It was also the opinion of the committee that a delegation consisting of twenty-five, instead of thirty-seven members, was sufficient to represent the Society in the American Medical Association.

The report was accepted and unanimously adopted.

REPORT FROM THE COMMITTEE ON BY-LAWS—ILLEGALITY OF A BY-LAW ENACTED IN 1872.

DR. WEY, Chairman of the Committee on By-Laws, reported with reference to the legality of a by-law enacted in 1872, concerning medical students, that, after consulting two of the judges of the Court of Appeals, the conclusion was reached that the by-law was *illegal*, and that neither State nor county societies were empowered to take such action as indicated in the by-law enacted.

The report was adopted.

On motion, the illegal by-law was rescinded by the Society.

TRAUMATIC ORIGIN OF SUBFASCIAL, DEEP-SEATED, OR COLD ABSCESS, COMMONLY CALLED CONSTITUTIONAL OR SCROFULOUS ABSCESS.

DR. LEWIS A. SAYRE, of New York, read a paper upon the above subject, which will appear in a future number of the RECORD.

It was briefly discussed by Drs. E. M. Moore, of Rochester, and A. L. Loomis, of New York, and referred to the Committee on Publication.

WARM WATER IN THE TREATMENT OF TRAUMATIC GANGRENE.

DR. F. H. HAMILTON, of New York, related his latest experience in the use of hot water in the treatment of traumatic gangrene. It was favorable to the agent employed.

DR. E. M. MOORE, of Rochester, regarded the plan of treatment brought forward by Dr. Hamilton as one of the greatest advances in surgery.

PAPERS READ BY TITLE AND REFERRED TO THE COMMITTEE ON PUBLICATION.

"Eserin and Pilocarpin in Ophthalmic Therapeutics," by C. S. Bull, M.D., of New York.

"On the Use of Water in the Treatment of Diseases of the Skin," by L. D. Bulkley, M.D., of New York.

"Report of Delegate to the Medical Society of the

State of New Jersey," by H. S. Crandall, M.D., of Madison Co.

"On the Value of Carbolized Animal Ligature Applied Antiseptically in the Treatment of Ancurism," by Stephen Smith, M.D., of New York.

"Obituary Notice of Joseph Northrup, M.D., of Albany," by F. C. Curtis, M.D., delegate from the Albany County Medical Society.

"Ulcerative Phthisical Laryngitis: Value of Tracheotomy in its Treatment," by Beverley Robinson, M.D., of New York.

"Report of Nine Cases of Uterine Fibroids, with Remarks," by A. Van Derveer, M.D., of Albany.

"Causes of Death during Surgical Operations," by A. L. Ranney, M.D., of New York.

On motion, made by Dr. Hutcheson, of Brooklyn, the thanks of the Society were unanimously tendered to the Capitol Commissioners for the use of the old Assembly Chamber during the meeting, and for the use of the new Assembly Chamber on Wednesday evening.

The President thanked the Society for the uniform courtesy extended to him by the Society, and declared the Society adjourned to meet in Albany on the first Tuesday in February, 1880.

Correspondence.

THE PUBLIC HEALTH ASSOCIATION AND NATIONAL ACADEMY OF SCIENCES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your issue of the 1st inst., there are some editorial remarks regarding the Withers bill, which is supposed to embody the views of the American Public Health Association as to what the National Health Commission should be, which are capable of conveying impressions that are not the facts of the case.

It is stated, in referring to the memorandum furnished by the Public Health Association, as follows: "It is further urged, in the memorandum of the Health Association referred to, that the selection of a committee for this purpose is of the greatest importance, and that consequently it should be left to the members of the National Academy of Sciences. Probably as an improvement on this suggestion, the said Academy was designated in the bill as the proper body to take the matter in hand. We cannot believe that the Public Health Association is willing to father the bill as it now stands—to leave sanitary matters to a body of gentlemen who have never given any attention to the subject, and whose studies are confined to astronomy, geology, entomology, and kindred subjects."

The very solicitude which was felt by the Association that the appointment of the sanitarians to compose the National Health Commission should not be influenced by "political or local" considerations, caused the Public Health Association to adopt this mode of selecting the men.

The language used in the memorandum prepared for general information is as follows: . . . "After careful consideration of various plans proposed to secure this end, which is felt by all to be vitally necessary to success, we are of opinion that the simplest and surest method, and one which will command the most general approval among the scientific and

professional men of the country, is that Congress should request the National Academy of Sciences to designate the members of the Commission."

There are, it seems, legal or constitutional reasons why Congress cannot, in its prescribed powers, be aided by the wisdom of the National Academy in its knowledge of men, so as to designate those whose acknowledged ability would meet universal approval. In section six of the memorandum, which suggests this manner of appointing the Commission, this difficulty is referred to.

The Public Health Association could not properly mention any of their own number as those who should be appointed members of the Commission, although there are many without doubt richly qualified, and sought the aid, through Congress, of the National Academy, so that the President of the United States might be furnished with a list of names of men who are distinguished by their labors, of ability and success in sanitary science, and from this list the members of the Commission should be chosen.

If the President cannot be advised by the National Academy regarding the appointment of persons to positions, the duties of which, to be properly discharged, require that those holding them shall have special scientific qualifications, from what unprejudiced source shall he receive this information?

Sanitary science will probably never be absolutely separated from that of medicine; yet it is no less true that the investigation of causes of disease, is, at the present moment, within the field of labor of those gentlemen composing the National Academy.

Perhaps we will not disagree in the opinion that were the whole matter of sanitary supervision of the United States turned over to the National Academy, its success would suffer less violence than were the selection of the Commission entrusted to purely political managers. I have no doubt, should any law be passed delegating these matters to the Academy, the gentlemen composing that corporate body would act with becoming wisdom. Professor Simon Newcomb, for instance, would not attempt to investigate the causes of yellow fever or diphtheritis from the Observatory in Washington, by observations through his large telescope!

Trusting that I have shown that the sole object that the Public Health Association had in view was to secure men highly qualified for the duties required of them,

I am, very respectfully,

B. F. GIBBS,

*Medical Inspector U. S. Navy, and Member Advisory
Committee Public Health Association.*

WASHINGTON, D. C., Feb. 5, 1879.

[So far as the facts of the case are concerned, we agree perfectly with our esteemed correspondent. We certainly meant what we said in the paragraph quoted, and we fail to see how we could convey an erroneous impression. The Public Health Association did ask that the National Academy of Sciences should name the members of the Commission, and it is not disproved that the Withers bill leaves the whole matter virtually in the hands of the aforesaid Academy. It is well enough for the Association to place the appointments beyond the reach of politics; but with due deference to the arguments of Dr. Gibbs, we still object to the course suggested. We are so confident that it will not meet with "the most general approval among the scientific and professional men of the country," that we are willing to risk a reiteration of our protest.—Ed.]

PROF. STILLÉ AND ACUTE ARTICULAR RHEUMATISM.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the lecture on "Acute Articular Rheumatism," by Prof. Stillé (MEDICAL RECORD, Jan. 18, page 50), he says: "I desire to lay great stress upon the statement that the treatment of simple acute articular rheumatism may be abandoned to palliatives and nature." "No treatment was ever invented which stopped a case of acute articular rheumatism."

In a practice of fifteen years, three of which were in the army, I have had some experience in this disease. I have had the pleasure of listening to a course of lectures by Dr. Austin Flint, and have heard him make the statement quoted, and I must say that my experience leads me to differ from both these gentlemen. Were I suffering from the disease as I have have seen others suffer, I should hardly be content to be left to palliatives and nature, fully persuaded as I am by abundant testimony in THE MEDICAL RECORD and other journals, as well as some experience of my own, that we have in salicylic acid and its salts a remedy which will frequently, to say the least, cut short the attack, and that speedily.

I started out with the notion, Dr. Watson's, I think: "Rheumatism, well treated, runs seven weeks; not treated at all, it runs forty-nine days." I now think that such teaching is erroneous and mischievous. I believe that the physician is culpable who does not cure the majority of cases of simple acute rheumatism in less than two weeks, and who does not cure many in less than one week; and I believe that under the administration of salicylic acid there will generally be decided and permanent improvement in two days.

In subacute cases, especially in a malarial climate, salicin is very efficient.

CASES.—L. H., mulatto, aged 25, had been at Union Depot, St. Louis, about a month washing floors and windows; seized with acute rheumatism Jan. 25th. I saw him the 28th, in the evening. He was on his back in bed; right knee much swollen, and so painful that he had not been able to get any rest night or day. On my approaching him he was very fearful lest I should touch it. He had not slept the night before, and said he was getting worse and worse; begged me to give him something to relieve the pain and make him sleep. I gave him a dozen ten-grain powders of salicylate of soda, with directions to take one every two hours till he was better; then every four hours.

Jan. 29.—Better; can move knee; slept well the night before; felt better after taking the second powder; had taken eight powders; was now taking them every four hours.

Jan 31.—Wants to get up; says he can walk as well as I can; says the powders acted like magic.

And yet "No treatment was ever invented which stopped a case of acute articular rheumatism."

May 28, 1877.—Mrs. H., aged 35; acute rheumatism; high fever, great pain and swelling in arms and legs, shoulder and knee. As in the other case, pain so great as to prevent sleep. Ordered salicylic acid, twenty grains every two hours, with enough bicarbonate of soda to render it soluble in water, till better, then three times a day. Called again May 30th, and found her in the act of springing into bed as I approached her room. She slept well the first night after taking the medicine. From imprudence she had a slight return, but the same treatment promptly relieved her.

In one case, a severe one, of a young farmer, I thought I did well to get him out of his bed and able

to work in three weeks, under the use of the alkaline treatment with electricity.

In no case have I seen even slightly bad effects from salicylic acid, although, in one case, I administered nearly an ounce in less than four days. Its action is prompt in relieving the pain and reducing the fever. In no case, when using it, have I found external applications necessary.

B. J. BRISTOL.

WEBSTER GROVES, ST. LOUIS CO., MO.

SNAKE IN THE EYE OF A HORSE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Doctor Charles J. Kipp, of Newark, N. J., has given in a recent number of THE MEDICAL RECORD a very interesting account of "A Filaria in the Eye of a Horse," as seen by him and operated for a year ago in said city. It recalls to my recollection a similar account read by me a long time previously, in the Transactions of the American Philosophical Society, Vol. II., published in Philadelphia, 1786. The account was contained in a monograph entitled "Of a Living Snake in a Living Horse's Eye, and of Other unusual Productions of Animals," read before the Society June 5, 1782, by John Morgan, M.D., F.R.S. London, Professor of the Theory and Practice of Physic, Philadelphia. The author, after some extended remarks upon the subject of equivocal generation, apologizes for the interest he took in the phenomena he was describing; professes his want of credulity and his little liability to be lumbugged, and insists that he could not be deceived as to the reality of the object he describes. He claims that "from the closest ocular examination, with unwearied attention, repeated more than once, he conceives he is not mistaken in asserting that there is a real snake in the eye, which, from the vivacity and briskness of its motion, exceeds that of any worm, and equals that of any kind of serpent he has ever seen." The horse alluded to was on exhibition in Philadelphia in Arch street, between Sixth and Seventh streets, as a great curiosity, and was advertised in the Pennsylvania Gazette, May 23 (1782), and is described by Dr. Morgan as follows:

"The horse in whose left eye this extraordinary *lusus natura* is visible, is of a sorrel color, nine years old; it belonged to Dr. Dayton, near the lines at Elizabethtown, and, I am told, appeared to have no uncommon appearance in either eye till within a few months ago. The first particular circumstance which excited the owner's attention was, that having lent him to a friend to take a ride in a chair, although it was not known to be vicious or unruly before, it could not now be kept under any government, but ran away with, and dashed the chair to pieces. The right eye still continues in a sound state. Soon after, viz., about ten weeks ago, Mr. Richard Wells, merchant, of this city, a gentleman of probity and of great philosophic knowledge, being at Elizabethtown in company with Dr. Dayton, this gentleman told him he would show him a curiosity as great, perhaps, as he had ever seen, namely, a living snake in a living horse's eye. Mr. Wells then desiring to see it, upon looking into the eye, discovered the animal very plainly, in a constant serpentine motion, but necessarily in a somewhat convoluted form, as its length was equal, as nearly as he could judge, to two diameters and a half of the eye, which could not measure less than between three and four inches. The head and tail, or, if you please, the two extremities of the animal, were then visible, and the horse's eye still retained its transparency enough to

admit seeing the whole of the snake distinctly. The horse was soon after purchased by a free negro to bring to Philadelphia for show. At present, apparently, from the brisk and almost constant motion of the animal, which is somewhat increased in length since the inspection at Elizabethtown, and which is as thick as a knitting-needle or piece of common twine, as nearly as can be determined through the intervening medium, the aqueous and vitreous humors of the eye are confounded (the fine cellular texture of the latter being broke down), and tinged with the softest part of the crystalline, so as to assume somewhat of a white milky appearance, bordering on the color of a cataract. The iris appears to be greatly dilated, or rather wholly destroyed. For the septum or partition which separates the anterior from the posterior chambers in a sound eye, must be broken down, as the animal, or, to speak like a septic, the animal appearance of a snake is continually receding into the fundus and back part, and by times coming forward into the anterior part of the eye, with a convoluted brisk motion. I cannot think a snake of the same size, moving briskly in a tumblerful of fair water, or of water discolored with a teaspoonful of milk, would be more visible; but the coats of the eye and humors have now somewhat of a milky appearance, or color of an incipient cataract."

He concludes the horse is blind in the affected eye—the lids of it being closed, and only opened on striking the horse smartly on the back with the open hand. The medical faculty were nonplussed by the phenomena, and at a loss to account for the appearance on common principles or from known diseases. The great question with them was, if it were a real snake or living animal, how did it get into the horse's eye?

Thinking that from the rarity of the phenomena as described by Dr. Kipp, and that Dr. Morgan's case was doubtless the first observed in this country, it might prove of sufficient interest, I transcribe it for the columns of THE MEDICAL RECORD.

R. S. SWORDS.

NEWARK, N. J., 3d February, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 26 to February 8, 1879.

OLEAGINOUS SOLUTIONS OF CHLORAL.—Chloral hydrate is soluble in two parts oil, says M. Chatillon (*Gaz. Hebdom.*). He recommends: B. Chlorali, part. vj.; ol. amygdal., part. xxx. M. Or B. Chlorali, part. vj.; cere, part. ij.; adipis, part. xxvij. M. And B. Chlorali, part. j.; cere alb., part. ij.; ol. theobrom., part. ijss. M. Ft. suppositoria.

NEW YORK ACADEMY OF MEDICINE.—The credit should be given to a member of the medical profession and not simply to a private citizen, for the donation of \$5,000, noticed in the last number of the RECORD (see p. 136).

In the case reported by Dr. Barker (see p. 140) the sentence, "The woman became pregnant and went to the full term of utero-gestation twice," should be omitted.

Obituary.

JACOB BIGELOW, M.D., LL.D.

JACOB BIGELOW, M.D., LL.D., distinguished as a practitioner, teacher, and writer since the commencement of this century, died in Boston, Mass., on January 10th, at the age of 91 years. He was born in Sudbury, Mass., in 1787, was graduated at Harvard University in 1806, and commenced practice in Boston in 1810. He early became known as a skilful botanist, having an extensive correspondence with botanists in Europe, and several plants were named for him by Sir J. E. Smith in England, by Schrader in Germany, and in France by De Candolle. In 1814 he published "Florula Bostoniensis," to this day the most complete work of its kind, and a standard authority. In 1815 he published "American Medical Botany," in three volumes, octavo, illustrated by colored plates, after nature—one of the most beautiful productions of the American press. At this period he occupied the chair of Materia Medica in Harvard Medical College, and also that of Clinical Medicine; was an active practitioner in Boston for forty years, enjoying a large and lucrative practice; also for a long period physician to the Massachusetts General Hospital. From 1816 to 1827 he delivered lectures "On Application of Science to the Useful Arts," which resulted in the establishment of the "Institute of Technology."

In 1820 he was one of the "Committee of Five" selected to form the American Pharmacopœia: and the nomenclature of the Materia Medica (afterwards adopted by the British College), substituting (when practicable) a single for a double word, is due, in principle, to him. He also published numerous medical essays and discourses, some of which are to be found in a volume entitled "Nature in Disease." One of these, "Discourse on Self-Limited Diseases," has had great influence in modifying the practice of physicians since that time in regard to the treatment of acute diseases. His conservative mind exercised a healthy restraint in accepting, with caution, new theories on the action of drugs.

In 1854 he was elected Corresponding Fellow of the New York Academy of Medicine. Dr. Bigelow was the founder of Mount Auburn Cemetery, the first of its kind in the United States, and model of all other cemeteries which have followed. The stone tower, chapel, gates, and fence were designed by him. The colossal Sphinx, in granite, was his final gift, and will forever remain a suitable monument to his public spirited labors.

For many years he was President of the Massachusetts Medical Society, and of the American Society of Arts and Sciences. In 1856 the trustees of the Massachusetts General Hospital placed his bust, in marble, in their hall, in commemoration of his long-continued services.

In the last years of a life protracted long after the period allotted by the Psalmist, his failing strength prevented exercise, and his loss of sight rendered him helpless, but his mental faculties retained a portion of their early vigor until within a short period prior to his decease.

He was the oldest member of the Massachusetts Medical Society, and one of a group of prominent men whose lives are intimately connected with the early history of medicine in our country. The names of Nathan Smith, John C. Warren, James Jackson, and Jacob Bigelow, will long live in the annals of

our profession. The name of Bigelow is worthily perpetuated in his son, Henry J. Bigelow, M.D., surgeon to the Massachusetts General Hospital, etc. Dr. Bigelow was a most laborious worker, a skilful physician, a public-spirited and estimable citizen. He regarded the calling of the physician as a sacred vocation and the "noblest of all arts." He did not pursue it as a trade, for self-aggrandizement and wealth, but for the relief of suffering humanity. He was a man of refined taste, and the sketches illustrating his beautiful botanical works were from his own designs. As a lecturer he was fluent, his powers of illustration clear. To his juniors he was ever kind, and, to the last, modest, ingenuous, and benevolent. His character is one which it is a pride to record, a pleasure to recall, a profit to imitate. Well saith Rome's greatest orator, "Brief is the time, short is the space allotted to man upon earth; but the memory of a life nobly rendered is immortal." J. G. A.

THE AMERICAN JOURNAL OF OTOLOGY.—We have received the first number of this new journal, published by Messrs. William Wood & Co. It is edited

by Clarence J. Blake, M.D., of Boston, in conjunction with Prof. A. M. Mayer, of Hoboken; Drs. Albert H. Buck and Samuel Sexton, of this city; Dr. C. H. Burnett, of Philadelphia; Dr. J. Orne Green, of Boston; and Dr. H. N. Spencer, of St. Louis. This new venture will be devoted to the interests of physiological acoustics and aural surgery. In the introductory note the editor alludes to the remarkable increase which the past ten years have seen in the interest in the study of the laws which govern the production and propagation of sonorous vibrations, and correspondingly in the study of the structure, functions, and diseases of the complicated apparatus which enables us to appreciate that mode of motion to which we give the name of sound. This interest, which has received a new impetus by the inventions of the telephone and phonograph, suggests to the aural surgeon the necessity of over-stepping what has usually been considered the boundary of his professional province, by turning his attention to investigations in physics as the ground-work of his physiological and pathological studies, in order that he may be the better qualified to make that practical application of the knowledge to be so acquired in the conservative treatment of the various diseases of the human ear.

The number also contains the following original papers: "Twenty Cases of the Growth of Aspergillus in the Living Human Ear," by C. H. Burnett, M.D. (a continued paper of considerable practical importance and interest); "Syphilitic Affections of the Ear," by Albert H. Buck, M.D. (with a report of 21 cases); "The Use of Calcium Sulphide in the Treatment of Inflammation of the External Auditory Meatus," by Samuel Sexton, M.D., a capital and practical article. Then follow "Book Notices" (11 pages), and abstracts of papers (25 pages). If future numbers preserve the present standard of excellence, the success of the journal is assured. Being royal octavo, and printed in large clear type on heavy paper, each year's numbers will form a beautiful volume.

SLIPPERY-ELM BARK IN TAPE-WORM.—Eat large quantities of slippery-elm bark for several days, and follow with a castor-oil and turpentine emulsion. The entire worm, head and all, will be passed enveloped in the undigested slippery-elm bark, which seems to entangle the worm so as to cause it to lose its hold upon the intestines.

DIAGNOSIS OF ALCOHOLIC COMA.—Dr. Macewen, of the Royal Glasgow Academy, lays down the rule that an insensible person who, being left undisturbed for from ten to thirty minutes, has contracted pupils, which dilate when the person is shaken, without any return of consciousness and then contract again, is suffering from alcoholic coma.

UNGUENTUM VASELINI PLUMBIUM.—Highly recommended by Prof. Kaposi, of Vienna, as a substitute for the *diachylon ointment* of Hebra, is prepared by heating equal parts of *emplast. diachyl. simp.* and vaseline together.

OUR esteemed contemporary, the London *Lancet*, gives (Nov. 30th) its readers a fine woodcut of a profile view of the bust of Harvey, which exists in the Harvey chapel, Hempstead, England. This profile view was drawn by the eminent Mr. Woolner, for Dr. B. W. Richardson, of London, and, it is claimed, gives the best representation of the face of the great anatomist extant.

DR. LOMBE ATTHILL, Master of the Rotunda Lying-in Hospital, has been elected an honorary member of the Gynecological Society of Boston.

EVOLUTION AND HUMAN ANATOMY.

By STANFORD E. CHAILLÉ, A.M., M.D.,

PROF. PHYSIOLOGY AND PATH. ANAT., MED. DEPT. UNIV. LA.

"In the place of miracle, natural science has substituted law."

THE "Descent of Man" closes with the once startling assertion, that "man still bears in his bodily frame the indelible stamp of his lowly origin." If this be true, then man's conception of an ever-loving and all-merciful God would be based on a benevolent reality, rather than on a malevolent fiction; since man would belong to a risen, not to a fallen race, and should exchange a discouraging belief in his degradation from a perfect parent for an encouraging faith in his own progressive development.

No one familiar with the history of the warfare between science and religion will be deterred from investigating the proofs of Darwin's assertion, though it is denounced by biblists as "evidently contrary to Scripture;" for, such denunciations recall the history of many similar contests, of which three, at least, cannot, for the good of mankind, be too often repeated.

The rotundity of the earth was denounced for centuries "as contrary to Scripture,"* and the believers thereof were cursed and punished as "heretics, infidels, and atheists"—until Magellans, sailing ever in one direction, returned in 1519 to his point of departure.

The Copernican doctrine—that the planet of vain-glorious man was not the centre of the universe, but that the sun was the centre of our system, and that the earth moved around this centre, not the sun around the earth—was declared, in 1616, by the Cardinals of the Roman Inquisition, to be "absurd, heretical, and contrary to Holy Scripture." The great book, which, in 1543, first taught this now familiar truth, was condemned to remain on the Roman "Index Librorum Prohibitorum" from 1616 to 1820. For advocating this truth, Bruno was burned, Campanello tortured, Galileo terrified into perjury; and Luther and Melancthon joined hands with the Pope, uniting Protestantism to Catholicism in upholding as scriptural† the woful ancestral errors, to the overthrow of which Copernicus and Galileo owe their undying fame.

For centuries the creation of "the heavens and the earth" within six days‡ was an article of religious faith requisite to man's salvation. Even in 1850 the great Christian scientist, Agassiz, deemed it necessary in his geological lectures at Harvard, to explain and apologize to an audience of college-boys, for teaching that the works of the Creator buried in the bowels of the earth testified irrefutably that it could not have been made within six days; and to defend himself against the maledictions hurled against him by that pulpit and press, which accepting at last the lesson once fiercely denounced, now uses his great, but at one time execrated name, to wage an equally hopeless battle against the doctrine of evolution. The only doctrine which explains to the biologist the Creator's mode of action in accord with such well-known facts as: that useful animals are burdened with useless organs, and harassed by other animals, useless and noxious;

that organs and organisms are modified by, and are adapted to the varying conditions of existence; that use causes development, disuse the atrophy of organs, and thus new organisms may appear, while old ones may disappear; and that nature's work is done through laws simple, uniform, and constant.

It would be presumed, that the marks of man's lowly origin, stamped indelibly upon his bodily frame, should be familiar to, at least, physicians, since they are forced to study human anatomy. But, in truth, few physicians, even though skillful anatomists, are well informed on this subject, for the reasons, that they pursue anatomy for practical purposes, not for philosophical deductions; that they study superficially, if at all comparative anatomy, on which depends the significance, so far as evolution is concerned, of human anatomy; and that the indelible marks of man's lowly origin are to be found chiefly in three directions, of little importance to, and, therefore, little studied by the medical anatomist. These three directions are: the anatomy of the human being while within the womb—embryology; the anatomy of bodies deviating from the common rule— anomalies; and the anatomy of certain parts—rudimentary organs—imperfect in and useless to man, but perfect in and useful to lower animals. In these three neglected departments of anatomy will be found in abundance the indelible marks of man's lowly origin. Some of these will now be presented under the headings: Embryology, Anomalies, and Rudimentary Organs; however, every example presented will not be strictly confined to its appropriate heading, because the three subjects are so related that often an example of one is strengthened when united to an example of the other. This close relationship is so marked between embryology and anomalies, that the classification of monstrosities, which are simply gross and hideous anomalies, is based upon embryology.

EMBRYOLOGY.

If the different stages of man's development within the womb be not a synopsis or recapitulation of his genealogy during the enormous duration of terrestrial life—then these progressive stages are not only inexplicable, but also are so deceptive as to suggest the same explanation, once current as to fossils—that they were "deceptions of the devil."

Man, "in action, how like an angel! in apprehension how like a God! . . . the paragon of animals," originates, not, as our ancestors taught, from a homunculus or diminutive baby, but from a little ovule or cell, as does a fish, frog, snake, bird, and dog; it is about $\frac{1}{16}$ inch in diameter, and apparently differs in no respect from the ovules of other mammals. In the hatching of this microscopic egg it successively presents in striking particulars the same forms of animal life disclosed in the successive strata of geology, and taught in our school-books as the five progressive steps from the lowest to the highest vertebrates; for, the human embryo, at first invertebrate, subsequently assumes, in many things, the organization of a fish, an amphibian, a reptile, and a mammal, while becoming man-like—and yet has never ceased to be a human being. At the third week of hatching, this future man is a gelatinous worm-like body, and even at the eighth week can scarcely be distinguished from the embryo of a dog. Among the details of this gradual development, the following deserve attention; but, to appreciate them, a comprehension of some facts in the development of lower animals is indispensable:

An egg, to grow, must, like every living thing,

* See Is. xl. 22; Ps. lxxiv. 17; cxxxv. 7; Jer. ii. 16; Rev. vii. 1.

† See Josh. x. 12, 13, 14; Mal. i. 11; Ps. civ. 19; ex. ii. 3; Is. xxxviii. 8; Re. i. 5; Hab. iii. 11.

‡ See Gen. i. 31; ii. 1, 2.

have air, water, and food for nutriment. How are these supplied? In all vertebrates, blood-vessels, always the conveyers of nutriment, sprout from the microscopic embryo within the yolk or vitellus, and, extending over its surface, form a "vascular area," which conveys to the embryo all such nutriment as the water or air outside of this area may bring in contact with it, and also the nutritious yolk inside of this area: as the embryo thus consumes the yolk, this constantly diminishes, so that the vascular area gradually becomes a sac, which is called the "umbilical vesicle." The blood-vessels constituting first the vascular area, then becoming the vessels of the umbilical vesicle, form what is called the vitelline circulation, which, though the primary circulation of every vertebrate, is transient, disappearing by atrophy as soon as the yolk has been consumed, and other organs have been developed to supply the ever indispensable air, water, and food. This vitelline circulation supplies with nutriment the embryo of a fish, and of its brother frog, until converted into a minnow or a tadpole, when the sufficiently developed alimentary canal, and gills or branchiæ provide the requisites for additional growth.

The egg of a bird and of a reptile is at first nourished by the same vitelline circulation which suffices to convert an embryonic into a perfect fish; but, long before the hen's egg becomes a chicken, this primary circulation begins, inexplicitly to the special creationist, to disappear, while two new organs are developed—the amnion, with the more important allantois, which supply the embryonic bird and snake with a *secondary* circulation, in place of the disappearing *primary* one of the fish and frog. Thus, the hen's egg is provided with air and food until it becomes a chicken, when alimentary canal and lungs (not gills) discharge permanently outside the egg the functions discharged transiently within the egg, first by the vitelline, and second by the allantoidal circulation.

How grows the mammal's egg? As grows the egg of a woman. The human embryo is, by the "after-birth" or placenta—which is formed in large part by transformation of the allantois, first into the chorion, then into the placenta—grafted upon the mother's womb, and derives its nutriment from the blood of the mother. But, it must always remain an inscrutable mystery to the special creationist, that the Omnipotent delays thus to graft the embryo upon the mother until about the fourth month, and insists on forcing the human and every mammalian egg to secure its nourishment: first, through the fishy and amphibious vitelline circulation, which, quickly disappearing, is replaced by the allantoidal circulation of the reptile and bird—which second circulation also quickly disappears to be replaced by, third, the placental circulation. Now, let it be observed, that, on the one hand, the vitelline circulation of the fish is bathed in water, thence obtaining air in abundance, and that the allantoidal circulation of the snake is in contact with the delicate porous egg-shell, through which air is readily absorbed; while, on the other hand, these two circulations in the human embryo are in contact, not with water nor with the external air, but with only one air-providing menstruum—the fluids secreted by the mother's womb—fluids which provide air, as also food, much less perfectly than is subsequently done by the blood of the placenta. Why then should the human embryo be furnished *temporarily* with the embryonic organs, first of a fish and amphibian, and then of a reptile and bird, prior to the development of the mammalian placenta—unless

these organs, less perfect and more transient than the placenta, be indelible marks of man's hereditary descent? The student of vital phenomena cannot ignore the important purport of "the appendages of the embryo" and of the elementary facts now stated—facts, which become of convincing significance when associated with those now to be presented.

The vitelline circulation is, by no means, the only indelible mark of man's piscine ancestry. Not until the sixth week does that *gill-apparatus* disappear, which, permanent in fishes, is transient in the embryos of reptiles, birds, and mammals. The human embryo has on each side of the neck, as has an adult fish, "branchial arteries" (five), distributed to cartilaginous "branchial arches" (four), which have between them "branchial fissures" opening into the pharynx. From the "branchial arteries" of most fishes are developed, for aquatic respiration, numerous vascular "gill-fringes" by which the air, dissolved in the water pouring through the "branchial fissures," is absorbed. But "gill-fringes" are useless to animals which do not breathe in water, and since disuse of these fringes should cause their atrophy in a human embryo, just as it *does* in a tadpole, it is in perfect accord with nature's laws that these gill-fringes are not present in the human embryo; even in some fishes they are dispensed with. In farther evidence that the embryonic branchial apparatus is perfectly homologous with the permanent gills of fishes it is found that, as the arterial system of the fish is formed from its branchial vessels, so the arterial system of the human embryo is formed from its branchial arteries—all of which gradually disappear by a conjoint process of atrophy, and of transformation into man's permanent arteries. Man's embryonic "branchial fissures," through which, in fishes, the air-supplying water passes off, also undergo transformation; however, as an anomaly, "original branchial fissures may persist in the neck, even in adults."*

Man's lungs are first developed as two little sacs, which, prior to the development of the trachea or windpipe, open temporarily, as the air-sacs of fishes permanently do, into the upper part of the alimentary canal—usually into the pharynx.

Man's embryonic heart is at first a simple tubular pulsating sac, like that of the lowest vertebrate—that exceptional and wonderful, heartless, and brainless fish, the lancelet or amphioxus. This single sac is soon divided by a septum into two sacs, and thus man has temporarily the two-chambered permanent heart of fishes. This piscine heart soon becomes a three-chambered reptilian heart, distributing, like it, impure venous mixed with pure arterial blood.† This snake-like heart does not become the perfect heart of the bird, mammal, and man, with its four completely separated cavities, until several days after birth; and, as an anomaly, the three-chambered heart may persist in man, causing the well-known "blue disease." As another peculiarity of the vascular system, man has but one great vein—the superior vena cava—to return the blood from the upper part of his body to the right auricle of the heart; but in his early embryonic condition, "two superior venæ cavae open independently into the auricle. This condition remains permanent in birds, and in some of the lower mammalia, which possess both a right and a left vena cava superior, opening separately into the right auricle. Instances are occasionally met with, from

* Page 953. Vol. IV., Cyclop. Anat. and Phys.

† The reptilian heart has only one ventricular, and two auricular cavities; while the human embryonic heart has only one auricular, but two ventricular cavities.

arrest of development, of two such veins in the human body."*

The "Wolffian bodies" are the permanent kidneys of the fish, and of his immediate descendant, the frog; but, they constitute only the "false" or "primordial kidneys" of higher animals. The human embryo possesses them until about the third month, when they disappear by atrophy, giving place to the permanent true kidneys. These are in man smooth and unlobulated, but are lobulated in lower animals—so they are in the human embryo, and, as a frequent anomaly, this lobulation may persist in the adult man.

Fishes, amphibians, reptiles, and birds, are *cloacal*, that is, have one common fecal and uro-genital outlet; so, the human embryo is cloacal to the twelfth week of its existence. The urachus, a relic of the allantois and of this cloaca, running from the bladder to the navel, is in some animals a pervious duct. "It has been found (says Wilson's Anatomy), pervious in the human fœtus, † and the urine has been known to thus pass through the umbilicus."

The "descent of the testicle" from the abdomen of the fœtus is by a pouch continuous with the peritoneal sac of the abdomen. This continuity, permanent in many lower animals, as in the rabbit, is habitually temporary in man; but may as an anomaly, persist, and thus cause the well-known "congenital inguinal hernia." Farther, this "descent of the testicle" is guided by a muscular cord, the gubernaculum testis, which at birth has lost its muscular character, and become (teaches Dalton's Physiology), "merely the anatomical vestige or analogue of a corresponding muscle in certain of the lower animals, where it has really an important function to perform" throughout adult existence.

The early embryonic womb appears bifid, and internally "presents a strongly marked triangular form, the vestige of its original division;" and, as anomalies, women may have not only "two-horned," but even "double wombs." Now, in apes, the womb is slightly notched, and, therefore, more distinctly bifid than in women; in cetacea, solipeds, and ruminants, it is distinctly "two-horned;" and marsupials, as well as some rodents have a "double-womb." ‡

The placenta is formed in part by the mother, and in part by her offspring—in women these two parts are eventually soldered inseparably together; but in the earlier stages of development these parts are separable, as is always the case in the cow and other animals. The fœtal part of the placenta is formed by numerous vascular tufts of the chorion—called cotyledons, which in woman are soldered together into the smooth, single "discoid placenta;" but in ruminants the cotyledons continue separate, and they have habitually a "cotyledonous placenta:" as an anomaly, a woman may have a cotyledonous, instead of the usual discoid placenta.§ The human fœtus is born linked to the placenta by the umbilical cord, which contains two umbilical arteries, and only one umbilical vein; but in the earlier stages of development there are two umbilical veins—which, always present in some lower animals, as (Topinard) in Cebian monkeys, may, as an anomaly, persist in the human fœtus.

Man's nervous system originates in a cord having one anterior bulbous enlargement, as is the permanent

form of the cerebro-spinal axis of the amphioxus. This single bulb, first separating into the "three cerebral vesicles," subsequently develops man's complicated brain. Thus, as in the successive classes of vertebrates, so in the successive phases of the human embryo's life are found developed all stages of the nervous system, from the simplicity of the amphioxus to the complexity of the highest mammal. Man's brain possesses no parts not present in the brains of the highest apes; * it differs from theirs, not in quality, but in quantity—in the greater complexity of the convolutions, in the lack of symmetry between the two sides, and in the greater size. But, our convolutions do not begin to be developed until the fifth month—even at the seventh month of fetal life, man's brain is as unconvoluted, and as symmetrical as is the adult baboon's; and, as anomalies, human beings may be born as destitute of brain as is the amphioxus—and the brains of congenital adult idiots, seldom weighing more than twenty-three, may not exceed even eight and one-half ounces—while the average weight of the gorilla's brain is about seventeen ounces.

Man's bony system passes through a cartilaginous stage, which, temporary in him, is permanent in some fishes; and our bones present other indelible marks of our lowly origin, besides those which follow.

The single adult frontal bone (forehead) consists in lower animals of two separate pieces; such is its condition in the human embryo, and these two frontal bones are not united until the first year after birth,—as an anomaly, this union may never take place.

In some apes and other mammals the malar, or cheek-bone, is permanently divided in two portions; and this sometimes occurs in the human embryo.

Lower animals have a distinct inter-maxillary bone for the incisor-teeth of the upper jaw; so to the fourth month has the human embryo. The final union of the inter-maxillary with the superior maxillary bones is marked by a fissure for some three years after birth, and, by arrest of development, may never take place—thus causing, as an anomaly, the well known deformity—hare-lip.

In the human embryo, "at one time, the two nasal passages or fosse are closed at the bottom, a condition which is permanent in fishes; afterwards they communicate, in front of the palate, with the mouth, as in certain amphibia; finally, they open only into the pharynx, as in reptiles, birds, and mammals." †

In the human embryo the great toe is shorter than the others, and farther from them,—even projecting at a right angle,—as is its permanent condition in the quadrumana.

To the eighth week the coccygeal or tail-bones of the embryo-man project beyond the rudimentary legs, and as far beyond as in the embryo-dog. This veritable tail, though usually aborted, may, as an anomaly, persist, as shown by Mr. Owen, who, April 25th, 1878, related to the Harveian Society of London "a case of a fetus he saw, which had a tail that was curled up on one buttock and distinctly moved. It was successfully removed by ligature, and was now in the museum of Guy's Hospital. The child lived to sixteen years of age." ‡ That the coccyx is an indelible mark of a true ancestral tail, is further indicated by the presence, even in the adult, of muscles which for-

merly moved it, but which, by long disuse, have atrophied and become rudimentary.*

Finally, the poetical seven stages of man's life outside the womb are even surpassed by those within it, as numbered by embryologists. The most striking of these embryonic stages are, the Ascidian, the Amphioxian, the Piscine, the Reptilian, the Mammalian, the Quadrumanous, and the Human. What theory, other than evolution, offers even an attempt to rationally explain the significance of these stages, and of the facts now presented?

ANOMALIES.

Anomalies are deviations from the habitual construction of the body; the grossest are termed monstrosities, others constitute deformities, while the greatest number are simple deviations without being, in any wise, malformations. Most anomalies represent anatomical structures habitually found in lower forms of life, hence constitute what evolutionists term—*reversions*. Examples of monstrous, then of ordinary anomalies, will now be given.

A monster † is not, as until recent times was taught, an instance of "divine vengeance," nor a "work of the devil," nor a result of bestial intercourse, nor a *lusus naturæ*, nor the product of a creative force of special kind; but is due sometimes to excessive, sometimes to perverted, or, far more frequently, to defective embryonic development. Since the transient forms of the human embryo are, for the most part, repetitions of the persistent forms of lower animals, it is not singular that malformations due to arrested development should present a brute-appearance; nor is it singular that our ancestors, ignorant of embryology, should long have erroneously ascribed beast-like monsters to bestial intercourse, and that this error should still find credence among the ignorant.

The human embryo is, in its earliest stages, as destitute of head, brain, heart, and extremities, as are the permanent forms of many lower animals; hence, from arrest of development, a human monster may be born as headless as a worm, as brainless, and heartless as the amphioxus, and as limbless as a snake. Every variety and degree of deficiency in these and other parts, from complete absence to perfect development, may occur. Not only may development be arrested prior to the separation of the head from the trunk, thus producing a headless monster, but there may be a partial arrest producing a brutish, frog-like deficiency of neck; not only may the four extremities be all wanting, as in the worm and snake, but the hands or feet may, turtle-like, be attached to the shoulders or pelvis, and the two lower extremities may coalesce into one, as in fishes. Man's embryonic eyes are at first located on as diametrically opposite sides of the head as are the eyes of fishes, or of rodents; hence, by defect of development, may result human monsters, thus hideously deformed.

Before citing other examples of anomalies it is well to recall, that in addition to the above monstrosities, some fourteen instances of ordinary anomalies have already been presented in connection with embryology. To this list of reversions may be added the following indelible marks of man's lowly origin:

* Gray's Human Anatomy, Am. Ed., p. 228, says, "the extensor coccygis is a slender muscular fasciculus, occasionally present, . . . it is a rudiment of the extensor muscle of the caudal vertebra present in some animals."

† Human monsters are reported by some to occur as often as once in every 1,600, and by others once in every 3,000 deliveries. Fortunately many die early.

The vast majority of flowering plants, and also many inferior animals (as tape-worms, slugs, snails, etc.), are "double-sexed," and it is now generally conceded that *true* hermaphroditism is, in man, "not only possible, but probable."

Many lower animals have a "penial bone," and as a relic of this "a prismatic cartilaginous body has been occasionally found in the centre of the glans" penis of man.*

Instead of having one nipple to each breast, or mamma, a woman may have, like some lower mammals, additional supplementary nipples; and her mammae may, like the Monotreme's, be destitute of nipples. A woman may have, instead of the usual two pectoral mammae, supplementary mammae sufficient to furnish her with five breasts; she may have on the belly, the abdominal mammae of Marsupials, or in the groin, the inguinal mammae of Ruminants. She may have, like the Lemur, the lowest animal of man's order, the primates, two pectoral, and two inguinal mammae. Among all mammals a marked relation exists between the number of mammae and of young at one birth; and it is found that a woman may have occasionally, as some lower animals have habitually, two and even five living young at a birth.†

Man has occasionally a supplementary spleen, which is constant in the sturgeon, dolphin, narwhal, and doubtless in other animals.‡

Many birds have a "vitelline cecum," that is, a pouch-like process, or a "short, narrow, blind diverticulum, connected with the small intestine;" "a similar diverticulum is occasionally found in mammalia, and even in man."§ Man may be web-fingered and as web-toed as a duck, and he may have two toes occasionally webbed, as they constantly are in the gibbon.

In man there is occasionally a simian conformation of the cartilage of the ear ("square above, rounded off, and without a lobule"); he may be born as destitute of external ear as a fish, frog, or snake, and as eyeless as a fish from the Mammoth Cave.

Like Esau, and many more recent instances, man may be as hairy as are most of his mammalian ancestors; and, he may have, instead of ordinary nails, as solid claws on fingers and toes as have the Carnivora.

Anomalies of the bones are numerous. There may be complete fusion of the two parietal bones into one, as in rodents; and there may be, as in some lower animals, an interparietal bone. In the white race the two bones proper of the nose remain separate to an advanced age, as is not the case in other animals; but their fusion may occur early, especially in the inferior races of man, as for instance in Hottentots about the twentieth year; while in the chimpanzee and gorilla it occurs about the second year.¶ The spinous processes of man's 3d, 4th, 5th, and 6th cervical vertebrae are habitually bifid, but they are, especially in the inferior races, sometimes simple, as they constantly are in lower animals; however, the chimpanzee has two of these processes bifid, thus pre-

* Huxley's Vertebrates, p. 417.

† Churchill reports that in 448,988 deliveries, twins occurred once in 78, and triplets once in every 5,831 cases.

‡ To correct frequent misapprehensions of two sexual questions, it may be here added, that Flint's Physiology, p. 875, teaches that monkeys, as well as women, have a monthly cutaneous discharge; and Topinard's Anthropology, p. 150, teaches that the gorilla and chimpanzee are monogamous.

§ Mivart's Element. Anat., p. 484.

¶ Macphall's Physiology, Eng. Ed., p. 187, v. 2; and p. 622, Wilson's Anatomy.

‡ In 1864 one such case was seen by the writer, at Macon, Ga., in a Confederate conscript, who stated that his long, round, solid claws were inherited, and had been transmitted to one of his children.

§ Topinard's Anthropology, p. 127.

senting in this particular a *transition* form. Man has occasionally—instead of his habitual twelve dorsal and five lumbar vertebrae—the thirteen dorsal and four lumbar vertebrae of the gorilla and chimpanzee; or the twelve dorsal and four lumbar vertebrae of the orang. Instead of twelve, man may have the thirteenth rib, out of which Eve was conjecturally made, and which some lower animals habitually possess.

Many animals have—to protect the principal artery and nerve of the humerus from compression—a “supra condyloid foramen,” which is occasionally found in man, it is said, once in every hundred cases; still more frequently is found a small hook-shaped process, as a rudiment of this foramen.*

In some fishes and crocodiles, says Mivart, several successive series of new teeth appear to replace old ones; so, occasionally in man, there may occur a third, and perhaps even a greater number of series of new teeth.

Occasionally in the superior, frequently in the inferior races, man's lowly origin is stamped upon him by the projecting upper incisors of the anthropoid, by his prognathous under-jaw, and by his monkey-like “facial angle.”

A man has more than five hundred separate muscles; variations in number and attachment are frequent, particularly in negroes; and these variations or anomalies constantly illustrate reversions to lower animals, and especially to the anthropoids. Topinard asserts that the sternal muscle of mammals is present in 18 of 600 men; that the ischio-pubic muscle, constant in the majority of male animals, is present in 19 of 40 men; that the levator claviculae of most apes is present in 1 of every 60 men; that in one man, seven muscular peculiarities of certain apes have been found; and that a marked muscular peculiarity of anthropoids and monkeys, as distinguished from men, is the habitual presence in the former and absence in the latter of an accessory fasciculus of the latissimus dorsi, but that this fasciculus has been “observed in a rudimentary state in some negroes.”†

Huxley teaches,‡ that man has usually only two muscles,§ which the anthropoids do not have, but that the one is sometimes, and the other is frequently wanting in man; that the anthropoids have usually only four muscles,|| which man does not have, but that all these are sometimes absent in anthropoids, and present in man; and, in fine, that “all the apparently distinctive peculiarities of the myology of the anthropomorpha are to be met with occasionally, as varieties in man.”

RUDIMENTARY ORGANS.

Rudimentary organs found in all kinds of plants and animals, are the perfectly useless, and at times, even detrimental relics of useful organs in lower forms of allied plants and animals. The presence of such relics in the adult, and their better development in the embryo, are among the most convincing evidences of evolution; while to him who believes that all things were specially created for some special and useful purpose, these relics must continue to always be “inscrutable mysteries.” How is it possible to

explain, except by the *derivative* creation of evolution, such facts as follow?

The canine and upper incisor-teeth of ruminants exist in a rudimentary state, but are invisible, because they never rise above the gum; so also, the fetal whale has teeth which are never cut. Many insects have wings; lying under wing-cases which are firmly soldered together. Even entire limbs may be rudimentary—certain snakes having hind-legs hidden beneath the integument.* There often reappear the stump of a tail in tailless breeds, minute dangling horns in hornless breeds of cattle, the vestige of an ear in earless breeds, and the rudiments of eyes in eyeless animals.

The rudimentary organs of man, if neither so surprising nor so numerous as in lower animals, are as significant. To the several examples heretofore presented will be added the following:

The porpoise, the hedgehog, horse, and other brutes, have a highly developed group of skin-muscles, termed the panniculus carnosus—which is rudimentary in man, being represented only in part; for instance, by the platysma myoides in the neck, by the occipito-frontalis over the skull, and by occasional traces in the arm-pits, and other localities. The fibres of the rectus muscle of the abdomen are interrupted at intervals by from two to five transverse tendinous intersections—termed lineæ transversæ, which are the vestiges of ribs in some mammals, and especially in reptiles.† Although few men can move the external ear, and even these imperfectly, yet all men have three rudimentary ear-muscles,‡ which are the analogues of large and important muscles in some of the mammalia. A small projection, sometimes found on the superior border of the helix of man's ear, is believed by Darwin to be the vestige of an ancestral pointed ear.

Man, and all male quadrupeds have rudimentary mammae, which, considered in connection with “double-sexed” anomalies, have, no doubt, a deep significance. Man has, over the whole body, rudimentary hairs, which are supposed to be vestiges of a uniformly hairy coat. Man has a small laryngeal sac, the ventricle of the larynx, which is believed to be the rudiment of a very large cavity in anthropoids, and in other animals. The white man's third molars, or wisdom teeth, are sometimes never cut, are especially prone to decay, have only one root instead of two or three, and are smaller than the first and second molars; since this is not the case in lower animals, nor in apes, nor in the inferior races of man, it is believed that the European's wisdom-teeth are *tending to become* rudimentary.

In mammals generally, and in lower vertebrates, there is present in each eye a “nictitating membrane,” or “third eyelid,” which often, if not always, springs from the inner and nasal side of the eyeball; in the same part of man's eyes is constantly found, as a rudiment of this third eyelid, the semilunar fold, or “plica semilunaris.”§

One of the best known, and most remarkable of the rudimentary organs of man, is that worm-like ap-

* Gray's Anatomy, Am. Ed., p. 131, teaches, that this foramen, or its rudimentary hook-like process, are, when present, found “some two inches above the internal condyle.”

† Topinard's Anthropology, p. 93. However, Gray's Anat., Am. Ed., p. 272, teaches that an accessory of the latissimus dorsi is found in one of every 15 men.

‡ Huxley's Vertebrates, pp. 408, 417.

§ The extensor primæ interossei pollicis, and the peronei tertii.

|| The levator claviculae, dorso-epitrochlearis, scan-onibus and abductor ossis metacarpi quinti digiti.

* Dalton's Physiology, p. 614, teaches that the anterior extremities of the embryo-frog are at first concealed beneath the integument.

† Mivart's Element. Anat., p. 239, says, “The lineæ transversæ may be absent, as in the hedgehog, etc.; or they may be seven in number, as in the racoon, or they may be replaced by regular abdominal ribs, which subdivide the rectus into a longitudinal series of successive segments, as in the chameleon.”

‡ The atloides, atlocheus, and retrahens auris.

§ In dogs, cats, and carnivora generally, the eyelids do not separate from each other until eight or ten days after birth, and in the human foetus they remain adherent to the sclerotic membrane.

pendage to the cæcum, or head of the large intestine, called the appendix vermiformis cæci. The highest apes, and, it is said, the marsupial wombat, are the only animals which share with man the honor of possessing this curious and useless organ—which serves no purpose, thus far conceived by human ingenuity, except either to occasionally cause death, as by impact of a cherry-stone, or to present a very indelible mark of man's lowly origin. To properly estimate this cæcal appendage, a few facts in comparative anatomy must be understood.

The cæcum is a pouch-like elongation of the large intestine at its junction with the small intestine. The ant-eater and armadillo have, as birds generally have, two such blind elongations, or a "double cæcum;" the manatee has a bifurcated cæcum; but mammals, as a rule,* have only one cæcum, which always large, may be of enormous size, as in the hare, the indris, the marsupial koala, the horse, and in ruminants. The cæcum of the koala is three times the length of its body, while that of the horse is longer than three feet, and holds more than seven gallons. Farther, lemurs have a peculiar cæcum, in that, it is "drawn out into an elongated conical termination;" and some, if not all, carnivora, have a "spirally twisted" cæcum. †

These facts seem to throw light on the gradual transformation of the large mammalian cæcum into man's insignificant organ, ‡ which has attached thereto a small, elongated, worm-like, conical, and spirally twisted appendix. Can any doubt remain that this appendix is the vestige of the long and large cæcum possessed by man's mammalian ancestors? If so, the doubter is required to explain why it is that in his own, as in every man's early embryonic development—his cæcal appendage was, at first, long, of large size, and as wide as the cæcum itself, so wide that the small intestine seemed to be inserted into the side of the large intestine, leaving a large pouch-like free end, which, becoming by degrees conical, was gradually constricted and twisted into the adult's familiar, small, and worm-like appendix? Such doubters have no refuge from the scylla of "*derivative creation*," except in the charybdis of "*inscrutable mystery*."

Comparative anatomy has already acquired sufficient knowledge to increase the long list, now given, of the indelible marks of man's lowly origin. As the future perfects this knowledge, not only will there be many important additions, but a brighter light will be thrown on the facts herein presented. However instructive such detailed facts may be, yet, only a fraction of the evidence in favor of evolution depends on human anatomy; and the general facts are as decisive as are details to him thoroughly imbued with a conviction of the simplicity, uniformity, and constancy of nature's laws. For chemistry teaches that man's chemical, microscopy that his histological, morphology that his homological structure, agrees with the whole animal kingdom. Paleontology has stamped in permanent letters of stone the same succession of animal life, impressed by fleeting hours on the offspring within the womb of every mother; and

comparative anatomy, physiology, and pathology, present innumerable general, as well as special facts, to prove—that man, though ultimately formed of those chemical elements, which constitute in part, "the dust of the ground," was not formed directly out of these lowly dead inorganics, but had his immediate origin from the very highest organic living matter.

A CASE OF PUERPERAL ALBUMINURIA. WITH URÆMIC SYMPTOMS, TREATED BY JABORANDI.

BY ELIZABETH M. CUSHIER, M.D.,

RESIDENT PHYSICIAN OF NEW YORK INFIRMARY.

At the last annual meeting of the Gynecological Society, Dr. T. G. Thomas suggested the use of jaborandi in the treatment of the parenchymatous nephritis of pregnancy. Upon reading this suggestion in the minutes of the Society, published in THE RECORD at the time,* I thought that the report of such a case, which had already occurred under my own observation, and where jaborandi had been successfully employed, would not be devoid of interest. It is believed that some of the details of this case may moreover help to throw light upon the exact modus operandi of this medicine in the treatment of uræmic symptoms.

Agnes H., prim., entered N. Y. Infirmary for Women and Children, for confinement, on September 5, 1878. The patient gave a history of having been in poor health during her entire pregnancy, but no satisfactory details regarding it were obtained.

Upon seeing the patient I was struck by the pallor and slight puffiness of the face. Elsewhere there was no œdema, excepting to a very slight degree in the lower extremities. An examination of the urine giving perfectly normal results, it was concluded that the œdema was due to anemia alone, and treatment was directed to this.

From this time the general condition improved; her face assumed a better color, and she reported herself as quite well until the evening of Sept. 28th, when she complained of having had headache and nausea during the afternoon. Her face was flushed and the tongue coated. The temperature and pulse were normal. A cathartic was given, and the urine directed to be again examined.

On the following morning the patient was reported as having been very restless during the night. The bowels had not moved, nor had any urine been passed since 5 P.M. of the day previous. The face was now decidedly œdematous. The headache and nausea were very much increased, and there was marked impairment of vision. Four ounces of urine were removed by the catheter, and upon examination it was found to be loaded with albumen. At 9 A.M. a purgative was administered, but it was immediately vomited. An enema was then given containing three minims of croton-oil, and was followed by two small stools. The hot-air bath was then employed with the effect of producing only a slight moisture of the surface. Later, considerable pain in the region of the kidneys being complained of, dry cups were applied, with relief. The nausea persisted with occasional vomiting, and the patient was unable to retain even a little milk or water. Microscopic examination of the urine at this time showed blood-corpuscles and small waxy casts.

At 4 P.M. one-sixteenth grain of pilocarpine was

* Human anatomists habitually assert or imply that all mammals have a cæcum; but, Mivart's Element. Anat., pp. 447-8, teaches that "the presence of a cæcum is not quite constant in man's class," for "it may be wanting altogether, as in the hedgehog, weasel, porpoise, and others."

† The cat, dog, and other carnivora, says Chauveau's "Comp. Anat. of Domesticated Animals," p. 417.

‡ Man's cæcum is a small reservoir, only 2½ inches in length; his cæcal appendage is very variable in length, usually about three, it may be six inches long. This variability is significant.

given hypodermically, and repeated three times at intervals of half an hour. A decided moisture of the skin followed, but no profuse sweating.

At 5 p.m. five ounces of urine were removed, which upon boiling was found to be two-thirds loaded with albumen.

At 7.30 p.m. another effort was made to move the bowels, a half-grain of elaterium being given per rectum. This was repeated at 11.15 and at 11.30 p.m. without effect.

On the following morning the patient was reported as having slept somewhat during the night. She had vomited but twice, and had retained a little milk. The headache and nausea were diminished; the bowels had not moved, however, nor had any urine been passed. The pulse was at this time 84, and the tension very much increased. At 11 a.m. seven ounces of urine were drawn. The character was the same as before. At about this time Dr. Putnam-Jacobi saw the patient, and advised the administration of pilocarpine in larger doses. A half-grain was accordingly given hypodermically, and was followed within five minutes by profuse sweating, ptyalism, and vomiting of mucus. During the afternoon there was very marked improvement in the symptoms. The headache and nausea subsided, and milk was retained without difficulty.

At 7 p.m., as there had still been no movement from the bowels, the patient received one-quarter grain of elaterium by the mouth. This was repeated at 9 and 11 p.m. At 4 a.m., Oct. 1st, there was a small stool.

During the morning seven ounces of urine were drawn. There was no diminution in the amount of albumen. Blood and casts were still present—the former, however, in less quantity. At this time a decoction of scoparius was ordered, half an ounce to be given every two hours during the day. At 7 p.m., as the amount of urine passed was still very small, the jaborandi was repeated—this time in the form of the fluid extract, of which ʒj. was given. The sweating

The labor progressed, and terminated naturally at 1.30 a.m., Oct. 6th. During the latter part of the labor there were at times marked dilatation of the pupils and extreme pallor of the face. No serious symptoms, however, manifested themselves. Immediately after labor the patient complained of severe pain in the head. The pain was referred to the vertex, and was apparently most intense. It was controlled by morphine.

At 11 a.m., on the 6th, six ounces of urine were drawn; this being all that had been excreted since the previous day, unless it had been involuntarily passed during labor. It was found to be nearly solid with albumen. The decoction of scoparius was again given, and during the night the urine began to be more free. The pulse, which had varied from 72-84, and which had been increased in tension, now became more rapid, varying from 96-108, and the tension was very much diminished. The urine continued to be passed freely—reaching, on some days, as high as 40-42 ounces. The albumen diminished in amount, and the blood-corpuscles disappeared. There were still present, however, very slender hyaline casts. On Oct. 29th, the patient was discharged in an apparently very good condition, although the albumen had never entirely disappeared from the urine.

It seems quite probable, judging from the severity of the symptoms at the beginning of the evidence of uræmic poisoning, that serious trouble might have arisen at the time of labor, had not very active treatment been resorted to; and of this treatment it is evident that the jaborandi was followed by the most decided results. Diuretics were without effect until the renal congestion had been relieved, and the cathartics employed for this purpose were quite ineffectual, although care was taken to procure a good preparation of the elaterium. It is noticeable that although the uræmic symptoms had disappeared, it was not until after profuse diaphoresis had taken place a second time that the kidneys began to act.

FIG. 1.

FIG. 2.

was again profuse, and during the night the urine began to flow freely. From this time there was neither headache nor nausea. The puffiness of the face diminished, and food was retained and relished. The urine continued to flow freely; it was still, however, loaded with albumen.

Oct. 5th, 7.30 p.m.—Patient began to have slight labor-pains, and with the object of warding off any possible danger from an increase of the renal congestion during the effort of parturition, the jaborandi was repeated, with the same effect as before.

notwithstanding diuretics had been previously employed.

The jaborandi was not followed by any undesirable effect either upon pregnancy or labor. The latter—although the pregnancy was fully at term—did not take place until a week after the beginning of the administration of the drug.

The following analysis of sphygmographic traces, taken at different periods of the attack, has been given to me by Dr. Putnam Jacobi.

The first traces were taken September 30th, the day

after the first appearance of the uræmic symptoms. Pilocarpine had been given the day previous, but with only slight effect in producing perspiration. Typical trace-pressure of 8 oz., Fig. 1; percussion stroke vigorous, but oblique and short; systolic apex extremely rounded, passing into developed tidal wave; scarcely any trace of diastole; no elasticity oscillations; ventricular systole prolonged. The traces were almost as much developed under high pressure as under lower. All these characters show high tension of vascular system dependent upon repletion of some portion of it, which repletion offers considerable resistance to the cardiac impulse. After profuse sweating from one-half grain of pilocarpine, trace changes. Under

of an excess of water from the blood.* It is evident, moreover, that an abnormally high tension of the vascular system, together with intense albuminuria, is not sufficient to cause the cerebral symptoms. As in this case both these conditions persisted, while the latter symptoms were absent, two hypotheses suggest themselves to explain the action of the jaborandi:

1st. The excessive secretion of the perspiratory glands sufficed to remove from the blood not only an excess of water, but also the poisonous organic substances usually excreted by the kidneys (urea, extractive.)

2d. The determination of blood to the skin to meet this exaggerated activity of the sweat-glands

FIG. 3.

pressure of 9 oz. Fig. 2, the tidal wave is less developed, and, from the aortic notch to the end of the curve, the line is flattened instead of rounded, as in the first traces. This shows that the wave of blood reflected from the aortic valves on their closure is smaller in the second case than in the first. In other words, the tension has been positively, though not very markedly, diminished by diminution in the contents of the arterial system. The force of the heart remains unaltered. The diminution in intra-arterial pressure can only have been effected indirectly by diminution in the venous tension through the profuse diaphoresis. The uræmic symptoms, once dissipated, did not return, but the urine continued to be loaded with albumen. The third series of traces were taken on October 4th. At this time the high arterial tension was found to have been reproduced, but entirely unaccompanied by uræmic symptoms. The urine, although more abundant, was still loaded with albumen. The patient felt perfectly well. In this series of traces the curve was developed at a very low pressure (three ounces), Fig. 3, which with Mahomed's sphygmograph usually gives no tracings at all. The artery, however, continued to yield abnormally developed curves under a pressure of ten ounces, and even under eleven, at which it is usually extinguished; the curves were more full than is often found in women. Diastole was effaced. From all these characters we must infer that, under the influence of the tubular nephritis obstructing the transudation of water, the serous repletion of the vascular system had been reproduced, while the complete absence of uræmic symptoms would show (at least in accordance with a theory partly based upon this very class of cases) that the cortex of the kidney was at this time unaffected.* The transitory uræmia would then be explained by a temporary congestion of the cortex complicating the ordinary medullary or superficial nephritis of pregnancy.

Since the relief afforded to the uræmic symptoms by the pilocarpine was out of proportion to the alteration in tension of the radial pulse, it is evident that the diaphoresis must have acted in some other way than by lowering the general vascular tension, by the removal

acted as a derivative to the circulation of the kidneys, and thus relieved the congestion of their cortex. The desquamative lesion of the medulla remained untouched, and therefore the albuminuria persisted. Further, in a general afflux of blood to the periphery the peripheric radial artery must necessarily share, and by this must its tension be increased, even though the tension of the central vascular system had been lowered. This circumstance may explain the fact that the radial pulse was so little altered after the administration of the jaborandi. Had sphygmographic tracings been taken of the carotid or of the heart, a greater difference might, perhaps, have been demonstrated.

ABSCESS OF THE LIVER FOLLOWING DYSENTERY.—ASPIRATION.

DISCHARGE OF PUS INTO THE PERITONEAL CAVITY.
—DEATH.

By WM. PEPPER, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN THE MEDICAL DEPARTMENT
OF THE UNIVERSITY OF PENNSYLVANIA.

A. McC., æt. 39, employed in Philadelphia Gas-Works. Has always, until lately, enjoyed general good health, and has always been a sober, steady man. In August, 1878, he was attacked with dysentery, which lasted for three weeks, after which he apparently convalesced. In a few days, however, he was attacked with irregular rigors about noon, followed by fever during the afternoon and evening, and marked sweating at night. This state of affairs continued about one week, when he began to improve; the fever diminished, or ceased, and, although weak, he returned to work. One week later the same symptoms recurred, and he was again confined to the house for a week. He then again improved, and was able to do a little work for four days; after which he was for the third time attacked with an irregular fever of a hectic type.

During most of the above time there had been increasing pain in the region of the liver. In the early

* Lecorché adduces such cases as proof, among others, that the separation of the water of the urine takes place in the medullary tubes, and the separation of the urea and salts in the glomeruli and convoluted tubes of the cortex.

* Eine Hypothese über den Zusammenhang in welchem die sogenannten uræmischen Anfälle zur Erkrankung der Nieren stehen. Traube, Gesammelte Abhandlungen. Bd. II., p. 551.

part of November this pain became very severe. It was then chiefly referred to the region of the gall-bladder and the lower part of the liver. Occasionally it extended through to the back, or up towards the right shoulder. A dry cough, attended with some pain, appeared in November. He had marked night-sweats, and lost flesh, strength, and all appetite. He was then treated for typho-malarial and gastric fever.

I saw him first on December 1, 1878, at the clinic of the University Hospital, and found a distinctly increased area of liver dulness, with some fulness of the right chest over the site of the liver. There was also marked tenderness over the gall-bladder and up to the sixth interspace in the line of the right nipple. There was distinct yellowness of the skin, almost amounting to jaundice. The urine was dark, and the stools light yellow. I was satisfied that an abscess of the liver existed, but as the patient was obliged to return home, aspiration could not be performed. Poultices were kept constantly applied, and atropia and morphia were given to check the night-sweats and to induce sleep. There was always an increase of the pain felt upon motion. During the next few days the constitutional disturbance increased markedly.

On December 8th I saw the patient again. The yellow tinge of the skin was then very apparent. The pulse was small and excitable—112 to the minute; the respirations were 27. There was marked impairment of motion over the lower part of the right chest. A careful inspection showed some fulness of the hepatic region, as compared with the left hypochondriac region. The fifth, sixth, seventh, and eighth intercostal spaces on the right side were filled out level.

By percussion, the following results were obtained: the right lobe of the liver was found to extend below the margin of the ribs. In the region of the gall-bladder, especially, there was well-defined resistance over an area of two square inches. The dulness in the line of the right nipple extended upward to the fourth rib. Laterally, it either reached the same level, or extended somewhat above it, towards the posterior border of the axilla. In the sitting posture, the upper line of dulness in front varied very slightly, the line of absolute flatness rising not more than one-half of an inch. The dulness in the axilla fell slightly. Posteriorly, dulness extended up to the angle of the scapula, and complete flatness up to within one inch of that point. When the patient turned on the left side, there was a decided falling in the line of dulness laterally and anteriorly, and posteriorly round to the very vertebral gutter. Percussion showed, however, that in this position there was no depression of the liver below the margin of the ribs. It was thus clear that there was very little, if any, pleural effusion of a liquid character, but that the changes in the level of dulness were chiefly due to the varying degrees of expansion of the right lung. Over the area of flatness there was absence of respiratory murmur and of vocal resonance; but vocal fremitus was obscurely felt downward as far as the upper part of the hepatic area. Posteriorly, there was feeble respiratory murmur, with crackling sounds (dependent upon the plastic pleural exudation), for an inch and a half below the angle of the scapula.

There were no signs of disease in the upper part of the right chest or of the left lung. The heart was displaced upward and toward the left, the apex-beat being in about the position of the left nipple.

Excessive pain was felt in moving or turning. There was tenderness over the region of the gall-

bladder, and to some extent over the anterior surface of the liver; but careful palpation showed that the tenderness was by far the most intense over a circumscribed spot in the line of the right nipple and in the sixth interspace.

The smallest-sized aspirating needle was introduced to the distance of one and one-half inches at this point, in a direction slightly upward, and f. 3 iv. of dark, thick, grumous pus were withdrawn. Some immediate relief was experienced. When the needle was first introduced, it was free to move in the cavity; but, after the pus had ceased to flow, the roughened wall of the abscess could be distinctly felt by the point of the needle.

No larger canula was introduced, because it was thought to be safer to watch the effect of the partial aspiration; and, in case the same symptoms recurred, to repeat it later. Very little, if any, change was produced in the physical signs by the withdrawal of the above small amount of pus, and it was therefore evident that the main collection remained.

The patient slept much better during the following night, and was easier on the next day. On the second day, when I next saw him, he expressed himself as feeling very greatly relieved. There had been some slight return of appetite, and he had slept much better. There was also some reduction in the rapidity of the pulse. The physical signs remained the same, and there was still marked soreness upon pressure at a point in the sixth interspace, somewhat to the left of the point of juncture.

The same evening (Tuesday, December 10th), about eight o'clock, he was seized with a sudden and very violent pain, extending through from the hypochondrium to the back, near the angle of the right scapula. His breathing was oppressed, and he had nausea. On Wednesday morning he was evidently sinking from the shock of the sudden peritoneal inflammation. The pulse was rapid and thready; the breathing hurried and gasping. The belly was distended and tender. Extreme pain was felt over the hepatic region. There was great thirst. The stomach was unretentive. These symptoms persisted, and on Thursday night he died.

At the *autopsy* the head was not examined. Upon opening the abdomen the peritoneum was found to be congested, and there was a considerable quantity of grumous pus, similar to that which had been removed by aspiration, diffused throughout the abdominal cavity. There were not, however, any marked deposits of recent lymph. The omentum was drawn upward, and was found to have attachments, by soft, yellowish lymph, along the line of the lower margin of the ribs. When it was released, the anterior border of the liver was found to project two and one-half inches below the ribs at the position of the gall-bladder. The left lobe of the liver was but slightly enlarged. There was marked perihepatitis with flakes and layers of soft yellow lymph. There was also a considerable quantity of the same dark, grumous pus confined between the diaphragm and the liver. Upon removing the liver, its upper surface showed extreme bulging, due to the presence of an enormous abscess in the right lobe. The wall of this abscess was thin, and it fluctuated upon the slightest touch. It was of a pale grayish-red color, and in one circumscribed point presented a blackish, gangrenous appearance; it was found that perforation had occurred here. The point at which the aspirating needle had been introduced was not visible, but, by compressing the abscess, a few drops of pus could be forced out of a minute aperture which was presumably the point of puncture.

On opening the abscess it was found to be not less than six inches in diameter, and was filled with thick, shreddy pus of varied colors. The wall limiting the abscess was, with the exception of the upper portion, firm and whitish. No minute examination of it could be made. The rest of the liver was softened and pale.

The diaphragm, corresponding to the superficial part of the abscess, was much softened, and tore very easily. Its peritoneal surface was covered with soft, yellowish lymph. There was no appearance of a near approach to perforation of the diaphragm.

Doubtless the tendency was to perforation of the diaphragm, and to the discharge of the abscess into the lung, but the adhesions between the liver and diaphragm were too soft, so that the peritoneum ruptured and the pus discharged between them.

The right lung was closely adherent throughout; the adhesions being comparatively recent, especially over the lower lobe and over the diaphragmatic surface.

The left lung was not adherent save at a few points. Throughout both lungs, which were highly pigmented, were numerous shot-like bodies. Upon section, these were proved to be dry, whitish, caseous, encapsulated collections. Whether these were connected with the abscess, or simply due to his occupation in the gas-works, was hard to determine, though the latter is the more probable supposition.

The heart was healthy, but was pushed to the left and upward; its apex being situated under the site of the left nipple.

Remarks.—It is unfortunate that the circumstances under which the patient was first seen made it impossible to aspirate the abscess promptly. During the ensuing week such destructive changes occurred as to render a favorable result impossible. The abscess had already ruptured and a portion of its contents had escaped into the space between the liver and the diaphragm. The adhesions which had formed were too soft to long retain it here, and aspiration secured only a brief period of relief.

The abscess was in this case clearly connected with the preceding dysentery, and was probably embolic in its original character. The irregular and intermittent course of the hectic symptoms in the earlier part of the case is interesting, and perhaps points to different foci of suppuration which coalesced later. The position of the abscess would have made it a favorable case for treatment if its nature had been recognized earlier.

In reference to the recent discussion concerning the frequency of hepatic abscess, I may state that this lesion is undoubtedly somewhat rare.

HYPODERMICS OF ETHER IN SCIATICA.—Dr. C. G. Conneys claims (*Cincinnati Lancet and Clinic*) that hypodermic injections of ℥. xxx. of sulphuric ether (one night and morning, passing the needle a little posterior to the great trochanter) have cured this obstinate affection in his and in others' hands.

CHLORATE OF POTASSA POISONING.—Half an ounce swallowed by a two and a half year old child, through mistake, gave rise to severe gastritis and acute vomiting, which resulted in death in spite of treatment.—*Algem. Med. Central-Zeitung*, 1878, No. 89.

SULPHUROUS ACID IN PRURITUS VULVÆ is highly recommended by Dr. E. B. Stevens. Applied in its full strength it gives prompt relief.

Reports of Hospitals.

GUÉRIN'S COTTON WOOL DRESSING IN THE PARIS HOSPITALS.

By M. J. HALLORAN,

Élève at La Pitié Hospital.

SERVICE OF M. VERNEUIL.

PARIS, FRANCE, Jan., 1879.

IN this note, suggested by a recent clinical lesson at La Pitié, by M. Verneuil, we do not by any means intend to consider this apparatus in all the numerous applications to which M. J. Guérin has put it, but merely to recall the cases, or at least some of them, in which we have seen it used during the two years and a half that we have been élève in the Paris hospitals.

As is well known, M. J. Guérin insists on perfect occlusion with compression; to obtain this he applies, first, two or three layers of cotton-wool, then a linen band tightly drawn over all, then another layer of cotton, then another band, and so on, until, in a case in which he applied it at St. Bartholomew's Hospital, at London, he used up five pounds of cotton-wool; we confess we have never seen him carry the idea so far in his own service.

The first case in which we saw it applied was in M. J. Guérin's service—a case of bad, complicated fracture of the leg—the patient, a woman, having been run over by an omnibus. The result was excellent; the fever was very moderate, the patient suffered very little, and left the hospital with the fracture consolidated and the wounds healed.

We next saw the apparatus employed several times in the service of M. Gosselin; but it could hardly be called the dressing of M. J. Guérin, for M. Gosselin, like M. Verneuil, being opposed to the doctrine of union by first intention, and fearing the stagnation of pus in the wound, passed a drainage-tube between the flaps, leaving the two ends hanging out between the layers of cotton; through this tube he injected several times carbolized lotions, and as the tubes were often stopped up, the injection remained, in part, and after a few days—it was in mid-summer—the odor around the bed was very noisome; but M. Gosselin did not remove the dressing until the fifteenth day. In the interval the temperature had always been moderate, and the patient did not at all suffer. The wound was found suppurating, but the cicatrization had already commenced at the base of the flaps. The complete union in this case was very slow with the carbolized dressing, which M. Gosselin preferred to applying the cotton dressing a second time. It is but just to say that this patient was operated on on account of a white swelling of the femoro-tibial articulation, and that he succumbed shortly afterwards to tuberculosis.

During the vacation, when acting as externe with M. Berger, who replaced M. Gosselin, we saw him apply this dressing frequently, but after the manner of M. Guérin, and leaving it in place also, like him, for about thirty days, without changing, in two cases of amputation: the first, of the forearm, the carpal articulations having been opened by the bite of a horse; the second, of the leg, for prolonged suppuration from the carpal articulations of the foot. In both cases the result was excellent; the fever very moderate; the suffering so little that we saw the first patient walking about, a week or two afterwards, with

his arm in a sling. Both the patients were discharged convalescent, without having suffered from any complication.

M. Verneuil, in his lecture the 17th December, having just applied the apparatus in a case of suppurating arthritis of the wrist-joint, recalled his experience of it in cases of a similar nature. He remarked that its application in arthritis was not at all new; that it differed very little from the apparatus of Burgræve, employed very often by Nélaton (Thèse du Dr. Pilate, "De la compression dans les tumeurs blanches," Thèses de Paris, 1805). In the first case of hospital practice to which M. Verneuil had applied this dressing the result was very striking. It was in a case of suppurating arthritis of the wrist which had lasted eight months; every means was tried—injections with tr. iode., with permanganat. potassæ—but without the slightest amelioration; hectic fever set in; the temperature was at 39–40 (Centigrade) in the evening; and the patient, fearing to die in the hospital, wished to return home, when M. Verneuil, who had just had a success in a similar case in his private practice, applied the apparatus with splints to insure perfect immobility. Three days after this application the temperature had fallen to 37–38 (C.), the pain had entirely disappeared, and, after renewing the dressing twice during fifteen days, the patient was enabled to return home, coming at intervals of fifteen days for the renewal of the dressing; and after two months nothing more was seen of her. In another case, shortly afterwards, the effect was not less remarkable. It was a young man, already phthisical, who had been confined during three months previously in a prison-cell, and who was brought into the service with suppuration around the tibio-tarsal articulation and in the synovial sheaths of the tendons of the posterior muscles of the leg, with retraction of these tendons. At his entrance hectic fever had already set in; the anorexia was complete; the patient became day by day more feeble, and amputation seemed to offer the only chance of saving his life. M. Verneuil, however, encouraged by the other cases, applied the dressing, and the effect surpassed his expectation; after six days the fever had disappeared, and there was much less suppuration; in three months the patient was considered convalescent, and the retraction of the muscles had entirely disappeared. M. Verneuil has had the same result several times since; but in one case, though the dressing produced at each application an amelioration, the suppuration did not cease, and amputation was found necessary. A somewhat similar case occurred in the service of M. Alphonse Guérin. Those who wish to study the subject farther than the limits of this note will allow us can consult with first the thesis of M. Harvey, Thèse, Paris, 1871: "Applications de l'ouate à la conservation des membres et des blessés," thesis crowned by the Société de Chirurgie of Paris; and also the thesis of M. Blanc: "Pansements ouatés dans les arthrites suppurées," in which they will find at length the two cases of M. Verneuil that I have mentioned.

DANGERS OF VULCANIZED RUBBER NIPPLES.—Dr. Forestier, of Lyons, reports two cases of poisoning in young infants brought up by hand, both of which were probably due to the employment of white vulcanized rubber nipples. The symptoms were analogous to those of poisoning by the sulphide of carbon, and as that substance is employed in the vulcanization of the rubber, it was in all probability the cause of the accidents. One of the cases terminated fatally.

Progress of Medical Science.

SYPHILIS IN RELATION TO MARRIAGE.—Some very sensible rules in regard to this matter have been laid down by Dr. A. Fournier, in a lecture delivered at the Hôpital St. Louis.

There are three dangers which a syphilitic man causes by marrying: He may infect his wife, who will suffer not only from the disease, but from abortions; he may transmit the disease to his children; and he may, after marriage, be made deathly by the disease, or even incapacitated from supporting his family.

In view of these things, it is our duty to advise against marriage, except under special conditions. These conditions, which, if complied with, may make it tolerably safe to marry, are:

1st. Absence of actual manifestations of the disease.

2d. Advanced age of the disease.

3d. A period of immunity since the last outbreak.

4th. A non-menacing character of the disease.

5th. Adequate specific treatment.

The minimum time after infection should be three or four years, and the minimum time after the last outbreak should be eighteen months.—*Phil. Medical Times*, Jan. 4, 1879.

THE ELASTIC BANDAGE IN THE TREATMENT OF ANEURISMS.—It seems likely that Esmarch's bandage will add very greatly to our means of treating aneurisms. Dr. Weir has collected twenty-one cases of ilio-femoral, femoral, and popliteal aneurisms, mostly the latter, treated in this way. Twelve of these were successful, while the others failed, owing chiefly to the fact that obstruction to the arterial current was not kept up after the removal of the elastic bandage. Upon this point Dr. Weir lays great stress, and states that in it is the gist of the treatment.

In connection with the study of this matter, the question of how long a limb can be kept desanguinated is of importance. In the lower animals the time is six or eight hours. In man the time is longer than has been heretofore supposed. Ischemia has been enforced for four, five, and in one case fourteen hours without injury. During the compression it is important to remember that the arterial tension elsewhere is increased.

Autopsies have made it probable that coagulation begins in the tumor and extends up several inches into the artery. The arterial clot then becomes organized into fibrous tissue, and for this organization a healthy state of the wall is necessary. Aneurisms with large mouths are perhaps more easily cured by Esmarch's bandage.

As the result of a study of the cases collected, including his own, Dr. Weir recommends a plan of treatment like the following: the limb should be bandaged up to the tumor and above it, but not over it. The patient should stand erect before the upper bandage is put on. Tubing should be applied in the usual manner. The elastic compression may be kept on for two hours, followed by the application of a tourniquet for two hours. If pulsation is still apparent, the elastic and mechanical compression should be repeated until pulsation has ceased. After consolidation of the tumor is secured it is well to moderate the arterial current above the tumor for twelve or twenty-four hours by a bag containing seven or ten pounds of shot.—*Amer. Jour. Med. Science*, Jan., 1879.

COLLES'S FRACTURE.—In opposition to the position taken by Dr. Pilcher, Dr. J. S. Wight, of the Long Island College Hospital, maintains that fractures at the base of the radius are due to a combination of forces, of which the traction on the anterior ligament is but a small unit. In all cases, whether due to falls upon the palms, or to forced extension, three distinct forces may be distinguished: the extending power applied to the palm, the pressure of the radius upon the carpus, the resistance offered by the tendons and ligaments on the anterior of wrist-joint. These represent the forces of a lever, of which the fulcrum is the point of pressure of the radius upon the carpus; the long arm, the distance between the fulcrum and extending power in palm; the short arm, the distance between the fulcrum and the insertion of tendons, etc., on the anterior of joint. The pressure of the carpus upon the radius is equal to the sum of the other two forces, and must necessarily have a greater influence than either of them singly in the determination of a fracture. This is proved clinically by the fact that in a certain proportion of cases the line of fracture is between the fulcrum and the insertion of the ligament, whereas, if the fragment were pulled off by the ligament, the line of fracture should be beyond the ligamentous insertion. In one of the cases reported by Dr. Cameron, of Glasgow, the fragment was not completely separated, but was hinged anteriorly, and firmly impacted posteriorly, which should not have been the case if Dr. Pilcher's ligament were the principal cause of the fracture. From his investigation on this subject, Dr. Wight has arrived at the following conclusions: A fracture at the base of the radius may be anywhere within one and a half inches of the lower articular surface; or it may consist of a chipping off of the posterior lip of the articular surface; the fracture may be transverse, oblique, vertical; it may be impacted or comminuted; it is generally caused by the reaction of the resisting surface on which the palm of the hand strikes at the time of the fall, the carpus being driven or pressed against the base of the radius; it may be caused by extension or flexion of the hand on the forearm; muscular contraction must be recognized as an associate cause of importance; an important element in the causation of this fracture is found in the structure of the bone, the seat and direction of the fracture being usually where there is least compact tissue. Special exception is taken to the assertion of Dr. Pilcher, that "the fracture never entails permanent disability," for clinical observation and post-mortem examinations show that there are, and must be, some cases of fracture at the base of the radius, which will inevitably result in permanent deformity and disability.—*The Medical and Surgical Reporter*, November 16th and 23d.

PATHOLOGY OF URETHRAL STRICTURE.—Dr. John H. Brinton presented to the Pathological Society of Philadelphia, six specimens of urethral stricture, accompanying them with short histories of the cases. The attention of the members was called to the manifold causes of death in the respective cases—to wit, inflammation of the prostatic plexus of veins, inflammation of the prostatic gland, and prostatic abscess, acute nephritis, pyelitis, multiple abscess of the kidney, extra-prostatic abscess, and tubercular deposits in the bladder and testicle. He remarked that while in most cases the autopsy sufficiently accounted for the fatal result, in the last case recorded, absolutely nothing was developed which threw any light on the

cause of the death. The man was operated upon, and in eighteen hours died; whether in consequence of the operation, or simply as a coincidence, it is impossible to say. The period at which death occurred after the operation varied from eighteen hours to thirty-seven days. Urethral fever was present to a greater or less degree in all these cases. His observations on the localities of stricture agreed in the main with those of Sir Henry Thompson. These conclusions were based on an analysis of 132 strictures in 100 cases.—*Medical Times*, December 7, 1878.

TREATMENT OF EARLY PHTHISIS.—In the treatment of early phthisis, attention to the stomach and bowels is scarcely of secondary importance to the treatment of night-sweats. When the tongue is covered with a thick fur it is useless, or nearly so, to give iron and cod-liver oil; for the tongue is the indicator of the state of the intestinal canal, and absorption through the thick layer of dead epithelium cells is well-nigh impossible. Special attention should be given to all drains, such as diarrhoea, or, in the female, leucorrhœa or menorrhagia. All intercurrent disease or accident should be attended to assiduously. Hæmoptysis not uncommonly ushers in the end of a case of phthisis, but, on the other hand, it is often one of the best forms of local bleeding, recovery setting in from that hour. As a matter of clinical experience, slight hæmoptysis in early apical consolidation is usually associated with constipation, and is relieved by acting upon the bowels. When this symptom is associated with cold hands and feet, and the contraction of the vessels of the systemic circulation leads to increased blood-pressure in the lesser or pulmonic circulation, it is well to put the patient to bed, with hot bottles to the extremities, and hot fluids to drink, so as to dilate the systemic vessels generally, and so relieve the pulmonic congestion. The effects of mechanical irritants upon the diseased lungs are not sufficiently appraised. The advantages of a sea voyage, or a residence in the country, are due as much to the fact that the injured lung is not irritated by particles respired along with the air, as to the beneficial effect of improving the general health. Hygienic and dietetic matters should be carefully considered. Proper ventilation and an abundance of out-door exercise are indispensable. The diet should be nutritious and easily assimilable; it should consist of meat-juice in any form, milk and farinaceous foods, and especially the different foods prepared for infants, which are mainly starch partially digested. Alcohol may be taken with the food to aid digestion, and a glass of sound wine or good malt liquor, at lunch and at supper, is often of service; but the constant sipping of alcohol is bad, and the port-wine treatment of phthisis is unjustifiable, where it is not a hollow mockery and the wine a vile adulteration. The use of an opiate linctus, "to be taken when the cough is troublesome," is often followed by the most disastrous consequences, loss of appetite and flesh, constipation, etc. Where the cough is very troublesome, bromide of potassium may be given as affecting reflex action favorably with a minimum of bad after-effects. Hydrobromic acid with spirits of chloroform is effective in relieving cough. When a history of syphilis is present the prognosis is not so grave, the disease being amenable to specific treatment.—*J. Milner Fothergill, M.D.: The Practitioner*, October, 1878.

MM. FAUVEL and N. Guéneau de Mussy are retired, on account of age, from the Hôtel-Dieu. Their successors are MM. Empis and Moutard-Martin.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, February 22, 1879.

OVER-CROWDED ASYLUMS.

It is not a very creditable fact that in spite of investigations, reports, large appropriations, and new and costly asylums for the insane, there is quite as much over-crowding in them now as ever. There are seven thousand lunatics in the New York institutions, and there are proper accommodations for about four thousand. New York city tolerates within its limits an asylum which is essentially unfit, both in location and arrangement, for the treatment of the insane, and which now contains nearly half as many again as it properly should. There have been housed on Blackwell's Island thirteen hundred patients in wards intended for nine hundred. The whole has of course been run by a political machine, assisted medically by such fresh graduates as could be induced to remain a few months for washing and board. And New York is a city whose tender charity does not allow a horse to fall to the ground except under humane conditions.

We are assured, in reports, that this is a very sentimental view of the question, and that everything possible is being done. On the contrary, we cannot discover the slightest evidence that there is to be any permanent relief from over-crowding or any better supply of attendants. The large asylums, to be sure, are increasing their capacity, and in another year will have several hundred more beds. But the insane are increasing also every year at the rate of three and a half per cent., and these new wings and refurbished garrets will soon be filled. In addition to this, the continual enlargement of these already large asylums is but aggravating the misproportions of what is already a deformity.

The Association of Superintendents of Insane Asylums long ago fixed the proper limit to the capacity of an asylum at 250 patients, and recommended 200 as a better maximum. The resolution establishing this limit has been frequently endorsed since. Right in the face of this, however, several large asylums

have been built at an extravagant expenditure, and these are now being further enlarged. Meanwhile the problem of the disposition of the insane remains unsolved, while that of their proper care and rational treatment is in a still more hopeless condition.

Fortunately, however, there seems to be developing a tendency which may lead to better things. There is a growing desire on the part of the counties to keep their own insane, caring for them in county asylums. Some such method as this could be made very effective, and we believe that the movement should be encouraged. If necessary, two or three counties could unite in common to build an asylum. In this way the insane could be easily reached and speedily treated. It is found that the per cent. of insane to the population near an asylum is about 1 to 1,000. But as one recedes, the ratio increases, until, at the farthest limits of its districts, the proportion is 1 to 18,000. This shows either that insane asylums are contagious, or that lunatics at a distance do not get treatment. We assume the latter inference, and believe that by a system of smaller asylums, every one could be cared for.

To the objection of a possible increased expense we can say, first, that it is the part of humanity to care for the poor and sick in the best manner possible, and this should be our greatest consideration. On the other hand there might be no increase, but even a decrease in expenditure. Up to a certain point, the large hospitals are more economical; but there is a limit to this, and the very large ones do not save money proportionately. Besides this, with smaller hospitals the cost of transportation will be saved and the increased number of cures from early and judicious treatment will save the great expense of a long life of chronic insanity.

It would be easy, also, to combine a county hospital with the asylum; and the pauper sick, who are now treated by the poorhouse doctor at the regular fees, could receive the best treatment in these hospitals without charge. It is difficult to believe that with the reproach of the present system clearly before the public, some movement in this direction will not soon be inaugurated.

MEDICAL ETIQUETTE.

THERE is nothing which is so little understood by the public as the principles upon which medical etiquette is founded. As a consequence the prejudice against the very name is something almost ridiculous. When an anxious patient broaches the idea of calling in another physician, or of asking for a change in medical advisers, he, half in pity and half in fear, apologizes for interfering with professional rules, at the same time he smiles at their absurdity. There is something to him so unintelligible concerning the whole matter of interprofessional dealing, that he is only constrained by courtesy or politeness to countenance what he be-

lieves to be the merest whim. If the patient is anxious to retain his medical adviser, and consultation with some other practitioner is declined, he is very apt to protest in something like this form: "Well, doctor! If I understand you in regard to this medical etiquette, you would rather allow the patient to die than to transgress this arbitrary and unreasonable law." And too often the physician smiles, shrugs his shoulders, and conveys the impression that he would like to oblige the patient's friends if he dared to do so. The truth of it is, the physician has not the requisite amount of moral courage or professional honor to explain the course he takes. Here we think is the root of the difficulty and the real explanation for the undisguised derision with which the public estimate our conventional rules. It supposes them to be arbitrary, unreasonable, and positively detrimental to the best interests of the sick. How can we expect the contrary opinion to prevail under the present circumstances?

Besides the men who appear to be ashamed of the profession to which they belong, there are others who are so constantly straining a point in favor of the code as to make it and themselves ridiculous. The extremists on both sides of the question do the damage. If both would meet upon the common platform of the good of the patient, no one could be dissatisfied. And after all is this not the sole object of all medical etiquette? If it is not, it certainly ought to be. None but mean spirits can take advantage of the situation.

The physician who has the real good of his patient at stake can always act consistently with the code and be on the safe side. If he is afraid or ashamed to explain the point to the sick one, he is either unworthy of the trust placed in him, or he cowardly binds himself to rules which as a free moral agent he secretly despises. Provisions are made in the code for all sorts of emergencies of apparent interferences, so that there is but little if any chance for erring on any other side than that of humanity or common-sense. But how easy it is to explain this to the interested parties and assure them that consultations in the regular way are always the best for the patient, that a full, free, and manly interchange of professional opinion gives him the best chance of having his case thoroughly understood in all its aspects, past and future, gives the best possible assurance against useless repetition of drugs, and the best promise for rational progress in treatment. How few physicians take the trouble to do this, and how often does the profession suffer in consequence.

MEDICAL BOTANY.

OF the utility of botany to the medical profession as a body there can be no more question than of its utter neglect by the great majority of the profession in this country. When we state that very few medi-

cal men know anything whatever of the botanical characters of the plants employed in medicine, we state a fact which does not redound to the credit of our profession. It is not so in Europe; it was not so here fifty years ago. In the earlier part of the present century botany was taught in the medical schools, and we are mainly indebted to the teachings of those days for our present knowledge of the North American flora. The study of botany gave impetus to original research in the path of therapeutics, as it would unquestionably again, if pursued in our medical schools. The works on medical botany, published from thirty to sixty years ago, as, for instance, Barton, Bigelow, and Rafinesque, long out of print, and rarely seen, are full of valuable and suggestive information. During the past twenty-five years no distinctively American work on this subject has appeared, and those of foreign issue have had but limited circulation in this country.

For this neglect of a science at once so valuable and so necessary to medicine, the medical schools are mainly responsible. True, the lecturer on *materia medica* still glibly runs over the botanical description of a plant whose medicinal action is under consideration, but he speaks in a tongue quite unknown to nineteen-twentieths of the young men before him. The candidate for graduation is expected to know nothing of botany, and, in truth, he rarely disappoints that expectation.

Is it not about time to change this order of things? If our medical schools are not ready to take such an advanced position as to make some knowledge of botany one of the *requirements* for graduation, will they not at least furnish facilities for its *optional* study? At present the medical student who has not enjoyed the advantages of a college education, has absolutely no chance to learn anything of the science, except by getting a text-book and working it out himself—a process seldom employed. As generally taught in seminaries and academies—when taught at all—it is made as dull and uninteresting as possible, while it might be made extremely fascinating.

The principles of botany are not difficult of attainment, nor would the average student need to spend a great length of time upon it to enable him to identify most of our medicinal plants.

One objection which may be made to the re-introduction of botany into the medical course—that the student has already more than he can attend to—may be answered as all objections to a higher medical education are—*lengthen the course*. Another might be urged, which 'tis hardly worth while to answer—that he who wishes to experiment with our medicinal plants can do so as well without a knowledge of their botanical character as with it. The common names of plants are totally unreliable, the same plant being known by perhaps a dozen different names in as many different localities; and, again, plants appearing

identical to the casual observer are frequently decidedly different, and possessing widely different qualities. Numerous illustrations might be offered in support of this statement were it deemed necessary.

Were the experiment made of teaching botany, say, in the summer course of lectures, when fresh plants can readily be obtained for demonstration, we are sure the result would be not only gratifying, but valuable. And when we have a body of men duly qualified to experiment with our indigenous plants in the fresh state, conducting their experiments with the accurate methods now in vogue, we shall doubtless see many potent and valuable remedies, now entirely in the hands of Homœopaths, Eclectics, and Herbalists, elevated to positions of confidence and esteem in our own materia medica, instead of being briefly described in fine print in the secondary list of the U. S. Dispensatory.

Reports of Societies.

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, January 6, 1879.

DR. J. C. SHAW, PRESIDENT, IN THE CHAIR.

CHRONIC MYELITIS OF THE ANTERIOR HORNS, WITH LATERAL SCLEROSIS. (CASE OF PROGRESSIVE MUSCULAR ATROPHY.)

DR. J. C. SHAW exhibited microscopic specimens illustrating changes in the spinal cord as above mentioned, and gave the history of the case with comments.

ORGANOLOGY OF THE ISLAND OF REIL.

DR. E. C. SPITZKA made a brief communication upon the above subject, and exhibited the brain of several animals.

He stated that, in order to test Brown-Séguard's proposition—that if there existed psychomotor centres in the cerebral cortex, these should be located in the homologous gyri of different animal species—he had examined and compared the relative dimensions of the island of Reil in a large series of animals, including the elephant, hippopotamus, horse, lion, chimpanzæ, orang-outang, several species of rare monkeys, and the seal. He further stated that the statement made in comparative anatomical and physiological text-books—that man was the only animal possessing an island of Reil, completely covered by overlapping convolutions—was erroneous, as the island of the elephant and the anthropoid apes was as completely covered. He found that in an ascending series, beginning with the carnivora and passing through the monkey tribe to man, the island exhibited a perfect parallelism in development with the development and complexity of co-ordinations manifested by the muscles of the larynx, face, tongue, and fingers. It therefore followed that these peripheries found their central projection in and about the island in those animals.

But, on comparing herewith the ungulates, such as the hippopotamus, it appeared that the same area might undergo an exuberant development, even though the peripheries in question were rudimentary. A

single instance like that, he believed, overthrew Brown-Séguard's proposition; and equally the objection to the experiments of Hitzig, which Brown-Séguard based on this (perfectly gratuitous) assumption, fell to the ground.

DR. W. A. HAMMOND referred to the history of a case which had some pathological relation to the paper read by Dr. Spitzka.

A male patient had right hemiplegia, and absolutely complete aphasia. The clinical history was that of rheumatism, endocarditis, and embolism. Diagnosis of embolism of the middle cerebral artery was made. An unfavorable prognosis was given. Dr. Hammond thought he might improve somewhat with reference to his motor power, but that there would never be any improvement in the faculty of speech, and that he might die very soon.

It was in the spring of 1871 that he saw the patient. A few days ago he received a letter from the attending physician, who informed him that the prognosis which he had given was absolutely faulty in every respect, for the patient was not only alive, but he had not improved in the slightest degree with respect to motor power, although he was able to speak very well, and had acquired a vocabulary of about 500 words within six months.

Such recovery of the power of speech, after the development of complete aphasia, was unique in Dr. Hammond's experience, and it was for the purpose of obtaining an explanation that he related the case. He had seen cases in which persistent effort had been made to instruct aphasic patients, but the progress was so slight that the effort was abandoned. The only explanation which usually would be given was that the opposite side of the brain came to preside over speech.

DR. SPITZKA referred to reported cases in which persons with right hemiplegia and aphasia had learned to write with the left hand, thus showing education of the other side of the brain.

DR. HAMMOND thought that the improvement should have been more gradual, if such was the real explanation.

DR. SEGUIN remarked that he had seen cases of infantile aphasia, in which subsequently the patient talked as well as any one.

Special mention was made of one case in which right hemiplegia, and contraction, and imperfect development of the limbs still existed; yet the girl talked perfectly well, although the aphasia continued complete for a long time.

The explanation that the right speech-tract assumed the faculty of the left, was the one naturally given.

DR. HAMMOND remarked that it was difficult to conceive of such an education in the adult brain.

DR. SEGUIN remarked that the comparatively sudden return of speech might be explained in accordance with the law of development of speech in children; some children came out with quite a vocabulary of words in the course of a few weeks.

DR. HAMMOND remarked that the cases were not analogous, because in one instance the brain was undergoing development, while in the other it was not.

DR. GREY referred to a case, reported by an English writer, similar to that reported by Dr. Hammond. There was a history of right hemiplegia with aphasia lasting for some time, but after the expiration of several months the aphasia nearly disappeared. At post-mortem the entire third frontal convolution and parts surrounding the island of Reil upon the left side were found destroyed, v. on the right side

of the brain corresponding portions were perfectly healthy. In that case there must have been a transfer of function from the left to the right side of the brain.

DR. SPITZKA referred to a case reported by a Swedish writer. A dragoon received, upon the left frontal protuberance, a kick from a horse. He was delirious shortly before death, but neither before delirium developed, nor while it was present, was there any symptom whatever of aphasia. At autopsy there was found complete destruction of the island of Reil upon the left side of the brain and all the parts surrounding it; the right island of Reil, the right hypertriculum, and the right anterior convolution were nearly all that remained of healthy brain-tissue in the anterior lobes.

DR. GREY suggested that recovery in some cases of aphasia might be due to re-establishment of circulation in the convolutions through some of the anastomosing branches of the middle cerebral artery.

THE DIFFERENTIAL DIAGNOSIS OF NEURASTHENIA— NERVOUS EXHAUSTION.

DR. G. M. BEARD read a paper upon the above subject, which may be summarized as follows: Although neurasthenia was more common in this country than any other form of nervous disease, as yet it had been only slightly studied. The condition to which the term was applied had long been known among the people, and to a certain extent among the profession, under such terms as general debility, nervous debility, spinal weakness, and more accurately and recently by some special symptoms, such as spinal irritation, nervous dyspepsia, cerebral and spinal anæmia and hyperæmia, irritable ovary, irritable uterus, uterine asthenopia (Knapp's term), and sexual exhaustion.

His first paper upon the subject was prepared in 1863, read before the New York Medical Journal Association, and published in the *Boston Medical and Surgical Journal* for April 29, 1869. It subsequently appeared in the first edition of Beard and Rockwell's work upon electricity. That paper was based upon the study of thirty cases. For five years the subject excited but very little attention, but during the last five years a number of writers had treated the subject incidentally, if not elaborately. Among those were Hugh Campbell, of London, who issued a work upon the subject, which amounted in fact to a republication; Dr. Jewell, of Chicago, Dr. Mitchell, of Philadelphia, and also Dr. Goodell, of Philadelphia, in his recent address upon neurasthenia and womb tire, read before the American Gynecological Society. Of late, however, the subject had been studied most systematically and scientifically by Erb, of Heidelberg, who had a chapter on neurasthenia in Vol. XIII. of Ziemssen's *Cyclopædia*. In that chapter Erb had confirmed the description and analysis of neurasthenia which Dr. Beard had given in 1868, and had added some judicious and valuable observations of his own.

Originally the term neurasthenia included all types of nervous exhaustion; the symptoms coming from the brain and the symptoms coming from the spinal cord. During the last five years he had differentiated the symptoms coming specially from the spinal cord as *myelasthenia*, and those coming from the brain as *cerebrasthenia*. Erb did not make such distinction, but followed, in general, the description given in his original paper. Dr. Beard regarded it as quite important to make a differential diagnosis between myelasthenia and cerebrasthenia, for the hygiene and the treatment of the two conditions was quite differ-

SYMPTOMS OF CEREBRASTHENIA, OR EXHAUSTION OF THE BRAIN.

The symptoms of cerebrasthenia or exhaustion of the brain were: tenderness of the scalp; a feeling of fullness in the ears and head; vertigo; tenderness of the gums; fluctuating disorders of the special senses, such as a morbid subjective smell, noises in the ears, flashes of light before the eyes, *musca volitantes*; morbid desire for stimulants and narcotics; deficient thirst; gaping, yawning; congestion of the conjunctiva; tendency to shed tears; mental depression; impairment of memory and intellectual control.

MYELASTHENIA, OR SPINAL EXHAUSTION.

The symptoms which suggested myelasthenia, or spinal exhaustion, were: local spasms of muscles; local chills and flashes of heat; shooting pains in the limbs; startings and jerkings on falling to sleep; morbid sensations at the bottoms of the feet, as burning or tenderness, vague pains in the feet, podalgia; sexual debility in its various phases; pains in the back, any part of it from the nape of the neck to the tip of the coccyx, with or without the accompaniment of spinal irritation; creeping and crawling sensations up and down the spine; incontinence of urine, paresis of the bladder; feeling of pressure in the chest, with or without ticklishness in that region; heaviness and stiffness of the muscles, simulating rheumatism; great sensitiveness to cold and changes in the weather; hyperæsthesia of mucous membranes, as of the throat, urethra, or larynx; morbid dryness of the skin, or morbid perspiration; dryness of the joints; dilated pupils. There were certain other symptoms, such as nervous dyspepsia, constipation, flatulence, sick headache in all its phases, numbness, hyperæsthesia, insomnia, which manifested themselves both in connection with cerebrasthenia or brain-exhaustion, and myelasthenia or spinal exhaustion.

In myelasthenia, or spinal exhaustion, physical exercise, especially walking, and standing, made the patient worse, and brought on pain in the back.

In cerebrasthenia, or brain-exhaustion, severe, violent and long-continued muscular exertion could oftentimes be well borne. Hence the practical rule of treatment, that in cerebral exhaustion—cerebrasthenia—active muscular exercise in reasonable amount might be allowed and enjoined; while in spinal exhaustion—myelasthenia—relative rest, in some cases absolute rest or only passive exercise, was demanded. A neglect of that distinction was the source of much error in practice, as verified by his experience, for he constantly saw patients who had been advised to exercise, but who should rest; and advised to rest, who should exercise.

NEURASTHENIA AND ORGANIC DISEASE.

Dr. Beard regarded it important to make a differential diagnosis between neurasthenia and organic or structural disease of the brain or spinal cord. He had been frequently consulted by physicians with reference to themselves for symptoms which were supposed to indicate ataxia or some form of organic disease of the spine or brain, when in reality they only had symptoms of neurasthenia. Some of those medical men were greatly alarmed, and the more they read upon the subject, in German authorities, the more alarmed they were, for in our literature the distinction between neurasthenia and symptoms of organic trouble were not clearly made out.

FOUR POINTS OF DIFFERENTIAL DIAGNOSIS BETWEEN NEURASTHENIA AND ORGANIC DISEASE OF THE BRAIN AND SPINAL CORD.

There were four points in the differential diagnosis of neurasthenia from organic disease:

1. The symptoms of organic disease were usually fixed and stable. Those of neurasthenia and allied states were fleeting, transient, fluctuating, metastatic, recurrent, intermittent.

2. There were certain symptoms of neurasthenia which did not usually appear in organic or structural disease. Of those, mention was made of general or local itching without apparent cutaneous disease; tenderness of the teeth and gums; special idiosyncrasies with regard to food and medicine, which did not exist prior to the illness; morbid desire for stimulants and narcotics; morbid fear in its different phases, agoraphobia (fear of places), astrophobia (fear of lightning), antropophobia (fear of men); likewise sick headache.

3. In organic disease reflex activity was usually diminished, while in functional disease reflex activity was usually increased. To that rule there were some exceptions, as in spasmodic spinal paralysis.

4. Neurasthenia and allied troubles were most likely to occur in those in whom the nervous diathesis predominated.

The characteristics of the nervous diathesis he had frequently described in other writings.

Neurasthenia was to be distinguished from hypochondriasis or pathophobia, from hysteria, and from cerebral and spinal anemia and hyperemia.

In neurasthenia the anemia and hyperemia of the brain and spinal cord were results, symptoms, temporary, intermittent, and not the disease; and it was unphilosophical to call them the disease.

The same was true with reference to oxaluria, a condition often found in neurasthenia.

The doctrine that innervation preceded circulation was a growing one among neurologists. That point was urged in his original paper on neurasthenia. Vulpian's researches upon the physiology of sleep were in harmony with that view. Erb, in his chapter on neurasthenia, also leaned towards that view.

Neurasthenia was also to be distinguished from nervous syphilis, which it sometimes simulated in a wonderful way.

Neurasthenia also occasionally simulated in a perfect and interesting way the *symptoms of a common cold*. The chilliness, the positive coldness, the tremor, the heaviness, the soreness, the pain in the back and the limbs, and in some cases the excessive secretion from the eyes and nostrils, all made it hard to determine whether the patient had taken cold or not.

OVERDOSE OF ELECTRICITY.

An overdose of electricity upon a neurasthenic patient might bring on all the symptoms of a common cold, so that the patient might suppose he had taken cold.

Neurasthenia might simulate *rheumatism*.

DIFFERENTIAL DIAGNOSIS BETWEEN NEURASTHENIA AND ANEMIA.

Neurasthenia was to be distinguished from anemia mainly by the following symptoms:

Neurasthenia was found chiefly in connection with the nervous diathesis; the patient might be plethoric; the pulse might be full and normal; no cardiac murmurs, no pallor; was common to both sexes, but not so relatively frequent in females; was benefited by remedies which directly affected the nervous system,

iron alone being of but little service; recovery was gradual, and occurred chiefly between the ages of fifteen and sixty.

Anæmia, on the other hand, appeared always with the tuberculous, the rheumatic, or other diathesis; was marked by increase of the watery constituents of the blood and diminution of red blood-corpuscles; was found in all periods of life from infancy to old age; was accompanied by small, weak pulse, cardiac murmurs, pallor of the face and lips, less mental depression than was present in neurasthenia; occurred relatively more frequently in females than in males, might be rapidly cured by removal of the cause, and was benefited by iron alone.

The two conditions, anæmia and neurasthenia, were sometimes associated in the same patient.

DIFFERENTIAL DIAGNOSIS BETWEEN NEURASTHENIA AND HYSTERIA.

These two diseases were oftentimes confounded with each other. In hysteria there were usually convulsions, paroxysms, *globus hystericus*, anesthesia of the epiglottis, ovarian tenderness, attack of general and local anesthesia, a certain acuteness, intensity, and violence of the symptoms; was usually associated with great emotional activity; occurred most frequently in non-balanced mental organizations, and was comparatively rare in males. In the mental or psychical form it occurred with perfect physical health. Recovery might be sudden under purely emotional treatment.

In neurasthenia, on the other hand, there were no convulsions or paroxysms; no *globus hystericus*, no anesthesia of the epiglottis; there might be ovarian tenderness, often was, but it was not so common as in hysteria; the attacks of local or general anesthesia were not so common; the symptoms were more moderate, quiet, subdued, passive; often occurred in well-balanced intellectual organizations; very common in males; always associated with physical debility; recovery was never sudden, but always gradual.

Dr. Beard agreed with Erb that the disease needed a more systematic and careful study than it had received. It was very common, was increasing in frequency, and was the cause of a great deal of real distress. He then read the history of a number of cases which illustrated the symptoms mentioned. In some of those the diagnosis of ataxia had been made.

The Society then adjourned.

WEST CHICAGO MEDICAL SOCIETY.

Regular Meeting, December 9, 1878.

THE PRESIDENT, DR. BRIDOE, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

LUMBO-COLOTOMY FOR CANCER OF THE RECTUM.

DR. J. H. SALISBURY read the history of a case that had recently occurred in Cook County Hospital. The patient was an English sailor, thirty-five years old. He had passed blood and slime with his stools for two years; had been in hospital at Buffalo for "chronic diarrhoea," and, within a year, had been in the Marine Hospital at Chicago, where the true character of his trouble was discovered. From a year before his death he had frequent pain in the rectum. After leaving the latter hospital he took injections of carbolic acid and glycerine, which apparently gave him some comfort. He came into Cook County Hospital July 9, 1878. For a week he had had anorexia and swelling, and

more pain in the abdomen, and the dejections of slime and blood were frequent. He had lost fifty pounds in weight in two years. The rectum was obstructed by a projecting, hard, cancerous mass; the opening through or past this mass was so small a catheter would not pass. No faecal evacuation had taken place for nine days. The necessity being pressing to give the man some relief from the suffering due to the faecal accumulation, Professor Gunn, on July 15th, performed colotomy. An incision five inches long was made through the abdominal wall, "running from a point two inches above the anterior third of the iliac crest, obliquely upwards and backwards." On the colon being exposed, two ligatures were passed around it, and the gut divided between them. The cut ends were then stitched to the external opening. Recovery from the operation was prompt. Thereafter faecal matter was regularly passed through the artificial opening, and there was no longer suffering from any accumulation. A month later the patient began to pass more blood and slime, with some shreds of tissue by the rectum, and to have more pain. He died of exhaustion November 11th. Two weeks before death œdema of the left leg came on. From October 18th there had been difficulty in passing urine, and the quantity of the fluid had been scanty.

At the autopsy it was found that the whole peritoneal surface was covered with "thousands of fine, white, cancerous nodules, varying in size from that of a mere dot to that of a pea." The artificial anus was found to open into the colon at a point not covered by peritonem. The rectum and sigmoid flexure were greatly distended with cancerous infiltration; indeed the latter was everywhere throughout the pelvis. The pelves of the kidneys were distended, and the kidneys enlarged from hydronephrosis. The openings of the ureters into the bladder were closed by cancerous infiltration. The specimen was exhibited.

A discussion of the case and of the subject of colotomy for relief of intestinal obstruction then ensued, in which several members took part.

Dr. SALISBURY remarked upon the easy recovery from the operation in this case, and the great relief from distressing symptoms which the patient enjoyed afterward. Death must have ensued within a very few days if the operation had not been performed.

Regular Meeting, January 13, 1879.

THE PRESIDENT IN THE CHAIR.

Dr. E. L. HOLMES read the report of a case of tubercle of the choroid in a case of general miliary tuberculosis. The specimen was found in a post-mortem examination made by Dr. Chr. Fenger at the County Hospital. Dr. H. thought this was the first instance in the North-west where a physician at an autopsy had examined the eye for tubercle of the choroid to verify the clinical fact that the choroid is often involved in acute miliary tuberculosis.

The patient was moribund when brought to the hospital, and no history could be procured. Nearly every organ of the body was infiltrated with miliary tubercle. The man was apparently about thirty-five years old. Eight miliary tubercles, perceptible to the naked eye, were found in the posterior half of the choroid.

The choroid was, he said, a favorite locality for the development of miliary tubercles. These bodies would vary in size from one-third to two and one-half millimeters in diameter, and they were usually deposited upon the posterior portion of the choroid,

so that they might be perceived by the aid of the ophthalmoscope during life. In cases of deposit of cheesy masses in the lungs and abdomen, tubercles would not be found in the choroid. If tubercles are discovered in the choroid it was nearly certain they would be found elsewhere in the body. So far as records state, there were no subjective symptoms produced by tubercles in the choroid. Theoretically there should be distorted vision.

Dr. W. T. MONTGOMERY asked if careful observations had been made to test the sight of patients with tubercle of the choroid.

Dr. HOLMES replied that he thought not. The patients had been generally too young—as children with tubercular meningitis—or they were, if adults, too near death when the tubercles had been discovered in the eye to make careful tests of the sight very likely or even possible to be made.

The question of the relation of miliary and yellow tubercle to each other being raised by a member,

Dr. W. T. BELFIELD remarked that it was held by some of the later pathologists that miliary tubercle was due to the absorption of caseous matter from a deposit of this material somewhere in the body following an inflammation. The older view, still held by some, had been that the yellow is always due to a degeneration of the gray tubercle.

Dr. H. M. LYMAN said he did not think those who claimed miliary tubercle was due to the infection of the system by caseous matter had proven their point. It was a plausible theory, and had some facts that might look in its favor. But that caseous matter was found in the dead body, surrounded by a plentiful crop of miliary tubercles, did not prove the point, for the cheesy substance itself might have been preceded by miliary deposits, of which it was the rapid degeneration. In that case both kinds of material would be due to one and the same cause. It was almost never possible to say positively that caseous matter deposited in the midst of a mass of inflamed tissue had not been preceded by a rapid deposit of miliary tubercle that as rapidly had gone into degeneration. Degenerative changes often went on in a diseased body very rapidly, and made parts appear very differently which had been alike, and he thought we should be cautious how we attributed one morbid condition to the effect of another.

The subject was further discussed by Dr. L. H. HORCOURT, the President, and others.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 8, 1879.

Dr. J. C. PETERS, PRESIDENT, IN THE CHAIR.

LUMBO-COLOMOTY—INTRACTABLE STRICTURE OF THE RECTUM.

Dr. J. W. HOWE exhibited a patient upon whom he had performed the operation for lumbo-colotomy, four years previously, and gave the following history of the case:

Rosa Nott, aged 51, was admitted to St. Francis' Hospital, February 23, 1875. For a period of twelve years she had suffered great pain on defecation, and was compelled to use injections and cathartics to procure a movement from the bowels. Pus and blood were often mixed with the fecal matter. Two operations, the nature of which was unknown, had been performed before she came to the hospital. Upon examination, the rectum was found to be occupied

by large ridges and bands of fibrous tissue, between which were deep and irregular ulcers. The index-finger could be passed into the rectum about three inches. At this point the stricture was much smaller, and the tip of the finger could not enter. The vagina was also closed by fibrous adhesions. The patient was in constant pain. No movement could be had without the use of oil and warm water injections. Blood and mucus were always mixed with the fecal matter. The patient was very much emaciated, and unable to move about. Attempts were made to heal the ulcers and dilate the stricture, but without avail. As it was evident that the woman was sinking rapidly, the descending colon was opened by an oblique incision, four inches in length, extending from the lower border of the last rib downward and forward two inches beyond the centre of the iliac crest. The gut was reached without difficulty, though an attempt was made to distend it by injecting air or water. The edges of the wound in the intestine were united to the integument in the usual manner, and a piece of wax candle with a ligature through its centre, was inserted and fastened in the opening to prevent prolapse. Two very large and fetid evacuations took place through the false anus within six hours after the operation. The relief afforded was complete, and though an attack of erysipelas retarded the healing of the wound, recovery was complete in two months, and the patient left the hospital in excellent condition. For two years afterwards the patient suffered some inconvenience from prolapse of the gut. Small quantities of fecal matter passed through the rectum as well as through the false anus.

A period of twelve months has now elapsed without the slightest prolapse. The rectum has been completely closed, and all the fecal matter has been evacuated for the past six months through the opening in the colon. The general health of the patient is good, she is free from pain, and is able to work fourteen hours each day, making pants at fifty cents per pair.]

OSTEOPHYTIC RIB.

DR. S. CARO presented a rib, with osteophyte attached, removed from an Italian slave who died on Blackwell's Island of pneumonia of left lung. The exostotic growth was in the situation of a previous fracture of the bone, and the two circumstances appeared to be related to each other as cause and effect.

ULCERATION OF INTESTINE IN THE THIRD WEEK OF TYPHOID.

DR. BEVERLEY ROBINSON presented a specimen of intestine removed from a man who died of typhoid fever in the third week of the disease. The points of interest were the existence of intestinal lesions at that period, and without diarrhoea, also a degeneration of the muscular coats of the ileum at different points.

ARTICULAR OSTITIS—CURIOUS CURVATURE OF LOWER END OF FEMUR—AMPUTATION.

DR. KEYES presented the lower end of the femur with the knee-joint, tibia, etc., taken by amputation from a boy of eleven years. The patient had sinuses, which had existed a long time between the hamstring tendons and above the knee in front, all leading to a movable sequestrum in the lower end of the femur. Abscesses had existed so long in this region that the customary deformity had occurred by contraction of the posterior muscles of the thigh, namely: flexion of the leg upon the thigh, as if by the customary partial backward dislocation of the knee. The knee-joint

had never shown signs of inflammation, but appeared to be the seat of fibrous ankylosis.

Dr. Keyes, with Dr. Van Buren in consultation, removed the sequestrum from the lower end of the femur posteriorly. Then, recognizing that the shaft of the femur at its lower end with the involucrum were curved, so that the articular surface of the lower end of the femur looked nearly backwards, he extended the leg and cracked the involucrum, hoping thus to straighten the limb. The attempt, however, proved ineffective.

The patient did badly after his operation, and a continuance of the contraction of the hamstring muscles increased the curvature of the lower end of the femur so that amputation in the middle third was decided upon. The operation was done with long anterior flap. The patient made a good recovery.

The specimen was exhibited to show the curious effect of the constant contraction of the hamstring muscles upon the softened and inflamed bone and involucrum, at the lower end of the femur above the line of epiphyseal cartilage, which was clearly evident in the line of section of the bone, between the condyles.

The curvature of the femur was so great that the axis of the centre of the articular surfaces of the condyles was thrown backwards, nearly 45° from the natural direction. There was very little posterior dislocation of the tibia, the deformity customarily due to this dislocation having been produced by the above-mentioned posterior curvature of the femur.

Dr. Keyes alluded to an article by Volkmann (*Berliner klinische Wochenschrift*, No. 50, Dec. 14, 1874, p. 629, with woodcut, a copy of which was produced), wherein it is claimed that in cases of inflammatory disease about the knee-joint, where contraction of the posterior muscles occurred, the tibia was drawn away from the articular end of the femur, and consequently the condyles, relieved from the accustomed pressure of the tibia, grew forward in an egg-shaped manner, while the lateral ligaments became relatively posterior in the joint, making reduction mechanically impossible without rupture of both lateral ligaments.

This condition, which it was claimed obtained in all cases, was shown by Dr. Keyes's specimen to be not uniform. The continued action of the hamstring muscles is capable of twisting backwards the whole knee-joint, and with it the lower end of the femur, provided the bone be inflamed and softened above the line of the epiphyseal cartilage. No egg-shaped prolongation of the condyles forward was present in this case.

MICROSCOPIC ANATOMY OF THE HUMAN TEETH.

DR. C. HEITZMANN presented microscopic specimens of human teeth, both in normal and curious conditions, and remarked as follows: The study of the minute anatomy of the teeth was done last year by C. F. W. Bödecker, in my laboratory, and the results obtained may be considered as a new departure in odontology. Nobody ever could have doubted that a tooth is alive as long as it is in close connection with the jaws; but all former examiners have failed in demonstrating the living matter, because of the wrong method applied, viz., grinding dry teeth. Through new methods B. succeeded in discovering: (1) that the dentical canaliculi contain fibres—first seen by Tomes—which are formations of living matter; these fibres are beaded, and send numerous lateral offshoots into the basis-sub-

stance between the canaliculi, where a minute network of living matter is established, the meshes being filled with glue-giving basis-substance, infiltrated with lime salts. (2) The enamel contains fibres of living matter between the rods, and the latter themselves are pierced by a network of living matter also. Between the rods are seen narrow interstices, invariably traversed by delicate thorns, the uniting threads of living matter. (3) The cementum is fully identical with bone; its laennæ hold protoplasm, the branching and uniting offshoots of which traverse the basis-substance, thus establishing a minute network of living matter throughout the whole basis-substance.

The process of caries of the teeth has been studied in my laboratory by Dr. Frank Abbott. The results are that caries is first a decalcification, afterwards a reduction of the tissues of the tooth, the dentine, enamel, and cementum, whereby the basis-substance is liquefied and medullary elements, the embryonal, forming bodies of the tissues simply reappear. No further new growth occurs from these elements; but they become disintegrated and replaced by a new growth of micrococci and leptothrix. These results are in full agreement with observations made by myself in avascular tissues, especially in cartilage, where the lesion, though produced by intensely irritating agents, viz., hot iron, did not lead to an inflammatory reaction, if cartilage was injured alone.

PERFORATING ULCER OF THE DUODENUM, AND SUDDEN DEATH.

DR. LOOMIS presented a specimen of perforating ulcer of the duodenum, removed from the body of a gentleman who died suddenly on the 21st of September, in the Chambers Street depot of elevated railroad. The Coroner gave the cause of death as heart disease. Four days after death, the body being on ice, Dr. Loomis was asked by the wife of the deceased to examine the latter and see if he was really dead. There was no doubt of death, but considerable doubt as to the cause of death. This fact was stated to the widow, and an autopsy was the result. The examination was made by Dr. Drake in presence of Drs. Loomis and G. A. Peters.

The deceased, for twenty years, had been the subject of severe attacks of gout, but rarely summoned a physician for relief. He had found that White's pills (calomel, aloes, ext. colchicum, and ipecae, each one grain) served his purpose. He never had any deformity of the joints, nor evidence of deposits within the joints. There was a slight deformity of the joint of great toe. With the foregoing exception he enjoyed good health until two years ago, when dyspeptic symptoms showed themselves. He accordingly consulted his family physician, who treated him for chronic gastric catarrh. He complained of pain in the epigastrium, especially after eating. He lost flesh quite rapidly. Last May he consulted Dr. Loomis for vertigo and palpitation. The heart was found moderately enlarged, but there were no valvular lesions. In consequence of the presence of dyspepsia, the loss of flesh, and a peculiar paleness of the skin, associated with the previous history, a diagnosis was made of gouty kidney, and the patient was recommended to spend the summer at the Hot Sulphur Springs. The urine was examined but once, and no casts nor albumen were found.

On the morning of the day of his death the patient was cheerful and ate a hearty breakfast, walking a distance of one block to the elevated road. Death appeared to take place instantly.

At the autopsy the cerebral sinuses were found engorged, the arteries at the base of the brain atheroma-

tous and diminished in calibre, with punctate extravasations in the neighborhood. No softening anywhere; lungs were normal. The left side of the heart was enlarged, the ventricular walls thickened, and the cavity of left ventricle slightly increased. The aorta was extensively atheromatous throughout, and its thoracic portion apparently considerably dilated. The kidneys were diminished in size, capsule adherent and thickened, showing gouty lesion in its early stage. The stomach was increased in size, and filled with undigested food. Its walls were considerably thickened, especially at its pyloric extremity. Its mucous membrane was pigmented, and one or two points were evidences of recent extravasations. The pyloric orifice was somewhat diminished in size. The commencing portion of the duodenum was thickened, and about an inch from its commencement there was an ulcer about the size of a twenty-cent piece and oval in shape, and at its bottom was a button-hole slit opening into the peritoneal cavity, and giving exit to a considerable quantity of digested material. The peritoneum, in the neighborhood of the perforation, was somewhat thickened, while the surrounding mucous membrane within the duodenum was denuded. The liver was normal in size and appearance, and the spleen was slightly enlarged. The cause of death was charged to the shock which occurred at the time of rupture. In conclusion, Dr. Loomis stated that perforating ulcer of the duodenum was not common.

DR. PETERS stated that but ten cases of this lesion appear in the records of the Society.

DR. LOOMIS remarked that one authority stated that but two cases of the sort were met with in thirty thousand autopsies.

DR. KEYES asked if the patient had suffered from syphilis, and being answered in the negative, referred to the following case:

A patient suffered from symptoms of syphiloma of rectum, which finally yielded to a prolonged mixed treatment. In the mean time he began to have gastrointestinal symptoms and intercurrent diarrhoea. For the purpose of being treated for the latter, he came from Philadelphia to this city. Immediately after arriving at the hotel he was seized with symptoms of collapse, from perforation of the gut, and died within twenty hours. He had black vomit ten or fifteen hours before death. At the autopsy the perforation was found in the upper part of the small intestine. Numerous pigmented cicatrices, throughout the small intestine, with adherent peritoneum, marked the site of previous ulcerations.

DR. PETERS referred to a case of very extensive ulceration of the colon, connected with gout. This condition had lasted for thirty years.

DR. LOOMIS did not think that the perforation in his case had anything to do directly with the gouty diathesis. He supposed that the ulcer was simply the result of obstructed circulation at that point. One peculiarity of the case was the suddenness of death.

DR. BRIDDON had a case which lived for twenty-four hours after perforation occurred.

DR. STIMSON presented a specimen of extra-capsular fracture of femur.

After which the Society went into Executive Session.

A MEDICO-LEGAL POINT.—DR. GÉLLÉ asserts that the tympanic cavity of a fetus at term is filled with a gelatinous fluid. If the child have breathed an hour or two the tympanum shall be found to contain air.—*Med. Press and Circular.*

Correspondence.

CONTINUOUS EXTENSION IN SPINAL CURVATURE—A QUESTION OF PRIORITY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the last number of your paper, in the report of the Stated Meeting of the Medical Society of the County of New York for January 27, 1879, Dr. John A. Wyeth read a paper upon "The Treatment of Spinal Curvature by Continuous Extension," and gave the history of an illustrative case. His apparatus consisted of a plaster-of-paris jacket made "in two segments which nearly came together at the point at which the lesion was situated."

Into each jacket, while it was being applied, were fastened perforated zinc plates, and in the centre of these were fastened strong iron staples, which were connected—the lower with the upper by ratched bars, which could be lengthened or shortened by a key. With such an apparatus, Dr. Wyeth states, that if extension and fixation were the indications, he thought they could be constantly maintained, etc., and, at the conclusion of the able discussion which followed, remarked that it was scarcely possible to found a dynasty with one subject, nor could he hope to establish a new principle in surgery upon a single success. With regard to the efficacy of the principle, I will say more when the proper opportunity comes for publishing the cases already treated, the question at present engaging me being one of *priority*.

I have no wish to rob Dr. Wyeth of any of the laurels which are laid at his feet as the discoverer "of a new principle in surgery;" but my object in writing to you to-day is to establish, beyond the question of a doubt, that Dr. Wyeth *was not* the first in the profession to establish this principle. The patient for whom Dr. Wyeth constructed his first splint, came "under his observation in April, 1878." Two solid plaster-of-paris jackets were applied, each consuming several weeks' time before the apparatus described above was put on; so that we may fairly deduce the latter part of May as the time for his first application of an apparatus for producing fixation and extension. This idea of combining immobility and extension in the treatment of disease of the lower part of the spine, occurred to me in January, 1878, about four months previous to Dr. Wyeth's application.

On January 10, 1878, I filed with Mr. Stohlmann, of the firm of Geo. Tiemann & Co., New York, a drawing of a plaster splint composed of two segments, one above and the other below, the seat of disease, held together by brackets composed of perforated zinc plates imbedded in the plaster and connected by ratched bridges to allow of *extension* and *fixation*. In February, 1878, I wrote out and illustrated myself a concise essay, applying this principle of extension, fixation, and exposure, to every joint of the body, including the intervertebral articulations, and submitted it to Drs. Ellsworth Elliot, Frank Kinnicutt, and Chas. McBurney, of New York, on the 15th of that month, as a competitive essay for the College of Physicians and Surgeon's Alumni Prize. This was not awarded, as the merits of the principle were not sufficiently tested to admit of its recognition by so high an authority. In no way altered or changed, the pamphlet, for so it soon became, was placed in the hands of Tiemann &

Co., the 6th of March, for publication, simply to establish priority for its principles. Experience now demonstrates this to have been a necessity, and the intention was to have given the journals articles from time to time when a sufficient number of cases were collated. This pamphlet comprises 22 pages, and is illustrated by 33 engravings, and was issued from the printer's before Dr. Wyeth began to apply the principle. It has had a large distribution, and I have the original manuscript which was submitted to the aforesaid doctors in February, and which has not been changed in the least by the printer.

From pages 2, 3, and 4, I clip the following paragraphs:

"ADJUSTABLE BRACKETS.—Zinc.—This is used in two forms. The first is short and broad (Fig. 1), of the thickness ordinarily used under stoves, etc., so

FIG. 1.

FIG. 2.

punched that the jagged edges of the perforations will be elevated above the surrounding surface, and thus allow the plastered bandage to hold it in place; and is used to form the terminal plates of the bracket, the special uses of which will be more fully detailed hereafter.

"The second form consists of long, narrow, thin strips, perforated, and is used when greater strength is required, as they hold the bandage, and are in turn held by the bandage so securely as to prevent displacement (see Fig. 2).

"RATCHES.—Either of two ratches may be inserted into the bridge for purposes of extension. The more simple is that devised by the writer, and consists of two overriding flat strips, provided with slots down the middle, in which two thumb-screws are placed to hold them together, as shown in Fig. 3. They can be so gradu-

FIG. 3.

FIG. 4.

ated as to indicate the amount of extension employed, and by the removal of one of the screws a false joint is produced, which may be placed at any point along the slot.

"The second ratchet was devised by Mr. F. A. Stohlmann, and is exact without being complex. It consists of two overriding flat strips, each provided with graduated slots, one strip on one side of the slotted space being dentated and the other strip on the other. A screw, fitted with a cog sufficiently deep to engage both, is now placed in the centre, so that by simply turning the screw the bridge is either lengthened or shortened (see

Fig. 4). The writer modified this by introducing a dove-tailed connection between the two strips, which allows them to slide easily upon each other and yet prevents displacement (see Fig. 5). From pages 20 and 21, the ensuing paragraphs, which entirely cover the applications of the principle Dr. Wyeth claims as original, are copied verbatim. There is a difference in the form of ratchet used for extension, but the principle for which we both contend is the same, although my paper passed into the critic's hands one year before his.

"Second condition.—When the lower dorsal and lumbar vertebrae are involved.

"Requirements.—1st, exposure; 2d, immobility; 3d, facilities for extension or retraction; 4th, relief from the weight of the parts above.

These are met by the employment of plaster-of-paris bandage and either of two brackets devised by the writer.

"The first is composed of two zinc plates, perforated, firmly riveted to and connected by a strong strip of vulcanite, provided with a ratchet, and raised above the surface in the centre (see Figs. 6 and 7).

"The second is like the first, except that two ratcheted strips are provided instead of one, and possesses the advantage over it of increased strength and the avoidance of the vertebral projection (see Fig. 8).

"1st. Impossibility of ascertaining the progress of the disease until the splint is removed.

"2d. Impossibility of graduating the local pressure.

"3d. The patient's form is obliged to remain in the position it assumed during the application of the plaster until the splint is removed.

"The various braces, on the contrary, do not produce sufficient immobility without causing severe and unequal pressure upon some of the most prominent points of the trunk, but they possess the advantages of being *more easily regulated* and of allowing *inspection of the diseased region*.

"By using the plaster-of-paris bandage, and the brackets originated by the writer, we are enabled to combine the advantages of the two, viz.:

"1st. Immobility.

"2d. Exposure.

"3d. Facilities for extension or retraction, and yet avoid the disadvantages of each used singly."

These illustrations show the brackets as applied to the plaster base before being secured in position by the plaster bandage, or covered by the external layer of bleached muslin.

In conclusion, let me state that I am personally acquainted with Dr. Wyeth, and know him to be a gentleman of rare acquirements and scholarship, and feel perfectly assured, had he known the true state of the case, that he would have fully accorded me the priority I claim.

Very truly,

CHAS. F. STILLMAN, M.D.,

Curator St. Francis' Hospital, N. Y.

PLAINFIELD, N. J., Feb. 12, 1879.

FREE PHOSPHORUS INVARIABLY AND NECESSARILY CHANGED TO HYPOPHOSPHITE BEFORE ABSORPTION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—It is claimed that the chemical changes occurring to substances after entering the body cannot be followed out intelligently owing to the complication caused by the modifying influences of vital and functional action, the presence of a multitude of substances, and the changed scene of action as compared to the laboratory, rendering it impossible to note changes as they occur, all of which, as a rule, with some exceptions, is doubtless true.

One exception to this rule I believe to be the changes undergone by free phosphorus from the time of its introduction into the stomach until by absorption it leaves it. My reasons for thus excepting phosphorus during the period mentioned are:

That it is an element incapable, primarily, of chemical action, except in certain well-known directions, which change is a necessity with it as a preliminary step to further combinations.

The first change that occurs must be that it unites with something else, because, being an element, it is itself ultimate—that is, cannot be subdivided into two or more substances; it therefore exerts single elective affinity—its strongest affinity is for oxygen.

FIG. 7.

FIG. 6.

FIG. 8.

"If the deformity is great, it will be necessary to suspend the patient during the application of the plaster, which is laid around the chest above the site of the disease and around the pelvis below it.

"When it has set, the bracket is applied, secured with fresh turns of the plastered bandage, and finally the whole surface is neatly covered with bleached muslin rollers, and the degree of extension adjusted by the ratchets.

"The practice of encasing the waist in plaster from the hips to the axillae (well known as Sayre's method) is superior to most of the braces in use on account of its *immobility* and the *ease* with which it is carried by the patient, even for a prolonged time, the weight being so well distributed.

"Its chief disadvantages are:

Having proceeded thus far, I will state my reasons for the conclusion heading this paper.

Solutions of phosphorus are precipitated in the stomach previous to assimilation.

Water precipitates phosphorus from its solutions when it mixes with its solvent.

Therefore phosphorus must be precipitated from its alcoholic solution by the aqueous character of the stomach secretions.

Phosphorus dissolved in ether, if given in this form, is left by the evaporation of the solvent; and the oleaginous solution, having undergone pancreatic emulsification, is chemically changed by that process to a condition which admits of union with aqueous secretions in any proportion, and as emulsification must have taken place before fats can be absorbed, the phosphorus, but sparingly soluble originally in the oil, must be precipitated when the oil is not only emulsified, but combined with aqueous secretions at the time of assimilation; hence phosphorus, even if given in solution, reaches the condition of substance in the stomach before absorption can take place.

Phosphorus being insoluble in stomach juices is incapable of endosmosis until by chemical change it is rendered soluble.

Its natural and strongest affinity being for oxygen, an atom of phosphorus (P) unites with an atom of oxygen (O), two molecules of water from the stomach secretions (2HO) now unite with it, and the result is 2HO, PO (hypophosphorous acid); and as the free acid cannot exist in the presence of bases without union, and as such bases are always present in the stomach, this union occurs naturally, and a hypophosphite is produced, affording the first soluble condition of the phosphorus originally given—necessarily in very small proportion, from the limited quantity of phosphorus ($\frac{1}{100}$ to $\frac{1}{50}$ grain) tolerated by the patient.

During the oxydation of the phosphorus in the stomach, phosphoretted hydrogen is given off (a result always occurring during the primary oxydation of phosphorus), and this having an avidity for water, is taken up by stomach juices, and being then in a condition favorable to such action, is absorbed.

This accounts for the constitutional toxic action of phosphorus, evidenced by hematomata upon the heart, pleura, liver, kidneys, etc.—for the odor of phosphorus pervading the body of a person poisoned by phosphorus, and also for the peculiar "match-like" eruptions complained of by patients when taking free phosphorus.

I am very respectfully,
R. W. GARDNER.

170 WILLIAM STREET, N. Y., Jan. 16, 1879.

PHILADELPHIA APPOINTMENTS.—Dr. W. W. Van Valzah, late resident at the Philadelphia Hospital, has recently been appointed one of the Attending Physicians to Jefferson Medical College Hospital in the place of Dr. John B. Roberts, who resigned to take charge of the Philadelphia School of Anatomy.

Dr. Charles Baum was appointed house interne at the Pennsylvania Hospital, at the last meeting of the Board of Managers, to fill the place of Dr. Henry Middleton Fisher, whose term of service had expired.

At the meeting of the Board of Managers of the Philadelphia Asylum for the Deaf and Dumb, on Wednesday evening, Feb. 5th, Dr. J. Minis Hays, a member of the board, and assistant editor of the *American Journal of the Medical Sciences*, was elected to fill the position of Attending Physician, formerly held by the late John B. Biddle, M.D. The other candidates for the position were Dr. Samuel Ashhurst, formerly attending surgeon to the Episcopal Hospital; Dr. Wm. B. Atkinson, Permanent Secretary of the American Medical Association; and Dr. Oscar Allis, Attending Surgeon to the Presbyterian Hospital. The salary in connection with the position is some \$600.

At the meeting of the Household Board of Directors of Girard College, held on Friday evening, Feb. 9th, the name of Dr. Thomas B. Reed, Attending Physician to the Presbyterian Hospital, was recommended as successor to the late Dr. J. B. Biddle, as Attending Physician to Girard College. The candidate recommended by the above board is generally elected to the position by the Board of Guardians of the City Trusts, which meets on Feb. 12th. The salary of the Attending Physician is \$600. The other prominent candidates were Dr. Wm. H. Parish, Attending Obstetrician to the Philadelphia Hospital; and John J. Reese, M.D., Professor of Medical Jurisprudence and Toxicology in the Department of Law and Medicine in the University of Pennsylvania.

The last candidate who has announced himself in connection with the vacant chair of Materia Medica and Therapeutics at Jefferson Medical College, is Dr. James Darrach, of Germantown. The appointment will not be made until late in the spring.

DR. H. T. HANKS, of this city, has been elected Corresponding Member of the Gynecological Society of Boston.

SALICYLIC ACID A BAD MOUTH-WASH.—Dr. Buch, of St. Petersburg, finds that even a weak solution of salicylic acid is injurious to the teeth, which, after the dentifrice has been used for a short time, appear softer, and feel as though they were covered by something gritty.

SUICIDE OF A YELLOW FEVER PHYSICIAN.—Dr. George Grey, of Denison, Texas, who distinguished himself by professional services rendered at Holly Springs during the late epidemic, committed suicide at New Orleans on Feb. 15th, by shooting himself through the head. No reason for the act is assigned.

BACTERIA IN CARBUNCLE.—W. T. Jackman, M.R.C.S. Eng., reports (*Lancet*) two cases of carbuncle in which he found bacteria in blood drawn from each patient.

DR. LUIGI CINISELLI died last month, aged seventy-five years. He was many years chief surgeon of the hospital at Cremona, Italy. He gave great attention to and was an able advocate of the electrolytic treatment of aneurism. He was the author of many papers on this and other subjects bearing upon surgical practice.

LALLEMAND'S GOUT SPECIFIC is said to be prepared at St. Louis, Mo., after the following formula:

R. Ext. colchici acet.,	
Ext. opii aquos \bar{a} .	gr. xv.

HARVEY AND HIS DISCOVERY.—We have derived much pleasure in the perusal of the address made by Prof. DaCosta at the opening of the present session of Jefferson Medical College.

DIALYZED IRON IN ARSENIC-POISONING.—Edward Hirschsohn, of Dorpat, has experimentally proven that pure dialyzed iron alone does not act as an antidote to arsenious acid. The addition of ammonia or magnesia to the iron causes the production of an insoluble compound of arsenic, iron, and magnesia or ammonia.

QUINIA INSUFFLATIONS IN PERTUSSIS.—Dr. Mannheim claims to have cured nine cases of pertussis in from four to seven days by the use of intra-laryngeal insufflations of equal parts of *quinia sulph.* and *creta præp.*

A NEW MEANS OF ARRESTING POST-PARTUM HÆMORRHAGE.—Dr. Christie, in *Med. Press and Circular*, Sept. 4, 1877, describes a new device as follows: An india-rubber pint bag with a tube and stop-cock attached. The air is squeezed out of the bag, the cock turned, and the former is to be introduced within the cavity of the uterus. The end of the tube is then to be placed in a vessel holding tepid water, which is held two feet or more above the uterus. The cock being again turned, the bag becomes filled by atmospheric pressure, thereby overcoming the uterine intra-arterial pressure. Leaving the valve (regulated by the cock) open, as the uterus contracts the water is expelled from the bag; if the womb again relax, the bag is again enlarged by the water-pressure. Smear the outside of the bag with glycerine. For placenta prævia use cold instead of tepid water.

TEST FOR ORGANIC MATTER IN WATER.—Put some of the water into a clean glass-stoppered bottle; add a little pure cane-sugar; expose, having well stoppered

the bottle, to the light in a warm room. Should the water, even after a week's exposure, become turbid, it is dangerously impure for drinking; if it remain clear, it is safe. This is Heinsch's sugar-test.

SULPHUROUS ACID IN SCARLATINA.—Is highly extolled by Dr. Waterman. He gave 10 to 30 drops, diluted, every 2, 3, or 4 hours, to eleven cases, ten of which recovered.

CHLORAL ANÆSTHESIA IN CHILDREN.—Dr. Boucbut says that a dose of grs. 35 to grs. 45, for children under three years of age, is without danger, produces sleep in half an hour and profound insensibility in one hour. This anæsthesia lasts from three to six hours, without any unpleasant consequences. This is the opinion from nine years' large experience.

SAYS Prof. Alonzo Clark: "As a matter of fact, two-thirds of patients sick with typhoid fever do better without than with alcoholic stimulation."

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.—The Thirty-eighth Annual Commencement of the Medical Department of the University of the City of New York was held in the Academy of Music, Tuesday evening, February 18, 1879. The Academy was filled to overflowing with the friends of the students and the invited guests. The music was furnished by Grafulla. The exercises were opened by the reading of the Scriptures by Chancellor Crosby, and prayer by Rev. Dr. Deems. Chancellor Crosby then conferred the degree of Doctor in Medicine upon the two hundred and five members of the graduating class, after which he delivered the address to the graduating class. As usual, the Chancellor's remarks were plain and solid, and contained the following jewels:

1. "A rolling stone gathers no moss," or, "An itinerant doctor gets no practice." A restless fisherman didn't get bites, but went home at evening with an empty basket.
2. "The early bird catches the worms." If the doctor was ready on call, the people would be ready with their calls.
3. "Pleasant words are health to the bones," which might be read: "A doctor's cheerfulness is often as good as his physic."
4. "Take care of the pennies and the pounds will take care of themselves."
5. "Industry wins the prize."
6. "Nip mischief in the bud." The address was closed by giving the graduates a few general sentiments, such as: "Yours is a profession, and not a trade. The object of a trade is to make money; the object of a profession is to bless mankind."

The Mott Prize Medals were awarded as follows: For the best dried anatomical preparation, gold medal, to W. R. Winters; for the second best, silver medal, to Gregory Iskiyan. To E. R. Boden was awarded a bronze medal for the best report of a surgical clinic. For the best examination in Pathology and Practical Medicine, the prize was awarded to J. C. McCoy. For the best examination in Materia Medica and Therapeutics, the prize was awarded to E. E. Wallace. For the best examination in Ophthalmology and Otolaryngology, the prize was awarded to William T. Smith. To W. J. Herriman was awarded the prize for the best examination in Obstetrics, and to W. Edwin Walker for the best examination on Diseases of the Nervous System. Honorable mention was made of the examinations sustained by C. M. Glenn, C. H. Brown, D. H. Wiesner, E. K. Root, C. Herzog, W. W. R. Fischer, N. H. Wilber, W. O. Bridges, G. W. Leonard, W. C. Davies, G. Voorhees, C. E. Grovesteen, H. M. Brown, F. H. Miller, and W. L. Ranney. The theses presented by M. W. Van Denburg and C. M. Brandt received honorable mention.

Original Lectures.

YELLOW FEVER—ITS ORIGIN, PROPAGATION, NATURE, AND MORBID ANATOMY.

A LECTURE DELIVERED BY SPECIAL REQUEST BEFORE THE GRADUATING CLASS OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA.

By ALFRED STILLÉ, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE.

PART I.

GENTLEMEN:—It is not my intention to present to you in this lecture an elaborate history of yellow fever, a work for which neither my time nor my ability would suffice. The few cases of the disease that I have myself seen give me no authority to speak of it from experience. But there are certain questions relating to its origin, propagation, and nature, which an impartial critic may perhaps decide more justly than physicians who have only their personal experience to enlighten them. It is notorious that some reporters of their own observations—not only in our own day, but even in former times—have obscured the subject by confounding together yellow fever and various forms of bilious remittent fever, and notably the malignant and the hæmaturic varieties of this disease.

THE FIRST MENTION OF YELLOW FEVER.

It is unquestionable that the earliest account of yellow fever is contained in the histories of the Spanish discoveries and colonization in the West Indies. From them we learn that an epidemic of the disease decimated the Spaniards on their second expedition to St. Domingo, at the end of the fifteenth century. During the following century it was elaborately described by the physicians who witnessed its ravages in the French colonies of Guadaloupe, St. Christopher's, and others.

From these original centres it was soon carried to Mexico and the other parts of the shores of the gulf of that name, where it certainly prevailed toward the end of the seventeenth century, and various points in North America during the following century. In all these latter places, that is, upon the American continent, there is no reason to believe that yellow fever was ever seen until it was brought thither from the West Indies. In like manner it is certain that, until commerce carried it to the eastern and western coasts of South America, it was never known in any of the localities which since then it has ravaged, and in some of which it appears to have become endemic, as it certainly has at several places on the southern coast of the gulf of Mexico; but not in all: for example, it was introduced into Dutch Guiana in 1793 and in 1800, and yet subsequently, and for a period of thirty-seven years, it never invaded that province. At the end of this long period of immunity the colony suffered from a new importation of the disease, which annually thereafter visited it for nine or ten successive years, when it ceased, and for the six following years failed to occur. It was then reintroduced by an infected vessel, and spread more widely than before. In Brazil, likewise, yellow fever never occurred until it was brought in 1849 by vessels from New Orleans and the West Indies, which infected all the ports at which they

touched. From thence the disease travelled inland, causing an immense mortality. On the western coast of South America yellow fever was equally unknown until 1842, when it was introduced by vessels from New Orleans; but it soon afterward became extinct, until ten years later, when it was brought to Lima, in Peru, whence it extended to Valparaiso and other ports of Chili. All of these instances of the spread of yellow fever from the Gulf of Mexico to the coast towns of South America are distinctly traceable to the gold discoveries in California, which drew thousands of emigrants from the States east of the Mississippi, most of whom were passengers on board vessels that either sailed from New Orleans, or which tarried at some one or more of the yellow fever centres of the Gulf of Mexico.

THE SEEDS OF TRANSATLANTIC EPIDEMICS IMPORTED FROM AMERICA.

The history of transatlantic epidemics of yellow fever shows that their seeds were imported from America. It was so at Cadiz as early as 1731. But the great epidemic which desolated that city and the surrounding provinces from 1800 to 1804 was still more distinctly traceable to an infected ship from Charleston. Subsequent epidemics in Spain, several of which occurred down to 1828, were as clearly due to importation. It is worthy of notice that the only portion of Europe which was thus subjected to the plague was the one of all others whose commercial relations with the West Indies were the most intimate and frequent. Not only Spain, but other places in Europe where yellow fever has prevailed, furnish similar illustrations, and among them Lisbon, where for more than a century it from time to time occurred extensively and fatally, but always as a consequence of the commerce maintained between that port and the American endemic sources of the disease. On the western coast of Africa it has again and again occurred at several points, and there alone, the remainder of that continent never having known the disease. This fact is evidently and simply to be explained by the constant intercourse of the people of the west coast with the West Indies in the interests of the slave-trade.

In North America yellow fever has occurred at such places only as were in communication with one or another of its foci in the West Indies. In Baltimore, Philadelphia, New York, Boston, and other northern ports, the limited epidemics that have occasionally occurred have all, without a single exception, been traceable to vessels or their cargoes arriving from infected ports. Even these rare and limited outbreaks of the disease have grown less frequent and less extensive in proportion to the strictness with which quarantine laws and sanitary regulations have been observed. To such a degree of efficiency have these barriers reached at the port of New York, that, although for years past there has been no time during the prevalence of yellow fever in the West Indies when there have not been cases, and sometimes many cases of it, in the quarantine hospital at Staten Island and in the infected ships at that station, there is no instance of the disease having been carried to the city by any vessels, persons, or goods that had passed quarantine.

YELLOW FEVER DOES NOT ORIGINATE OUTSIDE OF THE WEST INDIES.

In a word, not a single example can be adduced to prove the origin of yellow fever outside of the West Indies. On rare occasions it has been observed at

some of the minor ports of New England, and also in Great Britain and other parts of Northern Europe; but in every such case it was easy to designate the very vessel that brought it from the West Indies; and, although less easy to demonstrate, it is none the less certain that to a like source may be traced all of the epidemics that have ravaged our southern States and those of the South American continent. That for some of them a claim of spontaneous or idiopathic origin has been made, is well known. But, taking together the facts which prove: 1. The ordinary source of yellow fever in importation from the West Indies; 2. the fact that in no single instance can the possibility of such importation be successfully controverted; and 3. the frequent errors of diagnosis committed by physicians who have mistaken various forms of malarial fever for yellow fever—the doctrine of the primary and exclusive origin of the disease in the West Indies receives a full and complete confirmation.

THE CONDITIONS WHICH GENERATE THE DISEASE.

What, now, are the peculiar conditions which generate yellow fever in the West Indies? Long continued heat is certainly one of them, but it is not the sole nor a sufficient cause; for a higher temperature prevails in Africa and Asia, where yellow fever never existed. Neither is moisture, nor animal nor vegetable decay, nor any combination whatever of natural causes, for they all exist as abundantly elsewhere as in the West Indies, without ever generating the disease. Salt water is also essential to its production; for this fever never originates in inland localities, no matter what conditions in regard to heat, moisture, or putrefaction may coincide. These agents may generate malarial fever, but yellow fever never. In not a few instances a vessel sailing from an infected port in the West Indies has proceeded on its voyage for many days, even for several weeks, without accident, until, on opening the hatches or pumping the bilge-water from below the hold, the fever has immediately broken out. In many other cases such a vessel has sailed, it may be, from Havana to one of our own northern ports, or perhaps to Europe; she may have had some cases of the fever on board during the voyage, or, on the other hand, her crew may have remained perfectly healthy. She arrives at a healthy port in hot weather. Her crew disperse, and no one in contact with them contracts the disease. But the vessel's hatches are opened, stevedores belonging to the port unload its cargo, and presently they are all attacked with the fever, as well as the men on board the vessels lying alongside of the infected ship. It is evident that the ship itself, or something in it, but not its crew, was the cause of the outbreak, and equally evident that the morbid poison must have been brought from the port whence the ship came. It is just as certainly generated outside of the human system as that the cause of malarial fever is so, from which, however, it differs essentially in this, that it is portable in a great variety of things, including ships, merchandise, and clothing. When once introduced into a place it does not, like an aerial poison, spread rapidly and attack the population in every direction, as malaria does, but it is first developed around the spot where it first entered, and attacks those only who visit that locality, or who come into contact with fomites which have for some time remained in it. There can be no doubt, in view of the facts already stated, and of numberless corroborative ones, that the poison of yellow fever is specific; that its origin is in the islands of the Gulf of Mexico alone; that it is susceptible of being carried to distant points; and that it is as distinct from all other

fever-poisons as the plants and the shells of the West Indies are from those of Pennsylvania.

The conclusions I have stated are drawn from a multitude of facts, and of themselves would be sufficient to establish the limited local origin of yellow fever and its dissemination by means of a specific poison. But the counter-proof confirms the argument. Yellow fever neither exists endemically in any other place in the world than in those mentioned, nor has it ever prevailed epidemically in any other place into which it was not introduced from its original source. At the present day we hear no more of such epidemics as, a generation or more ago, ravaged certain ports of Europe. Even sporadic cases of the disease no longer occur in them, and yet, in all respects save one, their sanitary condition is nearly the same as it was when the calamitous invasions of the fever took place. They are more populous, nearly as filthy, their commerce with the West Indies is as intimate, their climatic conditions are unchanged, and yet they are as free from yellow fever epidemics as before America was discovered. The reason of their exemption is simply that they refuse to admit vessels from infected ports until they have been purged of all sources and vehicles of the disease.

THE EFFICACY OF A RIGID QUARANTINE.

The precautions which have proved so salutary abroad have been no less effectual in this country whenever they have been honestly and thoroughly taken; and there is every reason to believe that yellow fever would never again since the civil war have entered our southern ports, if the quarantine laws had been faithfully executed. During the war and for some time afterward yellow fever ceased to appear at New Orleans; and it is certain that the seeds of the recent epidemic were introduced into that city through the neglect, ignorance, or connivance of those who were charged with the duty of protecting the country from this mortal scourge. It is equally well known that as soon as the nature of the epidemic was recognized in New Orleans, another populous seaboard town, peculiarly liable to be infected from New Orleans, resolved upon absolute non-intercourse with the City of the Plague, and maintained its isolation throughout the epidemic. In vain it was threatened with a loss of commercial relations by certain influential corporations and individuals; it preferred life to wealth, and closed its port against the carriers of the pestilence who endeavored by force or stratagem to invade its sanitary line. It was rewarded by the result, for not a single case of yellow fever occurred in that city, while its less wise and prudent sisters in Louisiana, Mississippi, and Tennessee, who received the fugitives from New Orleans, were severely scourged.

The efficacy of duly executed quarantine laws is nowhere more distinctly displayed than by their administration at the port of New York, where, it is stated, more cases of yellow fever arrive between the months of July and October than at all the other ports of the United States. "During this period there is a daily average arrival of one or two infected vessels, and yet at no time for a number of years has the yellow fever made its appearance in that city." "This statement must go side by side with the one that New York, during its summer season, is as much exposed as New Orleans during the corresponding period."

CIRCUMSTANCES INFLUENCING THE DIFFUSION AND MORTALITY OF YELLOW FEVER.

The circumstances or conditions which influence the diffusion, the grade, and the mortality of yellow fever

are peculiar, and differ from those relating to every other disease. It is well known that malarial fevers attack the same individuals year after year—the natives of the locality where they prevail as well as strangers; but yellow fever is apt to spare the natives of places where it is endemic, and very seldom attacks the same person more than once. Even in cities like our southern seaports, where the disease occurs only through importation, one attack is apt to render its subject invulnerable during subsequent epidemics. Still more than this, the natives of warm climates who go to reside in the yellow fever region are not nearly as liable to the graver forms of the disease as are the natives of colder climates; and it has long been noticed that during its epidemics the mortality is extremely great among the latter class of persons, and relatively small among the former. But neither will being a native of such a place nor a long acclimation secure an absolute immunity from the disease. Like typhus and typhoid and eruptive fevers, it is occasionally liable to attack those who have already paid tribute to it. During epidemics of an exceptional degree of violence or malignity such cases are not uncommon. Moreover, the immunity is very apt to be forfeited by natives of yellow fever localities who have resided long enough in a cool climate to undergo a certain change of constitution. On returning to their native places they are hardly less liable than original foreigners to be attacked.

THE COMPARATIVE IMMUNITY OF THE NEGRO RACE.

A remarkable difference of susceptibility to yellow fever exists between the white and colored races. Observers in the West Indies and in our Southern States, before the civil war, are agreed that the latter race are almost entirely exempt from its attacks, and several affirm that no negro from the coast of Africa was ever affected by it. Even among colored persons born in this country the liability has been comparatively small, and the type of the disease much milder than in whites. It is not without interest that the negro race enjoys a similar immunity from periodical fever also, and especially from that grade of it which, from its malignant type, has sometimes been confounded with yellow fever, while they are more liable than the whites to other epidemic diseases, such as typhus, typhoid, and eruptive fevers, and cholera, and suffer a greater mortality from them. It seems probable, therefore, that their immunity to yellow fever is innate and constitutional. But as it is well known that negroes bred in the northern portion of the Southern States are more liable to the disease, and especially to its graver forms, than those who have always lived in the seaboard towns, it seems probable that mere diversity of race, apart from climatic peculiarities, is insufficient to account for the relative insusceptibility of the southern negro to this disease. When we associate these facts with the one before mentioned, that foreigners are apt to contract the disease in proportion as they belong to cooler climates than that of the West Indies, we are led to suspect that the immunity of negroes is in some manner related to the great functional activity of their skin, which is proper to all natives of the torrid zone, but in the highest degree to the dark races, and which enables them to exhale the specific poisons of malarial and yellow fevers, while natives of cooler climates, being but feebly provided with such an eliminative faculty, fall victims to these diseases.

Such, in the briefest terms, is a history of the conditions under which yellow fever arises, but they shed no light upon the nature of its essential cause. So far

as we know there is not any single climatic, meteorological, or telluric agency which is known to be peculiar to the cradle of the disease, nor any degree or combination of such visible agencies as are met with in the West Indies, that are not even more rife in thousands of places in Africa and Asia, which yellow fever never visited. In default of any demonstrable and real cause, the usual refuge of ignorance has been eagerly sought for by theorists who are not content to seem ignorant of anything. They attempt to blind themselves and us with a cloud of words which describe or define nothing, and which, when reduced to their simplest expression, read "Zymotic Poison." Upon calm reflection this phrase turns out to be little else than "words without knowledge." At the best it can only mean that a certain specific poison must be received into the system to produce yellow fever, as a certain other morbid poison must be absorbed to generate typhus, another, small-pox, and so on, a proposition which no well-informed physician can deny, but which leaves us as ignorant as ever of the specific cause of yellow fever. They neither tell us what it is, whence it proceeds, how it acts, nor where in it differs from other morbid poisons; in fact, leave us quite as ignorant as when they undertook to instruct us.

THE GERM-ORIGIN THEORY NOT PROVEN.

A search after the organic germs which the zymotic theory calls for has been diligently made, but until recently no plausible claim to their discovery has been advanced. Since the late epidemic this has been done by Prof. J. G. Richardson, of this University, and Dr. Robert White, of the United States Marine Hospital Service. After examining specimens from yellow fever patients, dying in Louisville, Memphis, Mobile, and New Orleans, they believe they have discovered that the uriniferous tubules of the kidneys are often choked with a fungous growth, which *mechanically obstructs* the outflow of the renal secretion, and thus causes the diminution or complete suppression of urine, which constitutes such a common and fatal symptom of the disease. They also think that similar groups of fungoid spores (micrococci) frequently form in the hepatic ducts, and, by interfering with the free secretion of bile, give rise to the yellowness of the skin from which the name of yellow fever is derived. They report that the fresh blood of yellow fever patients, sealed up in tubes, and fastened to microscopic slides, so as to be readily examined with a power of 800 diameters, shows a fungous growth, differing somewhat from that developed under similar conditions in normal blood, but consider that their experiments are too few in number as yet to form the basis of any positive statement in regard to the presence of *spores* or *germs* in the circulating fluid of persons affected with this disease.

(To be continued.)

TWO CASES OF HYSTERICAL LARYNGISMUS CURED BY HYDROTHERAPEUTICS.—In the cases of two young girls, who, in addition to the other symptoms of hysteria, suffered from cesophagismus seu dysphagia spastica, Dr. Sieffermann employed all the usual remedies, including electricity, without success. He finally had recourse to the daily use of the douche, in connection with which the patients were directed to make forcible efforts to swallow. In one of the cases the spasm disappeared during the second douche, and in the other during the twelfth. The cure in both was permanent.—*Memorabilien*.

Original Communications.

ON THE USE OF JABORANDI, OR PILOCARPINE, IN THE TREATMENT OF PUERPERAL ALBUMINURIA AND CONVULSIONS.

READ BEFORE THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, FEBRUARY 5, 1879.

By FORDYCE BARKER, M.D., LL.D.

THE remarkable effects produced on the system by the administration of jaborandi, or its alkaloid, pilocarpine—effects never before secured by the use of any agent known in our materia medica—naturally suggested the theory that it would prove of service in relieving the œdema and eliminating urea in albuminuria.

Experiments and clinical observations have now settled the fact beyond all question, that this agent, when administered in sufficient doses, may be relied upon to excite excessive salivation and profuse diaphoresis, and thus drain off from the system by transudation a large amount of the water of the blood. It therefore seemed especially adapted for the removal of œdema. Then it was assumed that by this transudation, urea, in large quantities, would be eliminated from the system, and thus the danger from the retention of this element in the blood would be averted. The action of this medicine in producing this transudation seems to be nearly constant and uniform, and there is a great satisfaction to the medical attendant in the confidence that he is sure of the result that he aims to secure by the use of any given agent. If this agent produces just the effects which, on theoretical grounds, he desired to accomplish, he may be tempted to rest satisfied with this action, without stopping to ask himself whether any benefit really accrues to the patient from its use.

Having had the opportunity, within the past two years, to observe clinically the effect of this agent in several cases of puerperal albuminuria, I have been led to study more carefully the action of jaborandi on the system in this class of cases. I now venture to bring before the profession the conclusions which I have formed, and ask that they may be tested by other observers. Thus we may eventually be able to determine whether it will be of service in such cases, and, what is still more important, whether it can be used with safety.

I will briefly mention the effect produced on the system by jaborandi or its alkaloid, pilocarpine, that already seems to be demonstrated beyond doubt, and then allude to some points in which writers differ in regard to the results.

If the patient be in bed, and well-covered with warm clothing, in about ten minutes after the jaborandi is taken, or in from three to five minutes after the pilocarpine has been hypodermically injected, the face, ears, and neck become deeply flushed, and soon drops of perspiration break out over the body, while at the same time the mouth waters. In a short time the perspiration rapidly increases, the sweat running down the body and soaking the clothes, while the salivation becomes profuse, oozing from the mouth, sometimes in an almost continuous stream. The sweating and salivation persist from two to four or five hours. Sometimes, if the external conditions be not favorable, the above results may be much de-

layed and not appear for an hour or longer, and then perhaps are brought on by brisk exercise. The quantity of saliva discharged is very great, generally from a pint to a pint and a half. There is also, in many cases, a large secretion of nasal and bronchial mucus. The pulse is always quickened, often from forty to fifty beats in a minute, and this accelerated rate continues about four hours, while at the same time the pulse is weaker. There is a depression of temperature ranging from 0.4° Fahr., to 1.4°, averaging about 0.9°. The face, which is at first flushed, becomes pallid while the sweating is active, showing that this sweating is not due to the excess of blood sent to the skin. It often produces frontal headache, sometimes with giddiness and dulness, and the sight becomes hazy, without any alteration in the size of the pupils. In many cases it causes severe pain over the pubes, with a distressing, irresistible desire to pass water, the pain at once subsiding on emptying the bladder, even if it do not contain more than one or two ounces. The jaborandi or pilocarpine does not increase the renal secretion. Chilliness is experienced after the cessation of the sweating stage, and languor and debility usually persist for some hours.

This description of the effects of this agent, chiefly borrowed from Ringer, is in accord with that of all who have reported their experiments and observations. But in some other details there is a notable difference. Bartholow states that there is an immense increase of elimination of urea by the skin, as one of the results of the administration of this remedy; but he gives no authority for the assertion, and as I have been unable to find any experiments reported, which demonstrate this to be the fact, I think we have no right to assume it to be true. In the investigations of Piliere, Stumpf, Craig, and Schwan, no urea is mentioned as having been found in the saliva or sweat. In the July number of the *American Journal of the Medical Sciences* is an article by Professor Tyson, of the University of Pennsylvania, and Dr. Bruen, Physician to the Philadelphia Hospital, in which experiments are detailed showing the effects of jaborandi in eliminating urea by the kidneys in three healthy persons, and in three cases of chronic Bright's disease. It is stated that in health the quantity of urine was slightly increased in the twenty-four hours in one case, and somewhat diminished in two cases, while the urea itself was decidedly increased in each case. In Bright's disease the urine was increased in one case, and diminished in two, while the urea was increased in two instances, and very slightly diminished in one. While these writers regard the jaborandi as useful in Bright's disease, they remark "that this increase of urea is hardly sufficient to justify us in attributing the entire benefit which follows jaborandi sweats in Bright's disease." They believe this advantage is largely due to the removal of fluid and elimination of urea by the skin.

I think with Bartholow that the action of jaborandi is paralyzant of the vaso-motor nervous system. The flushing of the skin and the increased action of the heart is doubtless due to dilatation of the arterioles. The sphygmograph demonstrates the lowering of the vascular tension.

The question we now have to consider is whether the effects just described are likely to be of service in the treatment of puerperal albuminuria, and will aid in preventing or curing puerperal convulsions. Three cases have been reported in which the patients have been apparently benefited, but in none of these is the evidence conclusive. From a study of the re-

ports of some other cases it has seemed to me evident that the action of the jaborandi was injurious and contributed to bring on a fatal result. A brief abstract of six cases of puerperal albuminuria which I saw in consultation with others, will serve to illustrate the action of the agent in this affection, and will perhaps aid us in deciding this question.

CASE I.—March 5, 1877, I saw in consultation with two other physicians, Mrs. M., aged 43, then in the eighth month of her seventh pregnancy. A month previous to this visit she began to have some œdema of the face and lower extremities, which had been rapidly increasing, and at this time the œdema was so excessive that the whole areolar tissue seemed to be infiltrated. The legs, the labia, and the face were enormously swollen, pitting deeply on pressure. She complained of weakness, and was obliged to keep her bed; but she had no other symptom, such as headache, nausea, or impairment of vision. The urine was normal as to quantity, sp. gr. 1020, with no albumen or casts. She had been taking saline laxatives and diuretics, which had no effect in increasing the amount of urine or in diminishing the œdema. I suggested that half a drachm of the fluid extract of jaborandi be given three times a day. March 8th, I saw the patient a second time. The medicine had caused profuse perspiration and salivation, and the œdema was very considerably diminished. The patient was dull, sleepy, and complained of headache. Pulse, 112. The action of the jaborandi had prevented her from sleeping much during the two previous nights. The amount of urine was notably diminished, estimated at sixteen ounces for the past twenty-four hours; sp. gr. 1019. The jaborandi was then given but twice a day. March 10: œdema decidedly greater than at the former visit, amount of urine increased in quantity; but now, for the first time, it was highly albuminous; one-fourth in the tube solidified by heat and nitric acid. The patient had no appetite, was nauseated, restless, fretful, and very nervous. The pulse was weak and rapid. She complained bitterly of the salivation and perspiration. No more jaborandi was given, but the aromatic spirits of ammonia and brandy. She also took ʒij. of the compound powder of jalap and five grains of calomel. March 11, 7 A.M.: The powder given yesterday had produced no effect either on the bowels or kidneys, as she had passed no urine for twelve hours. Six ounces were drawn off by the catheter, and fully seventy-five per cent. solidified when tested by heat and nitric acid. One-eighth of a grain of Clutterbuck's elaterium was then prescribed to be taken every half-hour, until it acted freely. March 12: After taking five doses of the elaterium, free catharsis began, and during the afternoon and evening she had eight large water discharges. No urine had passed except with the alvine discharges. By the catheter two ounces were drawn off, of which about twenty-five per cent. solidified. A half-ounce of the infusion of digitalis, with half a drachm of the acetate of potash, was then prescribed to be taken morning and evening, and twenty drops of the tincture of the chloride of iron three times a day. She was confined rigidly to a milk diet.

I saw her for the last time March 17th. At this time the œdema had so entirely disappeared that I could hardly convince myself that she was the same patient whom I had seen before. She was passing daily about forty-two ounces of urine, and the specimen which I saw did not contain more than five per cent. of albumen. She was taking about five pints of milk daily and was in excellent spirits, as she was certain that she had felt the movements of the child

for the first time for more than two weeks. I subsequently learned from her attending physician that on the 2d of April, after a short and easy labor, she gave birth to a living but feeble child, which afterwards thrived well. The œdema and albumen had entirely disappeared four days previous to the parturition, and her convalescence was unattended by a single unpleasant symptom, except atrocious after-pains which continued nearly a week.

CASE II.—The patient was a primipara, aged 19, seven and a half months pregnant. She was supposed to be in perfect health, as she had no symptoms either of nausea, headache, or œdema until her husband was awakened by the movements of the bed and by a strange sound in her breathing. On lighting the gas he was greatly alarmed to find her in convulsions. Her physician was summoned as soon as possible. Twenty grains of calomel were placed on her tongue, she was thoroughly cupped over the kidneys, and then a stimulating enema of turpentine was given. Cold applications were applied to the head, and chloroform was inhaled as soon as it could be procured. After the fifth convulsion the os uteri was found to be dilating, and delivery of a dead child was hastened by turning. She had eight convulsions before the delivery, but never was conscious from the first attack. After the delivery of the placenta there was very considerable hemorrhage, supposed to be about twenty ounces. She remained in a stupor about two hours after delivery, when she became conscious, asked what was the matter, and why a nurse whom she did not know was with her. She slept quietly for about five hours, awaking frequently to ask for water. She then, while asleep, had her ninth convulsion, and three others followed in rapid succession. A prominent obstetrician was then called in consultation, who introduced a catheter and drew off about six ounces of highly albuminous urine. By his advice a quarter of a grain of pilocarpine was then administered hypodermically. This produced its specific effects, and was repeated in six hours. She had no convulsions after the first hypodermic injection of pilocarpine. I saw her thirty hours after delivery. She was then conscious and answered some questions. But her pulse was very feeble and rapid, her respiration was labored, with loud râles, bronchial, tracheal, and nasal; the transudation from the surface was very profuse, and the nurse was incessantly occupied in wiping the saliva from the mouth and the flow from the nasal passage. She died within an hour after I saw her.

CASE III.—This lady, a primipara in the seventh month of pregnancy, began to complain of headache and some impairment of vision, and her physician found some albumen in the urine. She was treated by cathartics and diuretics for about a month, with no improvement in her symptoms, but, on the contrary, the urine became progressively more albuminous and less in quantity. Her physician then decided to make a trial of jaborandi. Up to this time she had never been compelled to lie down from the time she arose in the morning until she retired about ten in the evening. A drachm of the fluid extract of jaborandi was given at three o'clock in the afternoon and at seven the following morning. It produced its most marked effects of diaphoresis and salivation, but these effects had disappeared when I saw her at 2 P.M. of the same day. On entering the room I was struck with her cyanotic appearance and very great difficulty in breathing. The appearance of asphyxia was so striking that I suspected pulmonary thrombosis, and at once placed my ear over the region of the heart before getting a history of the case. I was surprised

to find that the sounds of the heart could only be heard at the distance of an inch to the right of the sternum; and that I could hear no respiration over the whole left chest, and only at the upper half of the right. She was lying upon the left side, and complained of increased difficulty in breathing when I turned her upon her back. On partially raising her in bed the breathing was somewhat easier. Percussion gave a very flat sound over the whole left side and at the lower half of the right. She was perfectly conscious, and in answer to our inquiries she could not recollect that she had passed any water since she went to bed at four the previous afternoon, one hour after taking the first teaspoonful of jaborandi. She objected so strenuously to the use of the catheter that we did not insist upon it, as she was evidently dying.

Did the jaborandi in this case cause an excessive transudation and rapid effusion into the pleural cavity?

CASE IV.—Mrs. B. was delivered of her fourth child after a labor of two hours, with so little pain that she did not ask for chloroform, which she had inhaled in her three former labors. The accoucheur who had attended her before was out of town, and as she considered herself perfectly well, the physician who attended her in her confinement did not see her until labor came on. Four hours after the labor she was reported to have passed water freely. Nine hours after the labor she was awakened from sleep by the falling of the "blower" which the nurse had placed over the fire. She was immediately seized with convulsions, and had three very severe ones before the arrival of her physician. He immediately administered a hypodermic injection of one-third of a grain of morphia. She had no more convulsions, but slept, breathing quietly, for nearly six hours. Her physician then passed the catheter and obtained only about six ounces of urine, which was highly albuminous. More than two-thirds solidified by heat and nitric acid. He then gave a quarter of a grain of pilocarpine hypodermically with the most perfect success in exciting diaphoresis and salivation. After six hours this was repeated. One hour after, her symptoms became so alarming that I was sent for. I never witnessed so painful a scene. She was flooded by the transudation on the surface. The nurse was incessantly soaking cloths with the saliva and discharge from the nasal passages, and at the same time she presented the unmistakable symptoms of pulmonary thrombosis. I was compelled by the piteous requests of her husband and mother to remain with her an hour until her physician arrived, but she died a few moments after I left the house.

CASE V.—This patient had no symptom of albuminuria previous to her eighth labor, which was very tedious and was terminated twenty-six hours after its active commencement by forceps delivery. She lost very little blood after the expulsion of placenta. She passed water freely six hours after. Then she began to suffer extremely from after-pains. A teaspoonful of paregoric was given every two hours, until she had taken three, but this had no effect in relieving the after-pains. She then had an attack of convulsions, and had five in rapid succession, without consciousness in the intervals between them. After about five hours of stupor following the last, she became conscious. The bladder was relieved by the use of the catheter, as she could not pass it voluntarily. She seemed to be doing well for two days, except that the secretion of urine was less than it should be, but two examinations failed to discover albumen. On the third day her physician discovered that it was loaded

with albumen. As she had been taking all of this time active diuretics, and the bowels had been freely moved, he decided to give a drachm of the fluid extract of jaborandi, which acted most efficiently for about five hours. After the perspiration and salivation had ceased she complained of being chilly, and of headache, and she looked so badly that her physician was summoned. I saw her at nine in the evening, ten hours after she had taken the jaborandi. She was then dying, evidently from cerebral oedema and cardiac asthenia.

CASE VI.—A lady thirty-six years of age, married nine months, supposed herself to be about seven months pregnant. While at church she began to suffer from severe headache and nausea, and was much alarmed to find that she saw very indistinctly. She left church, and her husband at once sent for a physician. She had been up to this time very well, except that she had latterly been very constipated. Five grains of blue-mass were ordered, to be followed in four hours by a Seidlitz powder. This produced one very copious fluid evacuation from the bowels, but no improvement in her symptoms. On Monday morning the urine was found deficient in quantity and very dark in color, but it was not tested for albumen. She was ordered to drink freely a sweetened solution of the bitartrate of potash, and to take thirty drops of the sweet spirits of nitre every third hour. She had no appetite, was extremely nervous, and passed a very restless and disturbed night. On the following morning another physician was called in consultation. He examined the urine and found that fully three-quarters in the tube solidified when tested by heat and nitric acid. He advised that a drachm of the fluid extract of jaborandi should be given at once. Two hours after taking it, the salivation and sweating then being very profuse, she had a violent convulsion, during which the tongue was badly bitten.

During the following six hours she had five more convulsions. Labor was induced by the fingers and the use of Barnes' dilators, and delivery was expedited by version and extraction of the child, the patient being anesthetized by sulphuric ether. Two hours after the labor she was sufficiently conscious to swallow when asked to do so, and resisted, with great nervous excitement, the attempt to pass the catheter. Immediately after this she had a seventh convulsion. When I first saw her, five hours after delivery, she was moribund, the inspiration being very short, with loud mucous rales, and the expiration very prolonged. She lived without marked change in these symptoms about four hours.

The question, which must naturally suggest itself to the minds of all, is whether the development of uræmic symptoms and albuminous urine in the first case, the great depression and exhaustion which followed the use of the jaborandi in the second, the serous effusion in the pleural cavity in the third, the pulmonary thrombosis in the fourth, the cerebral oedema and cardiac asthenia in the fifth, the convulsions in the sixth, or finally the fatal terminations in the second, third, fourth, fifth, and sixth cases, were not chiefly due to the effect of the jaborandi on the nervous system and its modifications of the constituents of the blood? Might not all the good effects sought for in the use of the jaborandi been attained by other agents at less expense to the vital powers and less disturbance of the organs of nutrition? Have not many of us seen cases in which the symptoms have been more alarming and dangerous, except those that we may on reasonable grounds attribute to the jaborandi, which have eventually recov-

ered? I beg to give, in striking and suggestive contrast to these cases, the brief abstract of the report of one which occurred in the Colored Hospital, New York, in the service of Dr. S. Whitall, and is published in the Hospital Gazette, December 12, 1878.

CASE VII.—The patient, aged twenty-two, single, primipara, had, on admission to the hospital, headache, dimness of vision, vertigo, œdema of the face and lower extremities, and albumen and casts in the urine. She was treated by gentle purges and a diuretic mixture, the infusion of digitalis and acetate of potash. On the morning of the 31st of August, 1878, she was delivered of twins, one living and one dead. In the afternoon she became comatose; pulse, 120; respiration, 26; temperature, 103° F.; urine, specific gravity, 1008, of which ninety per cent. was albumen. In the morning she had a convulsion. Three drops of croton oil were then given, and the same evening she was bled, eight ounces being taken from the arm. Sept. 1st: Bowels moved freely; breathing, labored; pulse, 150; respiration, 60; temperature, 105.4° F. She was then put in a cold pack until the temperature should fall, and one drachm of brandy was given every hour. Sept. 4th: She had no headache or other uremic manifestations. On the 8th she was convalescent; pulse, 84; respiration, 24; temperature, 99.4° F.; and the report states that mother and child, a few weeks after, were discharged in good condition.

Would the result have been the same if after the convulsion, when she was comatose, with a very rapid pulse and high temperature, secreting urine ninety per cent. of which was albumen, an enema of jaborandi or a hypodermic injection of pilocarpine had been relied upon for the relief of her symptoms instead of the croton oil and venesection?

The limit of time assigned to me will not permit further discussion of the subject, and I will conclude by expressing my conviction that the utility of jaborandi in the treatment of puerperal albuminuria is more than doubtful, and that, after puerperal convulsions, its depressing influence and action, which is continuous and exhausting, prevents sleep and the repose of the nervous system, and thus renders it in these cases an unsafe and dangerous remedy.

SOME CASES OF URETHRAL SURGERY.

By THOMAS R. BROWN, M.D.,*

PROF. CLINICAL AND OPERATIVE SURGERY AND DISEASES OF THE GENITO-URINARY ORGANS, COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE, MD.

(Read before the Surgical Society of Baltimore.)

CERTAIN noteworthy instances have occurred to me in urethral surgery, where unexpected, and, if we regard the text-books as authority, unusual results have followed practice. These have been numerous; and rather than undertake to recite the whole series, it will accomplish the purpose to narrate one or more of each kind as types.

CASE I.—Mr. C., aged 30, single, occupation farmer, was brought to me February 12, 1878, with a history of having contracted gonorrhœa about two years before. This was slow in getting well. Since the true gonorrhœal discharge ceased he has been annoyed by unpleasant sensations along the urethra, chiefly at a point about four inches from the meatus. These were present during micturition especially, but were more or less constant, associated with a slight gleetish discharge. Combined with these was a "movement"

up and down, as he styled it, of the left testicle. This went on day and night with short intervals, and had become so distressing as to depress his spirits and almost completely unfit him for work or for any of the social enjoyments of life. Whilst handling the scrotum this movement could be distinctly seen and felt. By means of the urethrometer a stricture of large calibre was easily made out at the point where the irritation was chiefly complained of—four inches from the meatus. The latter was also small. The easy play of the instrument, without urethral distention, expanded to 40 F. both before and behind the contraction, called for this—40 F.—as the normal calibre. To this size both the meatus and distal stricture were raised with Otis's urethrotome and a 40 F. steel sound was passed easily into the bladder. No anæsthetic was used, and the pain was slight. The patient was kept in bed for a day or two, and, with the exception of the after-passage of the proper sound, and an occasional astringent injection, no other treatment was instituted. Greatly to his comfort, all the disagreeable symptoms were relieved. He called upon me several months after the operation, in fine spirits, stating that the movement was very slight, only now and then, and that he felt as if a great load had been taken from him. He was an altogether different man; and I can safely assert, that it has seldom fallen to my lot to have seen as great happiness produced by any surgical procedure as was the case here.

CASE II.—Mr. C., aged, 18, a resident of the Eastern Shore of Maryland, was introduced to me by my friend Dr. Henry Salzer, of this place. When I saw him he was suffering greatly from retention, which began fifteen hours before, while making a visit to the city.

Some years ago he contracted gonorrhœa, which soon got well. Before that he had had no trouble with his water. Soon after his attack his urine dribbled away from him at times; at other times the stream was small, and was always ejected with pain and considerable effort. His meatus was very narrow. Silver and gum catheters were successively introduced, but could not be passed beyond a close contraction in the membranous urethra. In consequence of his great sufferings instrumentation was not continued long, and supra-pubic aspiration of the bladder was practised, which afforded instant relief. (In another place I have urged the *great superiority* of this mode of practice over that usually accepted as the right one—prolonged attempts to enter the bladder *per viam naturalem*.) The aspiration was practised at 2 P.M. He was put to bed and a dose of morphia given. When visited by me at 7 P.M., his previous distress had returned, with great distention of bladder. Ether, carried to complete relaxation, was given, and a double catheter—after a short delay, clearly due to spasm at the membranous urethra—was passed into the bladder. This was retained from Thursday to Saturday noon, at which time a careful exploration was made with the urethrometer, finding nothing but the contracted meatus above alluded to. The normal calibre was 32 F. To this the meatus was cut, and a steel sound of that size passed into the bladder without detecting the least resistance at any point.

A sharp attack of urethral fever, characterized by rigor, high temperature, at one time reaching 105°, vomiting, anorexia, and decided jaundice, despite the use of quinine and morphia, succeeded the operation. The fever ended in sweat. After its subsidence the 32 F. sound was inserted on alternate days until bleeding

ceased. The patient returned to his home, and from that day to when last heard from, nearly two years after the operation, was perfectly well.

CASE III.—Mr. G., married, age 33, of short, compact physique, looking the very picture of health, was brought to my office by Dr. Samuel Earle, of Centreville, Queen Anne County, with a history of retention some days before. On account of close obstructions at the membranous urethra, his urine could not be drawn off. The retention was finally relieved by fomentations to hypogastrium, morphia internally, and hot hip-baths, fourteen hours after the trouble began. Patient stated that he had had many cases of gonorrhœa, the last one eight years ago; all of these were hard to cure. For the past seven years he had observed his stream of urine getting smaller until, at the time of consulting me, it was discharged in drops or no larger than a thread. A No. 8 A. steel passed with some difficulty through the membranous urethra, where for a time it was held, and, after having entered, was forcibly squeezed. His urethra was sensitive, and did not bear much handling. As is usual with me, before any urethral or other operation, the urine was examined and found to be healthy. Two days after the examination he was placed under ether, and the urethra explored with the urethrometer; its calibre was 30 F. While the instrument was withdrawn a decided resistance was met with just in front of bulb three inches from the meatus, one-half inch from the meatus and at the latter point. The contractions at and near the meatus were close, the others were of large calibre; all were divided so as to admit the easy passage of a 30 F. sound to bladder. In the membranous urethra, where all the trouble was found at the time of the first examination with a No. 8, there was no stricture.

Smart bleeding followed, which was easily controlled. Quinine and morphia were prescribed, patient placed in bed, and ordered a bland diet. The suggested after-passage of sound was neglected partly, and, on re-examination six months after, showed slight recontraction, which was divided. Since the latter occurrence he has continued well, passing a large stream, and without any recurrence of retention. During erection he has a slight curvature.

CASE IV.—Mr. H., married, without offspring; is of a tall, spare figure; age about 36, and in all respects looking the typical dyspeptic; was brought to my office by his family physician, Dr. Salzer, October 12, 1878, 11 A.M., suffering from retention. He had passed the night in great suffering, vainly endeavoring to empty the bladder. A silver catheter, with a long curve, was introduced, and at first completely stopped at membranous urethra. The point of the instrument was gently, but continuously pressed against the resistance, and in a few moments glided into the bladder, permitting the escape of about one quart of urine. I found upon inquiry that for the past eight years he had been a great sufferer, and his appearance fully sustained his assertion. He looked like a man who had suffered much pain. His troubles included an obstinate dyspepsia, impairment of sexual powers, without seminal escape during congress, difficult micturition, with frequent attacks of retention. The urine was loaded with the octahedra crystals of oxalate of lime, a thick, ropy mucus, with an abundance of spheroidal cells and of shreds. There was neither albumen nor casts. When allowed to stand, a very thick precipitate (white) formed, and the secretion soon became offensive. For all of these he had undergone a prolonged course of treatment, general and local: the latter included bladder injec-

tions prompted by a theory of cystitis, no doubt. Besides all these, he had catheterized himself occasionally with a view of preventing a recurrence of the retention, which he dreaded; notwithstanding, he found no relief. He denied ever having had gonorrhœa, but confessed to inordinate masturbation in his youth. He used, either in chewing or smoking, tobacco immoderately. He was subject to cold feet and hands all the time. His appetite was capricious; his bowels were irregular, and sleep more or less disturbed. None of these could be traced to any business complications. Finding his meatus contracted to a mere pin-point, and him disposed to avail himself of any reasonable source of relief, I recommended an operation, postponing further examination of the urethra to that time—this was appointed for four (4) o'clock, five hours after the withdrawal of his urine. When I reached his dwelling at that hour, I found him in great agony, pacing the floor and complaining that his bladder was very much distended.

In passing I may be permitted to note, what may have occurred to other surgeons, the very rapid manner in which a bladder refills after one of these attacks of retention. The viscus, being filled to its utmost capacity, no longer receives any addition; and it would seem, if no vicarious action take place, as if the secretion really welled up behind, waiting to descend as soon as the reservoir was emptied.

Mr. H. was immediately etherized. The urethrometer then showed the normal calibre to be 34 millimetres. A stricture of large calibre was detected at two and a half inches from the meatus; the latter, as just stated, was exceedingly small. Both of these were divided to full size—34 F., and a proper sound introduced into the bladder. The accumulated urine was withdrawn in large quantity through a catheter. In consequence of the element of spasm in this case, contrary to my almost invariable practice, I tied in a soft gum-catheter. The latter was allowed to remain until the next day, when it was found besmeared from beginning to end with thick, ropy mucus, such as he was in the habit of seeing. The after-treatment was in a measure interfered with by his susceptibility to urethral fever, which would follow the introduction of the sound. I have omitted to mention that certain symptoms suggested a search for stone, which was not found. In one instance they were clearly due to an attack of pyelitis, which is quite capable of producing symptoms like those due to a calculus. During my attendance his urine cleared up, no retention occurred, and my patient was immensely improved. This improvement has gone on to this time, and when he called upon me a few evenings since, he announced himself as afraid that it was all "too good to last." His wife assured me that during their married life of two years he had not passed such urine as since the operation, while he affirmed the same for the last eight years.

CASE V.—Jno. C., age 40, single, in good health; occupation, shoemaker; applied at my clinic in September, 1878, for relief of urethral stricture, with dribbling of urine, etc., etc. He gave the history of a case of gonorrhœa eleven years ago, and of malarial fever during his service in the late war. These constituted about all his troubles for many years. The gonorrhœa was succeeded by difficult micturition and a growing diminution in the size of his stream. This was followed by perineal fistula. Eight years ago, while in Philadelphia, he had retention, and while suffering from this went to the hospital and secured the attendance of a well-known surgeon.

He gives an account of the surgeon's unsuccessful

attempt to pass a catheter, failing in which, he performed perineal section, and combined with the major operation division of the fistula. Patient remained in hospital four months, and in about six months his condition was as bad as ever. On October 22, 1878, after stretching the meatus and the first two inches of the urethra, for the purpose of getting the urethrometer in, the latter was passed to the bulb, and the normal calibre found to be 40. The only resistance found was at a point two inches from the meatus. The whole of this space barely admitted the Thompson. The meatus and other strictures were divided to 40 F., and a sound of this size passed into the bladder. Not the least sign of stricture in membranous urethra. After this he underwent the usual after-treatment, and left the hospital perfectly well. (Patient exhibited and examined.)

CASE VI.—Mr. R., of Virginia, age 26, Hebrew; presented with the following history: Gonorrhœa three and a half years ago, which lasted a couple of months. During this time he stated that he had used every kind of medicine, internally and externally, which an assortment of doctors could suggest. A gleet discharge has continued from that time to the date of visiting me (June 2, 1878). His chief complaint was a fistula in the left half of the scrotum, well back towards the perineum, through which a portion of his urine was discharged. It appeared at first some five months previously, without any premonition; his first intimation of anything wrong was the discovery of something wet running down his thighs. At the next passage, while holding the scrotum in his hand, he observed that the urine ran into it. He sought medical advice, and his physician, finding a small opening, cauterized it. This, for some reason or another, as there was not the least trouble in making water, was followed by the use of catheters and sounds, of which the patient owned a great variety, none larger than No. 12 A. After this the fistula seemed to close, but reopened May 25, 1878, in much the same way as before, and again discharged urine. The urethra measured 37 F., and the urethrometer revealed a stricture two and a half inches from the meatus, which measured 25 F. As is the case with the many Hebrews I have met with, his meatus was of the same size as the urethra. The stricture was divided to 37, under chloroform, and a sound measuring 37 F. passed. For two weeks the usual after-treatment was kept up, and the patient permitted to return home. This was all the treatment, and under this the fistula closed. The gleet discharge, which was probably produced in the tract of the fistula, ceased.

CASE VII.—Mr. X. This needs no further comment than that it belongs to a class of cases which it is intended to represent—cases of gleet depending upon stricture of large calibre, which, do what you will, are apt to continue, unless the strictures are divided.

CASE VIII.—Mr. J., æt. 52, married; of large, muscular frame, and, with the exception of urethral trouble, was well. Ten years ago he contracted gonorrhœa; one year ago he commenced to have some pain and difficulty in making water.

About November 1, 1878, he appeared at my clinic with symptoms of stricture, the stream of urine at best being no larger than a "darning-needle," and generally it came away in drops, associated with straining. The urethrometric examination showed normal calibre to be 35 F., and contractions at three different points anterior to bulb. These were divided completely, hoping that the obstruction in the deep urethra would

disappear; but such was not the result. I declined to render further service to him as an out-patient, owing to the seat of posterior strictures, and urged upon him to enter the hospital. He soon after was admitted to the City Hospital of the College of Physicians and Surgeons, and followed a tonic course of treatment. From time to time attempts were made to introduce one or another kind of instrument into bladder, but all failed, owing to an impassable contraction, or rather an inaccessible opening in the membranous urethra, until December 9th. This was accomplished with the small filiform adjustment that screws to Holt's instrument. This was allowed to remain for some hours, when it was removed on account of pain. Its removal allowed a freer flow of urine than he had had for one year. At 1 P.M., December 10th, heart and kidneys having been previously examined and found all right, he was given chloroform, and the urethrotome (Otis's), raised to 35 F., was made to traverse the anterior strictures, to make sure of their complete division. The persistence of stricture in the urethral curve after this, with the patient thoroughly anesthetized, confirmed the previous suspicions of real organic membranous stricture. The same filiform already referred to was screwed to Holt's instrument, but after careful manipulation was withdrawn with the guide doubled. My conviction as to closeness of lowermost stricture, as well as to the serious risks of internal urethrotomy in this part of the urethra, suggested, as the best mode of relief, perineal section, using Gouley's grooved catheter as far as it would go, which was to a point just behind the union of scrotum and perineum. This was cut down upon and withdrawn, preferring to encounter for the rest of the work all the objections of section without a guide, because of false passages. With no more than the usual difficulty, the stricture anterior to prostate was found and divided upon a director. The band was narrow. The common female catheter, the same that I have used on previous similar occasions, was passed along a perfectly smooth channel towards the bladder. It was inserted slowly and carefully, using at the same time a stylet for the purpose of removing clots. The catheter having passed within the lips of the wound and beyond the easy reach of my fingers, much for the sake of giving myself rest from a most fatiguing position, I stepped to the instrument shelf, near the table, to get a pair of dressing-forceps. When I returned, in the course of a minute, I was amazed to find that the catheter could not be seen or touched. Believing it scarcely possible for it to have really entered the bladder, I had the operating-table and floor carefully examined and every instrument collected and counted. The catheter was not to be found. The stone-searcher was introduced, and at once struck the missing instrument, apparently lying crosswise in the bladder.

Forceps of different kinds were used, but could not secure the catheter. Median incision of the prostate was performed with the hope of getting it with my urethral forceps and finger combined. An enlarged prostate made it impossible for me to pass the latter further than the apex of the gland. By this time the patient's condition began to show signs of failure from prolonged anæsthesia—two and a half hours. His expression was bad, pulse small and intermittent, gagging and vomiting constant. It was deemed best to delay further attempts to extract the foreign body, considering that its presence was not likely to inflict as great damage as prolonging the anæsthesia. On account of bleeding, after the perineal crutch was applied—the value of which, as a means of controlling

hemorrhage at this point, can scarcely be exaggerated—and the limbs were tied tightly together, he was put to bed. The nausea with green vomit kept up until midnight, and returned at intervals for several hours afterwards, despite remedies. He slept little during the night, on account of this symptom. There was at no time any vesical tenesmus. The urine passed was ammoniacal, due no doubt to previous condition, as he never, I may say, at any time entirely emptied his bladder within the last year. His pulse the next morning was 120 and temperature 100° F. At 11 A.M., aided by my colleague, Prof. Latimer, a second attempt was made to seize the catheter and withdraw it, after enlarging the prostatic opening, but without success.

Stimulants were given before the chloroform, but the condition of the patient was such as soon to compel a discontinuance of our efforts. There was no difficulty in feeling the instrument, but it could not be engaged. The bladder was unusually spacious. Under all the circumstances, it was concluded to be best to await further developments before having recourse to any of the many methods that might be suggested for such a case. His condition at the time of writing is excellent, there being not a single symptom present to indicate the presence of this body in his bladder. His urine is passed in large quantities through the perineal opening, without the least pain or effort.

An explanation of this curious occurrence is difficult. The sudden disappearance of the catheter surprised me beyond description, and, as stated in the text, it was not until after a careful search for it among the other instruments, and the final finding of it in the bladder, that I was convinced of its whereabouts. I do not think that I could have pushed it away with the stylet, for the reasons apparent. As an aid to the solution, we can recall the violent gagging that went on continually, with its alternate compression and expansion of the whole abdominal wall, including hypogastrium. (I propose to test this theory upon the dead subject.) The nearest that I can come to an explanation is that the catheter, having once entered the urethra fairly, was, by means of a sort of suction movement, aided by collateral muscular action, drawn into the viscus. The further history of the case will be presented when it is completed.*

Summary.—Case I. is a representative of a class of cases in which stricture of large calibre causes constant spasm of a distant muscle with distressing “motion” of testicle, so claimed because the latter was relieved by treatment of the former.

Cases II. and III. represent a very large number, in my experience, of cases in which from the symptoms the *real* disease might be referred to the membranous urethra; but the latter proved to be consecutive and truly spasmodic, depending upon anterior organic contractions, by its entire disappearance after the complete division of the coarctations in front. As stated by me in my address before the Maryland State Faculty, the number of such cases I have met with is so large as to make me very sceptical as to the alleged frequency of membranous strictures. The whole surroundings are so deceptive that much caution is required before any operation is undertaken,

* Since submitting the manuscript, Mr. J. has died. The nausea and vomiting which began on the operating-table did not entirely pass away until just before his death (11 A.M., Dec. 18th); with the exception of one slight attack of retention and an increasingly ammoniacal urine, there were no symptoms pointing to the foreign body in the bladder. His urine was passed in large quantities, and almost invariably without pain. A severe attack of cervical neuralgia, complete anorexia, insomnia, and slough of perineal opening helped the fatal issue. It does not seem that the catheter in the bladder was at all responsible. The prolonged vomiting from the chloroform did the most.

lest, instead of cutting into a genuine stricture, we may be cutting a “spasm.”

Case V. seems to be a case of this kind, in which an eminent surgeon, by overlooking the element of reflex action, judging from all the collated testimony, did perineal section because *there* was the point through which no instrument could be passed, and because, by our very defective methods of examination generally in use for the detection of stricture, he could find no trouble in front.

Case IV. is typical of another class of cases, in which, according to eminent authority, serious disease—local and general—seemingly can be produced by a contracted meatus, and a stricture of large calibre, so claimed for the reason that the patient entirely recovered after their division.

Case VI.—This is where a stricture of large calibre—large enough to permit the flow of a large stream of urine—was able to produce a fistula which would not close until after the strictured point was raised to the size of the rest of the urethra.

Case VII. belongs to a class of cases in my hands not nearly so large as in others, where a gleet has been cured by division of large strictures and contracted meatus.

Case VIII. needs no additional comment besides that contained in the notes.

GELSEMINUM FOR HECTIC.

By EDGAR HOLDEN, M.D.,

NEWARK, N. J.

It is by no means a new or Hahnemannian doctrine that special symptoms may be treated without regard to the essence of the disease; for whatever books may have taught, teachers and pupils alike have been compelled to give heed at the bedside to devices and remedies for the arrest and control of one of the symptoms of consumption, viz., hectic, the harassing chill, the diurnal fever which exhaust the patient and try the courage of the physician.

Fortunately it is not always a prominent symptom, but it is almost always sure to occur sooner or later in the course of the disease, and often so persistently as to destroy entirely the patient's hopefulness and courage.

Pollock says that of 1,200 cases fifty per cent. had hectic on admission to the hospital, and in the cases studied by Louis, a majority had rigors and fever on admission. In twenty per cent. it persisted in spite of remedies from the beginning to the end. In sixty per cent. it began in the second stage, but perspiration followed the fever in only ten per cent. of those who suffered from the chills. His treatment seems to have been simply by the febrifuges then in vogue.

It is somewhat interesting to note the remedies of the past in this matter.

Thus Poterius advocated tin, antimony, and nitrate of potash; Reid, nitre and tartar emetic; Sydenham, infusion of rhubarb in beer; Galen, vinegar and water; Orban (Thompson's *Materia Medica*), the same, with alum and sulphate of iron.

Digitalis, opium, etc., are familiar, and as homœopathic physicians have laid claim to some success in this matter it may be of interest to enumerate their remedies.

Inquiry of several physicians prominent for their adaptation of experience and common sense to their

practice, in spite of dogmas or favorite tenets, has resulted in replies equally courteous and plausible.

Cinchona and its alkaloids predominate. Sulphuric, nitric, and phosphoric acids; iodine, arsenic, and carbonate of lime, with the usual hygienic measures, are resorted to according to the phase of the disease and the condition of the patient.

Not to elaborate this part of the subject it will repay any thoughtful mind to ask the question, What is the immediate cause of the phenomenon? The most prevalent opinion is probably, aggressive, local inflammation. With many, and perhaps the more eminent in the profession, it is ascribed to the absorption and circulation of pyogenic matter. This is the opinion of Ruehle in his recent masterly exposition of the whole subject of phthisis and tuberculosis.

These, however, are not wholly satisfactory even to their advocates; because not fully explaining the phenomena; and after all, would not the statement that irritation is present, and *par excellence* irritation of the ganglionic system, be more adequate and yet in no wise conflict with the opinions expressed?

There is to my mind so clear a relation between the irritative chill of neurasthenia or fright or indigestion, the chill of inflammation, which is of necessity a prodroma of fever, and the chill from septic absorption which also necessitates the idea of fever, that it appears singular that it should ever be overlooked. In all, the element is "irritation," and irritation of a special system of nerves. In the two latter our attention is so soon absorbed by the disease to be counteracted that the first exhibition of the rebellion of the system is forgotten.

Now whether in phthisis the source of immediate irritation is pyogenic absorption, persistent inflammation, profuse exudation of albuminous matter, or the mere presence of the unabsorbed products of slow inflammatory action, or perhaps some peculiar condition accompanying caseous degeneration, the essence of the phenomenon is the same, viz., irritation.

By this and similar process of reasoning I have been led to ask to what extent the remedies thus far advocated have power to reach this, and have been surprised to find that they have analogous action under other circumstances, although here used empirically; and have asked further whether there be not some better and more philosophical deduction in the way of remedy. The answer is the title of this article.

The preparations of gelsemium have been steadily growing in favor for several years, and from an extended experience with them, partly upon theoretical and partly upon inferential grounds, I was led to try them in cases of hectic, which had resisted other well-known remedies until its pre-eminence has become so conclusive as to suggest its recommendation to the profession. Four years ago, in experimenting with it, and testing its action on the heart and pulse with the sphygmograph,* I observed that the number of respirations was reduced before its toxic influence was manifested. Several deaths from over-doses, recorded in the journals, showed an action upon the respiratory centres similar to that of curare or woorara. Practical experience, moreover, with it, in small doses, has long shown its influence upon circulation and its sedative effect in certain neuralgias.

Finally, a writer in the *Lancet* for September of the current year collates the accounts of death from the drug in poisonous doses, and in the summing up shows that sedation and finally paralysis of the respiratory centres has been constantly present.

Now from these facts the inference has appeared a correct one that it should act favorably in the treatment of a respiratory affection characterized by irritation, and having its seat and origin in the pulmonary tissues.

In a very large number of cases it has not failed, and without giving them in detail it will probably suffice to say that I have in prescribing it, even after the failure of favorite and well-known remedies, acquired confidence in it, and have found that in doses of two drops of fluid extr., or 10 to 12 of the tincture every two hours, it will, in most instances, within forty-eight hours arrest the chill, moderate the cough, and allay the fever. The period of administration, however, is not always so short. It may be used continuously if necessary to maintain sedation, and without interference with other medicines or effect upon digestion or the excretions. It should be added that exceptions are likely to occur in cases with mesenteric complication and colliquative diarrhoea, and while not contra-indicated, it may sometimes disappoint expectations.

Reports of Hospitals.

THE EPISCOPAL HOSPITAL, PHILADELPHIA.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Prepared for THE MEDICAL RECORD.)

TYPHOID FEVER.

THERE have been a number of cases of this disease in the wards within the past six months, but treatment has been so successful that but one death has occurred. The patient is maintained upon a soft diet. Dr. William H. Bennett reduces the temperature and strengthens the heart by fifteen-drop doses of the tincture of digitalis, and two grains of quinia, given every three hours. Stimulants are only employed in the severer cases. Dr. Louis Starr controls excessive diarrhoea by injections containing fifteen drops of laudanum and f. ℥ss. of starch. Dilute muriatic acid is given in fifteen-drop doses every three hours, and in the second week of the disease five drops of turpentine are given every three hours. Hemorrhage from the bowels is controlled by the internal use of ergot and the local application of ice (to the abdomen). Dr. J. Anders, the resident physician, in the absence of the attending physician last summer, treated a number of cases in the second week of the disease with one-fourth grain doses of the nitrate of silver, repeated every three hours, with apparently negative results.

ACUTE ARTICULAR RHEUMATISM

Is treated chiefly with alkalies and the iodide of potassium. Salicylic acid has been employed, but the salicylate of soda is considered preferable to it.

COUGH.

Numerous trials have been made in the wards, by Dr. Bennett, of Dr. J. Milner Fothergill's boasted cough mixture, from the use of which he claims such excellent clinical results, viz.:

B. Acid hydrobrom. gtt. xx.
Ex. scilla. gr. ss.
Chloroformi spts. f. ℥ss.

M.

S. Every three hours.

* Prize Essay, p. 160.

with but indifferent results. The experience of the attending physicians has been that it does not at all take the place of morphia, as is claimed by Dr. Fothergill.

PHTHISIS.

Dr. Starr has lately employed the phosphates very generally in the advanced stages of this disease, and with very excellent results, using such preparations as the syrup of the hypophosphites, the vitalized phosphates, etc., etc.

DELIRIUM TREMENS.

A case of this disease has been treated advantageously with twenty-grain doses of the bromide of potassium every two hours, and forty grains of chloral hydrate at bed-time, to be followed six hours later, if necessary, by a twenty-grain dose of the hydrate.

PNEUMONIA.

Quinia is given daily in quantities ranging from 12 to 15 grains in the course of the twenty-four hours. The diet consists principally of milk punch. The circulation is kept up by generous doses of the tincture of digitalis.

THE VOMITING OF PREGNANCY.

A good prescription is, viz.:

℞. Cerii oxalat. gr. $\frac{1}{2}$ - $\frac{1}{4}$
 Ipecacuanhæ gr. i.
 Creasoti gtt. ij.

M.

S. To be taken every hour.

CHOREA.

Dr. Wharton Sinkler has controlled the twitchings of patients with this disease by the continued hypodermic injection of from three to five drops of Fowler's solution. In some of the instances the injections were followed by a good deal of local irritation.

HEMORRHOIDS.

Dr. Starr has injected hypodermically from two to three drops of the fluid extract of ergot in this condition with most excellent effects, always rapidly stopping the hemorrhage.

LOCAL RHEUMATISM AND SCIATICA.

In Dr. Bennett's hands hypodermic injections of one-eighth of a grain of atropia and one-eighth of a grain of morphia directly into the substance of the affected muscle have always afforded immediate relief, although this relief, as a usual thing, is only temporary. In cases of sciatica Dr. Starr has injected the one-eighth of a grain of atropia into the tissues directly over the track of the painful nerve with manifest benefit. Dr. Wharton Sinkler, in several cases of local rheumatism, has tried the local injection of ether—gtt. x. in water. Though this injection generally relieves the pain, yet it is of itself always a most painful operation, owing, no doubt, to the local irritation caused by the ether.

THE ASSIMILATION OF COD-LIVER OIL.

Some months ago Dr. Wm. H. Bennett instituted a series of experiments regarding the assimilation of cod-liver oil by the system. The stools of a number of patients, placed upon the daily use of this article, were carefully examined, and it was found that in the majority of cases these stools were oily, showing that the cod-liver oil had simply passed through the alimentary canal without absorption. Where the stools

were oily, the patients appeared to have derived no benefit from the use of the oil; but in the few cases where the stools were not oily, and where the oil had consequently been absorbed, the patients had grown fat.

Quite recently Dr. D. J. Milton Miller, the medical resident, has conducted a second series of experiments of the same nature, and has obtained like results.

INTERMITTENT FEVER.

Dr. Bennett has lately tried the carbonic acid treatment of the paroxysms, recommended by a surgeon in the British navy, with entirely negative results. This treatment consists in the administration of twenty grains of tartaric acid and thirty grains of the bicarbonate of sodium every half hour for two hours previous to the appearance of the paroxysms.

CHRONIC LEAD-POISONING.

The patient was under Dr. Bennett's care for a long time, with the most marked symptoms of the disease, before any insight could be gained into the cause of the malady. It was at last discovered that the disease first manifested itself when he was cleaning out some leaden sugar moulds. When seen the patient exhibited great debility and a well-marked blue line round the gums, together with the most extraordinary degree of pallor. There was an aortic organic murmur to be distinguished, but, all things considered, the profound anemia seemed to have arisen as a direct consequence of the lead-poisoning. The treatment was by the iodide of potassium and the elixir of iron, quinia, and strychnia.

Dr. Louis Starr treated a case of the same disease lately under his care with ʒij. of the sulphate of magnesium, each morning, and with sulphuric acid lemonade as a constant beverage.

DIGITALIS BY HYPODERMIC INJECTION.

Dr. Starr has recently been employing digitalis hypodermically with much success in cases of advanced phthisis and of heart failure. The injections at first contained gtt. v. of the tincture of digitalis and ℥x. of water. The effects being negative, the amount of the digitalis was increased to gtt. x., with the most decided effects. The pulse fell at once from 120 to 105 in the minute. At one time as much as gtt. xv. of the digitalis were injected with great advantage.

ATROPIA AS A PREVENTIVE OF PYÆMIC CHILLS.

In several instances of abscess of the liver and of pyæmia Dr. Starr administered the one-ninth of a grain of atropia by hypodermic injection and the one-sixtieth of a grain internally to prevent the distressing chills consequent upon these conditions. This remedy acted like a charm. The effects of the dose or hypodermic injection given in the morning lasted through the following twenty-four hours. The same was the case with the belladonna-bath (tr. belladon., f. ʒij.; spts. frumenti, f. ʒij.; aquæ, f. ʒj. S. To be applied to the whole surface of the body by sponge at bedtime).

THE INJECTION OF DIALYZED IRON.

Dr. Bennett injected dialyzed iron hypodermically in several instances recently, and, while the constitutional effects were still negative, was obliged to desist, owing to the severe local irritation produced at the points where the needle entered the tissues. This experience coincides with that of Dr. J. M. Da Costa, at the Pennsylvania Hospital.

Progress of Medical Science.

ASPHYXIA IN THE NEW-BORN.—An interesting case of asphyxia in the new-born is reported by Dr. H. J. Garrigues, in which the child made the first inspiratory gasp *two hours and a half* after delivery. At birth the face was violet, the hands and feet blue, and only a few slow and feeble beats of the heart showed that life was not extinguished. As for the comparative value of the different means employed to induce respiration, the insufflation of air through an elastic catheter was found to give the best results. Of the other means used, the irritation of the mucous membrane of the nose by a feather, and by the vapor of ammonia, and of the skin by the momentary application of ice, had the most marked effect. The object in publishing this case is to emphasize a point upon which most of the text-books are not very explicit, viz., *that if only the heart beats, the life of the child may be saved, even if spontaneous respiration does not appear for hours.*

Cases like this present a great *medico-legal interest*, and instances are cited where the settlement of large estates turned upon the question of the life of the child. The laws of different ages and of different countries prescribe different signs to constitute evidence of life. The slightest trace of vital action, in its common and true physiological acceptation—such as crying, breathing, pulsation, or motion—observed after entire birth and separation from the mother, would be deemed in English law a sufficient proof of the child having come into the world alive. In the present case the child died seven hours after birth.—*Reprinted from the American Journal of Obs.*, October, 1878.

NOTE ON THE STRUCTURE AND MODE OF FORMATION OF THE GIANT CELLS OF TUBERCLE.—MM. Charcot and Gombault have, after careful study and experiments, come to the conclusion that the giant cell of tubercle is a multicellular nodule, and not as generally believed a single cellular element. When a giant cell is isolated from a tubercular nodule and brought under the microscope, it is seen to be covered on all sides with processes composed of a granular, refracting protoplasm, having a strong affinity for picric acid; the peripheral portion of the cell is occupied by numerous nuclei, while the central portion consists of a granular, refracting mass, which has a very characteristic appearance. Light tapping on the covering glass causes the separation from the mass of the cell of a certain number of cellular bodies, each of which contains one or more nuclei and carries off some of the peripheral processes just spoken of. Other bodies exactly similar to these are only partially separated from the giant cell. The former are evidently epithelioid cells, which have been closely united with the giant cell, while the latter only differ from them in the fact that their connection with the giant cell is still more intimate. In the nuclear zone of the giant cell the lines of junction of these cellular bodies can often be distinctly perceived, but they disappear entirely in the central granular mass. If the tapping be carried on farther, the giant cell is sometimes resolved into a number of smaller masses, each containing several nuclei, and evidently cellular in its structure.

Sections of the giant cells furnished some important information. Three successive cuts of the same cell, which is taken as an example, presented the following

appearances: No. 1 presented a true multinuclear plaque. In the centre of the plaque the nuclei were crowded closely together, but towards the periphery they became more and more sparse. From the periphery extended in all directions a crowd of processes with thick bases and attenuated apices, which were lost in the surrounding tissue. No. 2 presented the giant cell with what may be called its classical characters: centre granular, refracting, and structureless; outside of this a zone of nuclei; beyond this still very numerous processes radiating in all directions. In one place the zone of nuclei was interrupted for a certain space, and at a point corresponding to this hiatus the processes were almost entirely wanting. This fact was taken as a fresh intimation of the intimate relation existing between the nuclei and the processes. No. 3 finally presented a small mass of cellulules with brilliant protoplasm and indistinct contours; at the centre of the mass the cellulules were grouped about a narrow opening which could be followed to a certain depth in the cut. The giant cell varied in size as well as in shape and constitution, in the different cuts. If the volume of the cell in cut No. 3 be taken as the unit of measure and represented by 1, its volume in the second cut would be represented by 3, and in the first by 2½.

MM. Charcot and Gombault think that the facts noted justify the following deductions: First of all, the giant cell tapers towards one and perhaps both of its extremities. Second, both the pedicle and the peripheral zone of the dilated portion of the cell have a purely cellular structure, but in the latter region the elements have undergone a modification, as a result of which they are soldered together by a partial fusion of their protoplasm. The characters of this modification are most marked at the periphery; they consist in the swelling of the protoplasm, its granulated aspect, its tendency to fusion, its peculiar refractive power, and its affinity for picric acid, to the exclusion of carmine. All these different changes, however, are also met with in other parts of the tubercular new-growth, and it is through them that the epithelioid zone of the tubercular follicle is produced. The cells lining the pulmonary alveoli and the endothelium of vessels of a certain calibre, also undergo, under certain circumstances, a similar modification. The nature of this degeneration is unknown, but it may be designated by the term "vitreous transformation," and its effects, as MM. Charcot and Gombault believe, are analogous to what takes place in the peripheral zone of the giant cell. The cellular elements increase in size, the nuclei proliferate, and the protoplasm takes the above characters; then the cells fuse together in greater or less numbers, the lines of separation disappear, and thus structures are formed, resembling to some extent the giant cells. Moreover, it is known, that the ordinary end of this vitreous transformation is caseous degeneration, and the resemblance between the central caseous matter of a tubercular granulation and the central substance of a giant cell is very striking.

From these considerations our observers deduce the conclusion that the central mass of the giant cell had at one time the same cellular structure as has been demonstrated in its pedicle and its peripheral zone, the elements having undergone first an epithelioid transformation, and then caseous degeneration. Hence, it follows that the giant cell is not a single cellular element, but a multicellular nodule, at the centre of which the tubercular process has attained its limit of development.—*Gazette Médicale de Paris*, August 24th.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 1, 1879.

ANTISEPTIC SURGERY.

THERE is scarcely a subject of greater interest to the surgeon, and, it may be added, to the general practitioner, than that of the management of wounds, for upon this often depends the well-being and life of his patient. From the remotest time the care of wounds has received the attention of some of the best minds in the profession, and yet, notwithstanding the advances that have been made in pathological and physiological studies, there is still a want of agreement among practical surgeons in regard to this subject. The low rate of mortality after capital operations, in the practice of some surgeons, cannot be attributed entirely to any peculiar mode of performing the operation, to the pathological condition demanding surgical interference, nor to the condition of the patient—although the two latter elements are no small factors in turning the scale either toward a fatal termination or recovery. There is still another factor, namely, careful personal attention to every detail in the after-management of the case, to which, more than any other, this low rate of mortality must be assigned. Within the last few years a new impetus has been given to the study of the cause of failure of immediate union in wounds, and of the frightful rate of mortality that has prevailed in hospitals at home and abroad, and practical men are now turning their attention more to surgical dressings and the care of wounds than to any new mode of operating or the invention of complicated instruments. The tendency is toward simplifying, rather than complicating, surgical procedure.

The visit of Mr. Lister to this country in 1876 afforded him an opportunity to explain his views on the management of wounds, and since then the Lister plan of the treatment of wounds has gained many advocates in hospitals in this and other cities. It is a matter of record that the mortality, both in hospi-

tals and private practice, has been greatly diminished since the antiseptic treatment of wounds has been adopted. But, while due credit must be given to Mr. Lister for his labors in this direction, we must not shut our eyes to the brilliant results that have followed other plans of management of wounds after operations by other surgeons. We are all liable to be carried away by anything that has an air of mystery about it, or is new, and before we are aware of it we find ourselves advocating and practising modes of procedure that a sober second thought would cause us to reject or greatly modify. That there is much in antiseptic surgery, speaking of it in a general way, no sane man will deny; and the great problem that is being worked out now is, what is essential, and what can be discarded in carrying it out. The aim of every one, when called upon to treat a wound, is to obtain union as by first intention, and in order to attain this there are certain rules of surgery that are as familiar as household words, and which experience has taught us to follow, namely, perfect coaptation of the edges of the wound, and absolute rest. Now, the two disturbing elements preventing primary union, are: 1, tension from effusion of blood or serum, causing separation of the edges of the wound; 2, inflammation and suppuration followed by putrefaction and secondary phenomena, which we designate as surgical fever, pyæmia, and septicæmia. Mr. Lister has demonstrated that by one plan at least, in the majority of cases, these disturbing influences can be prevented, and wounds can be made to heal by first intention without putrefaction with its attendant danger, and that mortality in hospitals can be reduced almost to zero.

The theory on which Mr. Lister insists as the cause of putrefaction, non-union, and its attendant results, is that known as the germ theory, and to prevent these germs from planting themselves in the wound is the aim of all antiseptic precaution.

That wounds will heal perfectly without suppuration, treated upon the old plan, is a well-known fact, and proves that contact with the air is not necessarily followed by suppuration, and even when a wound heals by granulation there is not necessarily any infection of the system. Yet Mr. Lister, and those who have followed closely in his footsteps, have certainly obtained better results than those who have treated wounds on the old plan. But other surgeons, who have treated these amputations in accordance with plans diametrically opposed to the antiseptic method as proposed by Mr. Lister, or who have omitted certain precautions which Mr. Lister has insisted upon as being essential, have had as good results as claimed by those who followed strict antiseptic rules as laid down by him. We think that it is time to examine this question of the treatment of wounds, and see if a careful review of the different methods will not point out what are essential and what may be discarded.

1st. There is the open method introduced by Kern, a Vienna surgeon, and now advocated by Dr. James R. Wood, at Bellevue Hospital.

2d. There is the cotton-wool dressing of M. Guérin.

3d. The modified antiseptic method of Mr. Callender.

4th. The dry dressings of Mr. Gamgee.

5th. There is the strictly antiseptic dressing, so-called, of Mr. Lister.

Dr. Dennis, in describing the open method as advocated by Dr. Wood, states: The cardinal principle involved in this method of dressing is that of preventing suppurative fever, and this object is best obtained by leaving the stump entirely open, thus allowing free and continuous drainage. There are no sutures used; the wound is simply kept scrupulously clean, and every precaution is taken to prevent contamination from any other wound. Carbolic acid is freely used. By this plan Dr. Wood has had fourteen consecutively successful amputations of limbs in a ward that had been vacated the previous year in consequence of puerperal fever, and in a hospital whose sanitary condition has always been considered bad.

M. Jules Guérin, in 1875, adopted raw cotton as a dressing for wounds, filling the cavity with small masses applied accurately to every part of the surface, and then layers of wadding were applied over and around the stump, and over all a bandage was put on with great care, with as much compression as possible, the wound being first thoroughly washed with some germ-killing fluid. He found it the best plan to leave the dressings on for two weeks without change, and if the discharge appeared through the cotton, to apply another layer. His results were much better than that of other surgeons in the same hospital, treated upon the old plan. Dr. Wood and M. Guérin did not aim at primary union; their plan was to prevent accumulation of fluid in the cavity of the stump.

The aim of Mr. Lister was, first, to prevent any contamination of the parts by contact with germ-laden air from instruments in the hands of the operator or his assistants; second, to obtain primary union and to secure perfect drainage, and to prevent putrefaction from the pus coming in contact with the air. The methods insisted upon by Mr. Lister are so well known that we need not enumerate them. Mr. Callender, at St. Bartholomew's Hospital, has for some years adopted the following method of dressing wounds: he uses torsion on all the arteries; he then brushes the cut surface with a forty-grain solution of chloride of zinc, or one to twenty solution of carbolic acid. He carefully unites the edges with silver sutures, and inserts drainage-tubes to relieve all tension; over the wound he places a piece of lint soaked in a solution of carbolic acid and oil, one to twelve, and surrounds the whole with cotton wool. He puts the parts abso-

lutely at rest, not only the limb, but of the system, by the use of opiates. Under this plan he has had twenty consecutively successful cases of amputation of the thigh, and, out of thirty amputations of limbs during a year, had no fatal case.

Lately Mr. Gamgee has advocated what he calls the treatment of wounds by dry and infrequent dressings, rest, and pressure. He unites the edges of the wound with silver sutures, places a gauze and oakum pad over the wound, provides for perfect drainage by rubber tubing; he then envelops the part in cotton-wool, and applies a splint, if it be a limb, so as to insure absolute rest to the parts. In this way he treated a wound into the knee-joint, and when the dressings were removed on the ninth day the wound had entirely healed. There had been no pain or elevation of temperature. We might refer to other methods of treating wounds, but the above will suffice for our purpose. Let us turn for a moment to these five methods and see what is common to them all, and in what they differ, and *first* they all insist upon *perfect drainage, cleanliness, and rest*. Messrs. Callender, Gamgee, and Lister, in addition, insist upon perfect coaptation. Mr. Lister alone is an advocate of the spray, and considers it of as great importance as his drainage or antiseptic dressings. The plan of Mr. Lister is expensive, requires considerable experience, and more personal supervision than any of the other methods, and at the same time more handling of the parts; and the question naturally arises, Is it superior to any of the others, and cannot equally good results be obtained by a modification? And first we would again refer to the results of Dr. Wood's experience at Bellevue in proof of the fact that contact with the air is not necessarily followed by surgical fever, and that cleanliness with exposure to the air will prevent putrefaction—the same may be said of Green's method; the objection to these plans is that they do away with primary union, and therefore keep the patients longer under treatment.

Mr. Callender's mode of treating wounds may be said to be antiseptic without the spray. His results at St. Bartholomew's Hospital, after capital operations, have never been equalled. As a further proof that the spray can be done away with, the plan of treating compound fractures by Mr. Lister himself is to the point, as proving that washing out a wound with a one to thirty solution of carbolic acid gives as good results as are obtained by the use of the spray in operations, notwithstanding the fact that there is usually considerable laceration of the soft parts, and often foreign substances in the wound in compound fractures. If we mistake not, Mr. Bryant's plan of sealing up the wound in compound fractures with Tr. borzein co. was attended with marked success, even without washing out the wound with a solution of carbolic acid.

Experience seems then to point to a modification of

Mr. Lister's antiseptic plan. There is a growing conviction that the spray can be dispensed with, and that a thorough washing of the cut surfaces with an antiseptic fluid will accomplish the same end. Again, some surgeons omit the gauze, others use only a few layers in the place of eight, as insisted upon by Mr. Lister; some are trying other absorbents, as jute, etc.; but the end aimed at by all is the same, namely, to obtain perfect drainage, cleanliness, and rest. If we were called upon to decide what was the most important element in Mr. Lister's dressing, we should say that it was his system of drainage, and to this more than anything else must be attributed his success. This, together with cleanliness and rest, is the principle common to all methods of dressing wounds, and to this conclusion the experience of surgeons here seem to point.

Mr. Spencer Wells says, in regard to this point: "With regard to the spray, I have very grave doubts myself whether it is an essential or useful part of antiseptic treatment In a word, let us regard antiseptic treatment not as a substitute for those measures which have already proved effectual, but as an additional safeguard." The old rules of surgery that have stood the test of years are as true now as ever, and all advance we may hope to make is in more perfectly carrying out the indication they point out, namely: perfect coaptation, perfect drainage, cleanliness, and absolute rest. Antiseptic treatment is only so far an advance in the right direction as it aids us in carrying out more perfectly these rules.

ANTHROPOLOGICAL STUDY.

A RECENT examination of the body of a male chimpanzee in Philadelphia, by Prof. Leidy, of the University of Pennsylvania, is a matter of interest to anthropologists generally. It will be recollected that within the past year we had occasion to notice an examination of a similar specimen by Prof. E. C. Spitzka, of this city. The examination by Prof. Spitzka was the first one of this kind that was made of the brain of the chimpanzee, and established some important facts relating to the development of this organ. In his specimen the dimensions, the outline, and the proportions of the brain were similar to those of the newborn infant, as might be inferred from the size and the shape of the cranium. There were, however, several distinctive features which became apparent on careful examination. The cerebrum overlapped the cerebellum, consisted of the same number of lobes as in the human subject, was as rich in convolutions as the brain of the Bchhuana, and possessed an island of Reil, with the addition of an operculum for the occipital lobe. The trapezium was absent, as in the human subject, and the olivary bodies were present, the latter being well developed and causing the usual prominence of the medulla.

The dissection made by Prof. Leidy bears out the conclusions reached by Prof. Spitzka, so far as the general conformation of the brain is concerned.

We have learned incidentally that an examination, made a few weeks since by Dr. H. C. Chapman, of Philadelphia, of the brain of a female chimpanzee, presented some marked anatomical differences from those recognized in the male specimens. It is presumed, however, that these differences are more in degree than in kind, and possibly may be explained upon the supposition that the brain of the male specimen is better developed than that of the female. From all accounts it would appear that the brain examined by Prof. Leidy was an unusually large one, as it is reported that the cerebellum was quite, if not entirely covered by the cerebrum. But the marks of differences between the male and the female specimens are more noticeable when the conformation of the vocal organs is considered. The male, who is noted for his loud and piercing cry, possesses the anatomical peculiarity of a natural bagpipe, which communicates with the larynx, extends to the breasts, into the arm-pits, and is covered by powerful muscles. The other organs of the bodies examined presented no peculiarities worthy of notice. We are glad to learn that Prof. Leidy will make a detailed examination of the body, and present the results in a paper to the Academy of Natural Sciences. Such a subject in the hands of this distinguished anatomist cannot fail to be treated in a manner which will be highly satisfactory to all who are directly or indirectly concerned in the study of anthropology.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

SURGICAL SECTION.

Stated Meeting, January 14, 1879.

DR. STEPHEN SMITH, CHAIRMAN.

GROWTHS AND FOREIGN BODIES IN THE AIR-PASSAGES; DIAGNOSIS AND SURGICAL TREATMENT.

DR. LEAMING introduced the discussion upon the above subject by reporting a series of cases.

CASE I.—In 1860 a gentleman called upon him and told the following story: While running, with a ten-cent piece in his mouth, to catch a ferry-boat, the coin slipped and passed downwards. He had a slight cough when it first went down, but no violent symptoms. The accident happened in the morning, and late in the afternoon he called at Dr. Leaming's office. The symptoms were so slight that the doctor thought the man had swallowed the coin, but the patient insisted that he could hear something in his chest. On listening carefully at the junction of the third rib with the sternum, a certain sound could be heard, as of something turning over. Such a sound could be heard after the

occurrence of several respirations. Dr. Leaming then had no doubt that the coin passed into the trachea and lodged upon the right side at the septum, and did not completely shut off respiration upon either side at any time. He thought the residual air in the lung was sufficient to turn the coin over at certain intervals, and in that way explained the peculiar sound that could be heard upon auscultation, and also by the patient himself.

According to a plan of treatment adopted by an English surgeon, the man was advised to get upon a bed and then turn himself quickly upon the floor. The moment his head was thrown downward the coin flew out of the mouth and struck the floor with considerable force.

CASE II.—A man was brought into St. Luke's Hospital in a state of suffocation, on account of a gummy tumor of the larynx.

Dr. Gurdon Buck performed tracheotomy at once, and the patient was immediately relieved. On the following day an operation was performed for the removal of the tumor. The patient continued to wear the tracheotomy tube and its shield. One night he awoke suddenly with a feeling of strangulation. On examination it was found that the shield was *in situ*, but that the tube had disappeared. The house-surgeon searched for the tube, but was unable to find it. It was supposed that it had reached the stomach, because the violent symptoms had subsided, and the patient was quite comfortable. He had been in that condition several days when Dr. Leaming saw him, and upon making a physical examination of the chest he was able to detect an abnormal sound upon the right side. A whistling sound could be heard over the middle and upper part of the interseapular space. In that region and over a space about an inch and a half in length, and about an inch in width, a peculiar whistling sound could be heard. It was believed that the tube had passed into the bronchi and lodged in the cul-de-sac of the first division. It was removed by an operation, and the patient recovered.

CASE III.—The third case was seen with Dr. Jones. A man standing in a stable was chewing a stalk to which a timothy-head was attached. He suddenly coughed, and, with the forcible inspiration which as quickly followed, the timothy-head sailed through the larynx and passed into a bronchus before it was arrested.

Circumscribed pleurisy was developed upon the right side, and three inches above the diaphragm a line of pleuritic râles could be heard from the sternum to the spine. Above that point the lung was free. When he found that the lung was free down to that point, he made the diagnosis that the timothy-head had penetrated the pleura and passed into the liver. The diagnosis, however, was wrong. The man lived about one week. In the meantime the timothy-head was thrown up in an act of coughing and vomiting. At post-mortem it was found that adhesions had occurred between the pleural surfaces upon the right side, and that a sac had been formed with a valvular opening, so that when closed no breath sounds could be heard below a certain line; but when the patient coughed it would be free, and then sounds could be heard below. The entire lung was destroyed, and hay-seeds were found scattered throughout the lung-tissue.]

CASE IV.—A boy, who was holding in his mouth a collar-button, attempted to speak to another boy, and as he took a breath the stud passed through the larynx and down into a bronchus. He coughed considerably

during the same night, but subsequently not very much local disturbance was produced. On auscultation a double whistling sound was heard in front, at the upper portion of the fourth intercostal space, and also behind; more distinctly, however, in front. It was believed that the button had passed down until it reached the *third* division of the right bronchus, and there lodged with the shank across the septum, so that the bronchial tube was dilated by the projecting extremities.

Evidences of pleurisy were developed, and were followed by those of lung consolidation.

After the lapse of some months, Dr. Markoe opened the trachea, introduced a probe, and loosened the body, and then removed it with a pair of curved forceps.

The boy quickly rallied from the constitutional disturbance produced by the foreign body, and made a good recovery. As soon as the operation was performed the double whistling sound disappeared.

CASE V.—A portion of a peach-stone passed into the right bronchus. In that case no distinct adventitious sound could be heard; but over a portion of the lung there was complete absence of respiratory sound. An effort was made to dislodge the body by elevating the heels and lowering the head, but it failed.

An operation was advised, but the family objected. Pleurisy followed. After a time, during a violent fit of coughing, the foreign body was thrown out covered with mucus.

A second case in which the foreign body was a portion of a peach-stone, was also mentioned.

CASE VI.—In a hospital patient, blood from an operation about the mouth trickled down into both bronchi.

At first there was simply severe and constant coughing, but little or nothing was expectorated.

At the end of two or three days pleuritic râles could be distinctly heard upon the right side over a limited space, and soon the same kind of râles could be heard upon the left side of the chest. Subsequently it was readily determined that consolidation of lung-tissue had occurred. Death took place on the sixth day. At post-mortem, consolidation of lung-tissue was found, small abscesses in direct connection with the clots, evidences of older pleurisy, and a large amount of plastic material at the lower portion of the pleural cavity.

CASE VII.—A hospital patient, upon whom an operation affecting the jaw was to be performed, suddenly vomited while a tooth was being extracted. The tooth slipped from the forceps and disappeared. The patient coughed considerably on the next day, and also on the day following, when Dr. Lefferts, then house-surgeon, made the diagnosis that the tooth had entered the air-passages, had lodged in the left bronchus, completely obstructing it.

Evidence of pleurisy followed, and subsequently evidence of lung consolidation. The entrance of air into the left lung was completely prevented until abscesses had formed, when air could be heard passing the tooth. No operation was performed for the removal of the foreign body. The case terminated fatally.

At autopsy the tooth and abscesses were found as diagnosed.

When the obstruction was such as to completely prevent the entrance of air into the lung, the complete absence of respiratory sound could be taken as evidence with regard to the position of the foreign body. That might occur with such a body as a tooth.

With such irregular bodies as coins or tubes, or buttons, their position could be determined by the location of the sound produced by the air as it passed them, provided they were above the residual air.

The first lesion in the case in which blood had passed into the bronchial tubes was the pleurisy.

Dr. F. V. WHITE asked Dr. Leaming how he explained the common occurrence of the pleurisy in the cases reported?

Dr. LEAMING replied that the sympathy between the bronchial tubes and the pleura was very marked, and that irritation of the bronchi was very commonly followed first by pleurisy and then by pneumonia.

Dr. WEBER remarked that he was not able to accept the explanation of the occurrence of pleurisy, after the lodgement of foreign bodies in any part of the bronchial tube, upon the basis of sympathy between the bronchial tubes and the pleura. The foreign body doubtless would cause local irritation, and in response to that irritation a certain kind of pneumonia might be developed, which would rapidly extend, and produce a certain amount of pleurisy. There might be sufficient pleuritis to give rise to friction-sounds, but he believed that it was preceded by pneumonia; that the pneumonia existed, but was not sufficiently well developed to give rise to bronchial breathing. If the occurrence of the pleurisy was to be explained upon the basis of sympathy between the bronchial tubes and pleura, pleurisy should be a common complication of bronchitis.

Dr. LEAMING remarked that bronchitis and pleurisy were very frequently associated with each other.

Dr. WEBER thought it impossible that such an opinion could be correct.

Dr. POST referred to a case in which a persimmon seed passed into one of the bronchi, and there remained for a long time. The patient, one of his former pupils, had a cough, which was attended by a purulent expectoration and emaciation, and he presented the appearance of one suffering from pulmonary consumption. Hectic fever was well marked. Finally, during a violent fit of coughing, the foreign body was ejected, and the patient made a good recovery.

He further remarked that, in the English case referred to by Dr. Leaming, tracheotomy was first performed in order to avoid suffocation from spasm of the glottis in case the coin was dislodged and passed through the larynx. For the removal of such bodies as smooth pieces of coin, the operation and the sudden change in the position of the patient was proper; but if the foreign body was irregular in shape, and rough, probably not much could be accomplished in that manner.

Dr. STEPHEN SMITH asked if it would be proper to perform tracheotomy in cases in which the coin was no larger than a ten-cent piece?

Dr. LEAMING thought it would be well to have a surgeon ready in case the operation became necessary.

Dr. POST believed that it was better to first perform tracheotomy as a matter of safety, for the operation was not a dangerous one, and in case spasm of the glottis was produced by the foreign body, the patient might die from suffocation before relief could be afforded.

Dr. WEBER thought it proper to first perform the operation of tracheotomy.

Dr. POST referred to a post-mortem examination which he made many years ago upon the body of a child who died in consequence of the inhalation of a piece of a peanut-shell into the trachea. Some time previously the child had swallowed the fin of a fish. The forcing body had perforated the intestine, had

become surrounded by a band of false membrane, forming such attachment as to leave an opening through which, in a violent fit of coughing caused by the peanut-shell in the trachea, a large mass of intestine was forced, and then became strangulated.

Towards the close of the case the abdominal symptoms masked the thoracic symptoms.

In this connection mention was made of Dr. Buck's case, in which a fish-bone remained in the air-passages fifteen years, and was then expelled by coughing.

Dr. ROBINSON referred to the value of the laryngoscope in deciding that the foreign body was *not* in the larynx. He also inclined to the opinion that more recent observations had proven that it was not well to operate for removal of foreign bodies from the bronchi, for the reason that a greater number recovered when left to the efforts of nature.

Dr. GARRISH referred to a case in which a cherry-stone dropped into a gentleman's mouth and disappeared. About four weeks afterwards he began to cough and expectorate, his health began to decline, and he became extremely emaciated.

At the end of eight or nine months the doctor saw him, and prescribed a cough mixture, which happened to cause the patient to vomit. While vomiting, the cherry-stone was thrown out, and from that time the man began to improve, and made a rapid recovery.

Dr. BURRALL regarded the laryngoscope as a valuable instrument to give us negative evidence in these cases, when it could be employed.

He referred to a case in which a needle was swallowed and became fastened in the throat, and in that instance he thought he made a practical deduction. The spasm was so great that the laryngoscope could not be used. The needle could be touched with the finger. The finger in the throat excited efforts to vomit, and with each effort the needle was raised, but not expelled. Firm pressure depressed the posterior part of the larynx, so as to increase the space, and after two or three efforts at vomiting the needle was expelled.

In the previous efforts the larynx had been raised against the pharyngeal wall, and so occupied the space that the needle could not be removed.

Dr. WEBER reported a case in which, at the request of another physician, he performed laryngo-tracheotomy for the purpose of permitting the removal of a growth from the larynx. The subsequent history of the case proved that the patient had cancer of the œsophagus. In consequence of the pressure produced by the growth in the œsophagus the mucous membrane of the larynx presented a tumefied appearance, which led the physician to believe he had to deal with epithelioma of the larynx.

The Section then adjourned.

Stated Meeting, February 11, 1879.

COMPOUND HARE-LIP.

Dr. JAMES L. LITTLE presented three cases of compound hare-lip with cleft palate. The patients were three brothers, aged 22, 18, and 9 years. The father was born in England, the mother was a native of the United States. No deformity could be traced upon either side. The family consisted of nine children, who were born as follows: First, a boy, with compound hare-lip and cleft palate. Second a girl, without deformity. Third, a boy, with compound hare-lip and cleft palate. Fourth and fifth, two girls without deformity. Sixth, a boy, with compound

hare-lip and cleft palate. Seventh and eighth, two girls without deformity. Ninth, a boy, who lived only a few hours, but was born with compound hare-lip and cleft palate. Four boys and five girls; all the boys born with deformity, and all the girls without deformity.

The only external deformity in the family, aside from the hare-lip, was absence of the ring-finger, and a peculiar twisting of the little finger, on the right hand of John Bocoock, which gave it somewhat the appearance of a thumb. The index and middle fingers were also larger and longer than corresponding fingers upon the left hand.

On Wm. Bocoock, *et.* 22 years, four operations were performed. His lip before the operation had a wide cleft, the intermaxillary bone projected and held one incisor tooth, and there was fissure of the hard palate. The first operation was to close the fissure in the hard palate, and was only partially successful; the soft palate separated entirely, and the covering for the fissure in the hard palate almost entirely.

The second operation consisted in removing the projecting portion of the intermaxillary bone, and forming a septum for the nose with the integument by which it was covered. The operation was successful. Subsequently, an operation was performed upon the double hare-lip. That operation was followed by an attack of erysipelas, and was only partially successful.

Lastly, what is known as Nelaton's operation was performed, and the result was very satisfactory.

On John Bocoock, *et.* 9 years, two operations were performed. The intermaxillary bone projected and carried two incisor teeth. A septum was formed for the nose in the same manner as in the first case, and the operation was successful. Subsequently an operation was performed upon the double hare-lip, and the result was very satisfactory.

Chas. Bocoock, *et.* 18 years, had a very wide cleft in the mouth, but the projection of the intermaxillary bone was not so prominent as in either of the other cases. Dr. Little proposed to operate after the same general plan by which he had been guided in his operations upon the other patients.

Dr. Post exhibited a *daguerrotype* of a patient thirteen years old, upon whom he had operated for the correction of a deformity that equalled the worst features of any case which Dr. Little had presented. The result was such that no indentation was left in the margin of the lip. He thought it very important to make the incisions so that when the edges were brought together there would be considerable pointing at the junction on the margin of the lip. There was no danger of bringing too much material to that point.

Again, operations performed upon adults or half-grown children were usually followed by better results than in small children. The parts could be brought into more perfect apposition, etc.; still, it was not desirable to allow children to grow up with such a deformity. In cases in which there was fissure in the bony structure, early closure of the fissure in the lip exercised a certain amount of pressure, and diminished the breadth of the cleft in the hard palate.

Dr. Wm. T. White referred to a family in which three of the children were born with hare-lip and fissure of the palate. All died within a few days after birth.

Dr. Post referred to a family reported by Dr. Buck, in which the mother and five or six children had hare-lip.

Dr. Garrison referred to four families in which

there were three children in each family who had hare-lip, either compound or simple.

Dr. Wiener referred to a family in which two children born of the first wife had compound hare-lip, but in none of the children born of the second wife did the deformity appear.

He thought it was next to impossible to secure such perfect coaptation of the parts at the first operation as could entirely correct the deformity. He had never seen a case in young children in which it was not necessary, after the child reached ten or twelve years of age, to operate to remedy the indentation in the margin of the lip.

With reference to closing the fissure in the hard palate, he thought an operation should be avoided, because the dentists had succeeded so well in making an artificial roof of the mouth, and at the same time the operation was quite commonly unsuccessful.

Dr. Little thought if the operation could be performed it was usually successful, and believed it to be bad advice to send such patients to the dentists. There were comparatively few patients who could bear the expense of the artificial appliance. In order to secure the best results so far as indentation in the margin of the lip was concerned, he thought it very important to secure perfect coaptation at the *upper* edge of the vermilion border.

Dr. Wiener referred to a case in which an opening in the hard palate about three-fourths of an inch in diameter was successfully closed by a button made of gutta-percha. The girl had learned to mould one herself, and made a new button as often as the old one became hard and gave her any discomfort. An artificial appliance was thus afforded which answered all practical purposes, and the expense was a mere trifle.

Dr. Post thought it well confirmed that a properly formed artificial palate was more useful than a united velum, and was preferable if the patient could afford the expense.

Dr. Little's communication was referred to the Academy.

DEFORMITY PRODUCED BY A BURN.

Dr. A. C. Post presented a cast representing the hand of a child two years old. At the age of eight months the child received a burn by falling upon a stove. The injury was followed by a deformity. The hand was bent forcibly backward, and the only part not seriously injured was the thumb and the ring finger. Dr. Post operated by first dividing the cicatricial mass upon the back of the hand, and then dissecting out the little finger, and bringing it into parallel position with the ring finger. The index finger was atrophied and unfit to preserve, therefore the bones were removed and the skin was used as a covering for the middle finger, which was dissected out from the cicatricial tissue upon the back of the hand. He succeeded in obtaining a hand which did not present much deformity except that it had only three fingers, and one of these was considerably increased in size. To diminish the size of the finger another operation was to be performed. Dr. Post believed he had proved that the tendency to contraction in cicatricial tissue following a burn could be overcome, but in order to accomplish it great perseverance was necessary.

REMOVAL OF FOREIGN BODIES AND GROWTHS FROM THE AIR-PASSAGES.

Dr. Clinton Wagner confined his remarks upon this subject to the removal of foreign bodies and growths from the larynx. With reference to lodge-

ment of foreign bodies in the larynx, according to his experience, it was exceedingly rare. In such cases if the foreign body could be seen by the laryngoscope, he would not be in haste to perform tracheotomy unless death from suffocation was imminent. He preferred to wait until tolerance had become established, and later on try to remove the foreign body by means of Mackenzie's forceps with the aid of a laryngoscope. He then referred to a case published in the *London Lancet* several years ago, in which a piece of bone one inch in length by three-fourths of an inch in breadth was successfully removed in that manner. With reference to growths in the larynx, his experience had been more extended. Nineteen cases had come under his own observation. In those cases he thought tracheotomy should not be performed unless breathing was interfered with, or death from spasm of the glottis was apprehended. Removal *per vias naturalis* should always be first tried.

With reference to preliminary treatment in such cases, he thought its necessity had been greatly overestimated. He rarely adopted any preliminary treatment, and made an effort at once to remove the growth. If unsuccessful the first time, he repeated the operation after the lapse of a few days. He never pressed the use of the forceps for a longer period than ten minutes at a single sitting. In the hands of one accustomed to their use, he thought Mackenzie's forceps devoid of danger. It had been claimed that lacerations, paralysis, perichondritis, or chondritis were apt to follow their use, but he had not seen any such unfavorable results.

In cases in which the growth had been allowed to increase in size to such an extent as to interfere considerably with respiration, no time should be lost by attempting to remove it through the mouth, and the extra-laryngeal method became necessary.

To summarize: in all cases of intra-laryngeal growths, removal through the mouth should be attempted, and he had not seen a case in which removal through the mouth could not be effected when the growth was situated above the vocal cords. The extra-laryngeal method of removal should be resorted to only when death was imminent from spasm of the glottis.

DR. GARRISH exhibited Dr. Physick's instrument for removing foreign bodies from the throat and œsophagus.

ENLARGED LYMPHATIC GLANDS—IODOFORM AND COLLODION.

DR. BURRALL referred to a single case in which there was a marked improvement in the general condition, and a diminution in the size of a bunch of enlarged lymphatic glands situated at the base of the neck in a scrofulous patient. The favorable change was apparently produced by applications of *iodoform dissolved in collodion*, one part of iodoform to fifteen of collodion, as recommended by Moleschott. He thought the remedy was worthy of a trial.

The Section then adjourned.

CORYZA.—Dr. Rudolpho Rudolphi recommends the use of eucalyptus globulus for the rapid cure of acute coryza, or cold in the head. He has found, by numerous trials on himself and patients, that after chewing a few of the dried leaves and slowly swallowing the saliva, the affection is promptly relieved, often disappearing in the course of half an hour. The remedy is useful in acute cases only.—*Gazz. Med. Ital. Lombardia*, January, 1879.

Correspondence.

THE AMERICAN PUBLIC HEALTH ASSOCIATION AND THE WITHERS BILL.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your editorial comment on the excellent letter of Dr. B. F. Gibbs, published in the *MEDICAL RECORD* of the 15th inst., you have adverted to the fact that the Withers Bill, based upon a recommendation of the Executive and Advisory Committees of the American Public Health Association, and supposed to embody their views, leaves the whole matter of sanitary legislation virtually in the hands of an extra-medical scientific body, though the aforesaid authorized representatives of the Association had only asked that the Academy of Sciences should designate the members of a Provisional Health Commission who should be charged with the duties now proposed to be assigned to that Academy.

Whether the Association is willing to father the bill as it now stands may admit of a difference of opinion, but that the committee charged with this duty had no alternative, and that they acted within the limits of their delegated powers, will clearly appear from a brief statement, which I trust will satisfy both the Association and yourself.

This committee, consisting of Dr. J. M. Toner, Chairman, Dr. J. S. Billings, and Gen. Eaton, Commissioner of Education, having prepared a bill in strict accordance with the section of the memorandum cited by Dr. Gibbs, requested me to show it to two members of Congress who were expected to be the patrons of the measure, and to request them to present it to their respective wings of the National Legislature. In conferring with these and other friends in Congress, I was at once informed that there were grave constitutional objections to that feature of the bill which required Congress to delegate to parties outside of the Government the authority to appoint a Governmental Commission, and that this difficulty would be obviated by calling on the Academy itself to report to Congress a plan for a permanent Public Health Organization. When this was made known to the committee they promptly and unanimously decided to modify their bill in accordance with the suggestion and advice of our friends in Congress. Though not *ex-officio* a member of the sub-committee, I, as representing in part the Executive Committee of the Association, did not hesitate to take a full share of the responsibility that might attach to this departure from the precise plan indicated in the "Memorandum." In point of fact there was no alternative, as that plan had been rejected by those very members of Congress by whose aid alone we could hope to succeed in our efforts to secure desirable legislation, and we were shut out from falling back on the Lamar Bill, or any similar bill, by the express declaration of the "Memorandum" that "political or local considerations should have no weight in the matter, nor, unless there are grave legal or constitutional objections, should any officer of the Government be burdened with, or allowed to assume the responsibility of selecting" the members of the commission.

Some objection to the bill as it now stands is based upon the implied assumption that the National Academy of Sciences is composed exclusively "of gentlemen who have never given any attention to the subject, and whose studies are confined to astronomy, geology, entomology, and kindred subjects." This

is a most unwarrantable assumption, not at all sustained by the actual facts. I understand that every branch of science is represented in the membership of the Academy, and that its *personnel* includes several gentlemen who have a recognized position among the sanitarians of the United States, such as Dr. J. J. Woodward, of Washington, Dr. S. Weir Mitchell, of Philadelphia, Dr. J. C. Dalton, and President F. A. P. Barnard, of New York. Doubtless there are several others, but as I have not the list before me, I cannot now certainly specify them. I understand further, that when any subject is referred to the Academy by Congress, as for example, the question of the proposed consolidation of the various surveys, it is the custom to appoint a special committee composed of such members as have made a special study of kindred subjects.

Moreover, the bill to which you take exception, expressly requires that the plan for a permanent Public Health organization, to be reported to Congress by the Academy, "shall be prepared after consultation with the principal sanitary organizations and sanitarians of the several States, and of the United States, and shall be accompanied by the evidence of their opinions and recommendations."

With such adequate safeguards against incompetent handling of the subject, and against abuse of the special authority proposed to be conferred on the Academy, I cannot doubt but that the measure will meet with very "general approval among the scientific and professional men of the country." I am, very respectfully,

J. L. CABELL, M.D.,

President Am. Pub. Health Association.

UNIVERSITY OF VIRGINIA, February 17, 1879.

THE TREATMENT OF ACUTE ARTICULAR RHEUMATISM.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In a recent number of your journal Professor Stillé makes the remarkable assertion that "no treatment was ever invented that stopped a case of acute articular rheumatism," and that therefore the cure may be abandoned "to nature, aided by palliatives." Had this statement been enunciated thirty years ago, little would have been thought of it; at this day a good deal will not only be thought about it, but probably written on the subject. My attention was early drawn to this painful affection from its prevalence in my own family; and the plan of leaving the cure to nature in a second attack, by the skilful physician who then attended our family, resulted in the death of the patient from endocarditis. Having shortly after the time alluded to engaged in practice myself, I treated another member of my family suffering with an extremely acute attack, and succeeded in decidedly shortening the period of his confinement to bed. The plan then in vogue—now nearly twenty years since—was crude as compared with the facilities we now possess, yet notable success always ensued in all cases *promptly* and *thoroughly* treated. The fact that various methods were urged by different authorities did not at that time militate against their value, for rheumatism, as any other disease, may be relieved or cured by more than one plan of treatment. After seeing a fair amount of rheumatic fever during nine years of army life, I came back to this city, in time to find the second case referred to convalescing from a bad attack which lasted *thirty-seven* days under "expectant" treatment in the hands of a well-known

Walnut Street practitioner. The next attack set in with violent symptoms, intense pain in all the articulations of the lower extremities, and in nearly all those of the upper extremities. I saw him twenty-four hours after taking to bed—his temperature $102\frac{1}{2}^{\circ}$, rapidly mounting to 104° before remedies could be thoroughly applied. There is no necessity for going into the daily symptoms, so much has already been published concerning salicylic acid as to make repetition useless. Suffice it to say that, under twenty-grain doses of salicylate of sodium, in forty-eight hours the temperature was reduced to the normal point, the pain was gone, the inflamed joints were free from swelling, not productive of agony when handled, and the patient—who was anxious to return to his business as soon as possible—was out of the house in seven days. More than that, he has never since then (1875) had a touch of his old enemy. This case is one out of many, and with uniform success in upward of a hundred cases since that time. Much as I respect the opinions of the distinguished Professor, I cannot help differing decidedly and strongly from his statement. The experience of physicians in many thousand cases has proved the value beyond question of the salicylates, and in closing I do not hesitate to say that in the salts mentioned we possess against rheumatism as decided a specific, and more so, than we do in quinia against the so-called malarial fevers.

WM. R. D. BLACKWOOD.

246 N. 30TH STREET, PHILADELPHIA.

UNGT. VASELINI PLUMBICUM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—This preparation, referred to on page 168 of the RECORD as highly recommended by Prof. Kaposi, of Vienna, was published by him as new, in the *Wiener mediz. Wochenschrift*, No. 17, 1878. In the Transactions of the New York Dermatological Society, of April 11, 1876 (*Archives of Dermatology*, July, 1876), will be found the following: "Dr. Piffard showed some diachylon ointment prepared by melting together equal parts of the emplastrum plumbi and vaseline, working the mass in a hot mortar till cold. The preparation was very soft, and apparently a perfect combination. He had used it successfully in *eczema*." As this is not the first time that my own and other American work has been deemed worthy of notice in this country only after it has been appropriated, without credit abroad, I trust you will pardon this trespass on your space.

Respectfully yours,

H. G. P.

DR. BOZEMAN'S REPLY TO DR. SIMS'S LETTER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the letter of Dr. J. Marion Sims, published in the RECORD of February 8th, purporting to explain his operations in Vienna for the cure of cancer of the cervix uteri, he asserts that I did not perform any such dangerous operations while I was there, but confined myself to the simpler ones of vesico-vaginal fistula, of which he himself performed only one, and then institutes a comparison of our respective modes in these words:

"The only comparison I heard made in Vienna between my single operation for vesico-vaginal fistula and Dr. B.'s numerous ones was this: that I took only

hours instead of weeks to prepare a contracted vagina for operation; and that I took only thirty minutes to operate on a difficult case of vesico-vaginal fistula instead of three hours; and that the position of the patient for operation and the whole method of operating were in accordance with correct surgical principles, and void of pretension and mysticism."

Now, whether my operation for vesico-vaginal fistula deserves to be characterized by Dr. Sims as full of "pretension and mysticism" or not, I leave to the readers of the RECORD to decide. I must, however, positively protest against any such unwarranted and unprofessional reflection upon my character and reputation, calculated as it is to injure my standing in the profession.

I wish simply to call attention to two points contained in Dr. S.'s letter to the RECORD: first, to the adroitness by which he tries to cover up his failures and humiliation in Vienna, in the face of published and positive proof to the contrary, by saying that only two out of the three cases operated upon there by him for cancer of the cervix uteri died, instead of all three; and, second, to the adroitness by which he tries to make it appear, in the face of published and positive proof to the contrary, that the result of his only operation in Vienna for "contracted vagina" and vesico-vaginal fistula was of far more practical value than my numerous ones, because he required "only hours" to make the necessary preparatory treatment, and "only thirty minutes, instead of three hours" to close the complicating fistula, referring here to the time taken for the same purpose in my Case II., the worst of the four cases that I entered for Professor Brown at four operations.

With regard to the first point, let us read what is said of it by the Vienna correspondent of the *Chicago Medical Journal and Examiner*, September, 1878, who wrote under date July 15th, who was on the spot and who was in daily communication with Professor Salzer, whose service furnished the patient of reputed recovery, from six to eight months after all these cases of cancer were operated upon by Dr. S.: "Dr. Sims's patients operated upon here all died of peritonitis within ten days of the operation. I remarked to the Professor, who related the facts to me, that I supposed they selected desperate cases for Dr. Sims to operate upon. He replied, that although the cases were bad ones, that did not alter the fact that they had died of the direct effects of the operation."

With regard to the second point, it is only necessary to refer to the report by Dr. Ludwig Baudl, of my four cases of contracted vagina with vesico-vaginal fistula operated upon in Vienna, a translation of which from the *Wiener med. Wochenschrift* is to be seen in the *Richmond and Louisville Medical Journal* for November and December, 1877, and especially that of Case II. of mine, singled out by Dr. Sims for comparison with his case. This case, aged thirty-two, presented a vesico-utero-vaginal fistula, measuring five centimetres transversely and four longitudinally, about the size of a silver dollar; and a recto-vaginal fistula the size of a quarter-dollar, 11.5 centimetres from the perinaum. There was a broad, thick, and unyielding cicatricial band that encircled the vagina, and the left angle of the fistula was adherent to the posterior surface of the pubic bone. There was also complete immobility of the uterus. Superadded to all this there was a prolapsus of the superior wall of the bladder through the fistula and vulva to the size of a child's fist, and also abrasions and urinary concretions upon the labia.

On June 26th, my first incisions into the cicatricial bands were made, and the dilatation with cylinders of

hard rubber commenced. Four days later the beneficial effects of the treatment were marked, as shown by the mobility of the uterus. The organ could now be hauled down with hooks, so as to place the borders of the fistula in contact about four-fifths of their extent; but the force required to do this, as accurately determined, was 2,800 grammes, nearly six pounds, an amount of resistance which certainly no form of suture could have withstood without cutting out; a repetition of the incisions as required, and gradually increased dilatation, were continued up to the seventeenth day, with the results as here stated by Dr. Baudl.

"July 13th, Bozeman concluded that the proper time for operating had arrived. The patient was secured upon his supporting-chair, chloroform administered, and the urinary fistula exposed to view in a splendid manner by the introduction of speculum No. 1, with the rectal blade. Professors Billroth, G. Braun, Karl von Braun, Spaeth, and many other physicians, were present. The spring-scales showed that now only 120 grammes (about a quarter of a pound) were necessary to approach the upper to the lower edge.

"July 20th, Bozeman proceeded to remove the wires (button suture), remarking, at the same time, that he would be satisfied if there was union only to the extent of five sutures. To our great surprise, however, the fistula was found almost completely closed: only a small opening remained between the seventh and eighth sutures on the left side, through which a surgeon's probe only could be passed into the bladder."

The plan of treatment and result in this case speak for themselves. The amount of resistance actually overcome in thirteen days from the time the estimate of it was made was just 2,680 grammes. I say thirteen days, because it will be recollected that the force was measured four days after my *first incisions*, the only thing insisted upon by Prof. Simon in his plan of *immediate preparatory treatment*, the course pursued in Vienna by Dr. Sims in his simple case. Here there was determined, by accurate mathematical demonstration, the precise difference between the two systems of *immediate and gradual preparatory treatment* four days after my first incisions. Of course, at the beginning of the treatment the resistance was far greater, perhaps double, triple, or quadruple the estimate given. The one system, therefore, in this case was proven, by exclusion, to be wholly inapplicable, even worthless, and the other was proven to be equal to the fulfilment of the highest aims of skill and science.

Then, of what consequence were these seventeen days, and a complete cure with preservation of her generative functions, to this poor woman, compared with the result of the inefficient system of immediate preparatory treatment, or kolpopleisis, advocated by Dr. Sims in his simple and comparatively uncomplicated case? And where is the proof, other than unwarranted assertion, that the procedure employed in her case, from beginning to end, was not "in accordance with correct surgical principles, and void of pretension and mysticism"?

Scarcely need I say it was this result, achieved under such difficulties, that convinced the surgeons and gynæcologists of Vienna of the great value of my operation, as a whole, for vesico-vaginal fistula, and caused them to estimate my labors in their midst in the complimentary manner as published by the Vienna correspondent of the *Chicago Medical Journal*.

A somewhat similar case to the one above related at such length was recently admitted into my service at the New York State Woman's Hospital, though far less

complicated and difficult to treat. Here also the upper border of the fistula, after the division on both sides of the broad cicatricial band, could only be put in contact with the lower by a force that would have resulted necessarily in the cutting out of my suture apparatus. Gradual dilatation, however, soon overcame the inherent resistance, and brought the parts into a favorable condition for closure of the fistula. The operation was performed in the presence of Drs. Noeggerath, Fitch, Janvrin, Goldthwaite, Tausky, and many other physicians, and the cure thus completed at a single operation.

In conclusion, I would say that I never went to Vienna to operate for the cure of cancer of the cervix uteri. Dr. Sims did this, I suppose, and is entitled to all the credit that attaches thereto. I went there simply to demonstrate the value of my system of *gradual preparatory treatment* as a means of curtailing or rendering unnecessary obliteration of the vagina in a very large class of urinary fistulae in women.

Yours very truly,
NATHAN BOZEMAN.

206 FIFTH AVE., NEW YORK. Feb. 15, 1879.

REPLY OF DR. WYETH TO DR. STILLMAN.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The truth settles all questions of priority promptly. After reading your issue of Feb. 22d, I am convinced that my friend, Dr. Chas. F. Stillman, preceded me in the idea of continuous extension. He deserves, and I give him, the credit his genius demands. Up to the time my paper was read before the New York County Medical Society, I had never had the slightest intimation that any other individual had originated or applied the mechanism of continuous extension in this disease. In the discussion which followed, I was informed by Dr. Judson that Dr. Edmund Andrews had some years ago applied an extension apparatus by means of adhesive-plaster strips. I have written to Dr. Andrews, and, when the evidence is all in, the profession shall have the entire truth of it.

The method of continuous extension is now on probation. I am using it, and intend to do so through a few years and give my results. I believe the profession will endorse my claim that I was the first to apply the double plaster jacket with continuous extension, and to demonstrate its usefulness, and that the idea was entirely original.

Yours truly,
JOHN A. WYETH.

Feb. 21, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from February 16 to February 22, 1879.

NOTSON, WM. M., Major and Surgeon. To report in person to the President of the Army Medical Board, now in session in New York City, for temporary duty as a member of the Board. S. O. 28, A. G. O. February 15, 1879.

BIART, V., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort Leavenworth, Kan., to accompany Companies A, C, D, G, and K, 23d Infantry, to their new station (a point on the south side of the North Fork of the Canadian), and remain on duty with them as medical officer of the new post. S. O. 32, Dep't of the Missouri, February 15, 1879.

LA GARDE, L. A., 1st Lieut. and Asst. Surgeon. Granted leave of absence for fifteen days. S. O. 26, Dep't. of the East, February 18, 1879.

Medical Items and News.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Comparative statement of cases of Contagious Diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending February 22, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Feb. 15, 1879.	0	3	207	3	3	63	0	0
Feb. 22, 1879.	0	10	165	1	6	49	0	0

DR. J. P. CREVELING.—The following were the conclusions given by Dr. Creveling, in his paper read before the New York State Medical Society. They differ from those given in our report, and therefore should be substituted:

1st. That abdominal section for the removal of intestinal obstruction is not only justifiable, but eminently proper.

2d. That in cases of intussusception, as soon as all milder means have failed, the operation should be immediately performed, provided the conditions are at all favorable; but if symptoms of strangulation, as peritonitis, hemorrhage, etc., have occurred, the operation is hardly warranted.

3d. That in obstruction from causes other than intussusception, the operation should be performed at once.

4th. That there is not the real danger in the operation itself that has been by many supposed.

CONVENTION OF AMERICAN MEDICAL COLLEGES.—A call has been issued for a convention of all American Medical Colleges to be held in the city of Atlanta, Ga., beginning at 10 A.M., Friday, May 2, 1879. In general terms the object of the convention is to adopt some "uniform system of instruction more in harmony with the requirements of the age." Although called by the "American Medical College Association," it is entirely distinct from that body. Those colleges which decide to attend the convention by delegates are requested to notify the Secretary, Dr. Leartus Connor, Detroit, Mich., at any time previous to April 25, 1879.

FILARIA IN THE EYE OF A HORSE.—Dr. Jesse Harris, of Greeley, Colo., writes that *two* cases of filaria in the eye of a horse have come within his observation. One of the specimens was sent by him to Dr. Prout, of Brooklyn.

THE YELLOW FEVER FUND.—Fifteen hundred (\$1,500) dollars have been sent to Memphis, Tennessee; six hundred (\$600) dollars to Grenada, Mississippi; one hundred and fifty (\$150) dollars to Nicholasville, Kentucky; three hundred (\$300) dollars to Highlands, North Carolina; and eight hundred and sixty-six (\$866) dollars remain for distribution. This balance will be sent to the same places unless new objects for consideration are soon made known to the committee. In addition, by the suggestion of the chairman, the Chamber of Commerce of the State of

New York was, perhaps, induced to turn over their final balance of eleven hundred and twenty-seven dollars and twenty-six cents (\$1,127.26) for the relief of the families of physicians who died in the employ of the Howard Relief Association in New Orleans.

The committee will soon receive twenty-five hundred (\$2,500) dollars from the Chamber of Commerce of this city, and two hundred and fifty (\$250) dollars from the Hon. Mr. Evarts, Secretary of State.

The committee desire all the advice about the final distribution of the above-mentioned sum, viz., three thousand six hundred and sixteen dollars (\$3,616) which they can obtain from the subscribers and others interested. Sixteen families have received aid, and more will be given to them, as they are all deserving and in want; but the committee are anxious that none should be overlooked until it is too late, and respectfully request information from all reliable sources.

J. C. PETERS, M.D., *Chairman.*

VISITING-PHYSICIAN TO GIRARD COLLEGE, PHILADELPHIA.—The Board of Philadelphia City Trusts, at their meeting on Wednesday evening, February 12th, refused to accept the recommendation of the Committee on Household, *i.e.*, that of Dr. T. B. Reed to fill the position of visiting-physician to Girard College, made vacant by the death of Dr. I. B. Biddle, and elected John J. Reese, M.D., Prof. of Toxicology in the University of Pennsylvania, to the position.

EMMA PLATT VS. THE CONTRIBUTORS TO THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.—An action to recover for damages sustained, it was alleged, by improper food furnished to the plaintiff at the Hospital. The patient claimed, by her lawyer, before Judge Finletter, in Philadelphia, on Wednesday, Feb. 19th, that she was a nurse at the institution in question in 1877, that when she went there she was enjoying excellent health, and was competent to do all the work required of her, but that, in consequence of the food and milk furnished her, which she alleged was adulterated, her health suffered to a great extent, causing her to become dizzy, have cramps, a feeling of nausea, etc., and that, notwithstanding her complaints and protests, the same quality of food was furnished her upon several occasions, in consequence of which her injuries had proved to be of a permanent character, and had incapacitated her from further work of this character and from earning a livelihood. While the plaintiff's counsel, in opening the case to the jury, used the word "adulterated," he would not specify in what the adulteration consisted, but in the declaration filed, it was charged that the plaintiff's food had been poisoned, and the plaintiff, during her examination, testified, among other things, that tartar emetic had been put in her food, for the purpose of destroying, not her life, but her intellect. The testimony of the woman when put upon the stand was very flimsy, the only show of stability in her case being that the Hospital apothecary had examined some of the food furnished the patient at the time of her employment in the Hospital, and had told the woman that he thought it contained tartar emetic. At the time of the trial, however, this same apothecary stated that he was not at all sure of the accuracy of his tests. The general opinion was that the plaintiff was crazy. At the conclusion of the plaintiff's testimony the presiding judge ordered a non-suit to be entered against her, saying that an institution such as the above mentioned could become responsible only in three ways: 1st, if they compel or order their servants to commit a criminal act; 2d, if they knowingly permit a servant to do such an act; and 3d, if the act of

their servants produces injury, that act being the result of carelessness on the part of their servants in the performance of their duty. That the plaintiff's case belonged to the first and second class; the charge being that they themselves did it—did it, of course, by their servants—but through their hand and direction and knowledge; and, secondly, that they knowingly permitted the drug to be administered. That at the conclusion of her testimony there was no evidence that the plaintiff knew that she was being either wilfully or negligently poisoned by any one. That he did not see that a single particle of testimony had been brought forward to justify any of the allegations that the plaintiff had made, and that, of course, there was nothing to sustain her case. While the case was on trial there was a good deal of indignation felt by the friends of the Hospital at the attempt made to drag its management into disrepute.

DINNER OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS.—The Alumni Dinner will occur at Delmonico's, corner 26th Street and 5th Avenue, on this evening, Saturday, March 1st, at 6.30 o'clock.

DINNER OF THE ALUMNI ASSOCIATION OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.—The eighth annual dinner of the Alumni Association of the Medical Department of the University of the City of New York, took place at Delmonico's on the evening of February 20, 1879. The occasion was a very enjoyable one, and the festivities were continued to a late hour. There were about eighty guests present. Toasts were responded to as follows: "The University of the City of New York," Rev. Charles F. Deems, D.D.; "Our Alumni," Prof. John C. Draper, M.D., Class 1857; "Our Sister Colleges," Prof. Henry B. Sands, M.D., Prof. Wm. M. Polk, M.D.; "Our Public Charities," Hon. Isaac H. Bailey; "The Pulpit," Rev. John Cotton Smith, D.D.; "The Bar," Col. Granville P. Hawes; "The Press," Noah Brooks, Esq.

The following officers were elected for 1879: *For President*—Dr. D. B. St. John Roosa. *For Vice Presidents*—Drs. William A. Hammond, John R. Dickson, S. Fleet Speir, J. J. Peterson, J. W. S. Gouley, W. E. Ford. *The Secretary*, Dr. Fred. R. S. Drake, was elected last year for a term of three years. *For Treasurer*—Dr. C. Dixon Varley. *For Executive Committee*—Drs. Stephen J. Clark, F. Le Roy Satterlee, A. E. MacDonald, Edward L. Pardee, Andrew Otterson, R. A. Witthaus, W. C. Lutkins, L. Goldschmidt, Newton M. Shaffer, J. H. Hobart Burge, H. B. Conrad, R. A. Murray.

DR. JOHN BYRNE, of Brooklyn, describes and figures his new uterine repositior for inversion of the uterus in the December number of the *New York Medical Journal*.

YELLOW FEVER—ITS ORIGIN, PROPAGATION, NATURE, AND MORBID ANATOMY.

A LECTURE DELIVERED BY SPECIAL REQUEST BEFORE THE GRADUATING CLASS OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA.

By ALFRED STILLÉ, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE.

PART II.

GENTLEMEN:—The hypothesis of the origin of yellow fever in specific microscopic germs is a very old one, and the arguments in its favor and against it were summed up by La Roche, in his great work on yellow fever, as long ago as 1855. Ten years later an English writer assumed that the virus of this disease and all "primary zymotic poisons owe their origin to the development of the humbler and more minute, and therefore more subtle forms, of animal and vegetable life." The ground of the claim made by the microscopists whom I have named is that they have demonstrated what before them was only supposed to exist. But admitting the facts which they have brought to light, that the renal and the biliary ducts, and the blood of persons who have died of yellow fever, are filled with the organisms they describe, we shall await with interest the counter-proof that similar organisms are not found in malarial fever and other so-called "zymotic" diseases. Until then we cannot admit that they have demonstrated that any such condition as they describe is peculiar to yellow fever. To adduce the presence of these organisms in the biliary ducts as a cause of the jaundice in this disease is to overlook the capital fact that in yellow fever, so far from their being an accumulation of bile in that organ, it is singularly pale through the absence of blood from its vessels and of bile from its ducts, and that the characteristic jaundice of the disease is due to suppression of the secretion of bile, and not to its retention in the liver. In regard to the accumulation of fungoid spores in the tubules of the kidneys as a cause of the alleged "diminution or suppression of urine" which is said to be "such a common and fatal symptom of the disease," it must be remarked that this statement is not borne out by clinical observation, nor is it consistent with what we know of the effects of suppression of urine in other diseases. Renal obstruction occasions convulsion or deep stupor, a totally different condition from that which characterizes the ordinary mode of death from yellow fever. It is often a state of conscious resignation or of apathetic indifference, or of a cheerful, delirious revercy; and even when the coma is profound it is not so uninterruptedly, but often alternates with delirium. These are not the phenomena of uremia. While it is very certain that suppression of urine is generally a fatal sign, it is equally so that death in this disease constantly occurs independently of any such symptom, and while the urine is freely secreted. In certain epidemics a majority of fatal cases present this symptom, but in others it is not the uniform nor even the usual precursor of death. It follows, therefore, that neither uræmic symptoms nor suppression of urine, nor the assumed cause of their production, can be accepted as a sufficient explanation of the phe-

nomena of the disease. It should not be lost sight of that obstruction of the kidneys as a cause of suppression of the urine and of uræmic symptoms in this disease is a generally accepted pathological fact; but pathologists have hitherto recognized as a cause of the obstruction an infarction of the renal tubules, with desquamated epithelium, which they did not discern hypothetically, but demonstrated with the microscope.

YELLOW FEVER NON-CONTAGIOUS BUT INFECTIOUS.

Having thus sketched an outline of our knowledge of the origin, diffusion, and essential cause of yellow fever, there remains to be noticed the question of its contagiousness, *i. e.*, its propagation by something generated in and emanating from the body of the sick, and conveyed to the well by direct contact or indirect communication with them through any medium whatever. These are the essential conditions of contagion as we see it illustrated in the dissemination of small-pox, measles, scarlet fever, typhus and typhoid fevers. Yellow fever is not propagated in this manner. In a circular issued by the Surgeon-General of the U. S. Marine Hospital Service, in September last, it is stated that "yellow fever patients have been treated in the marine hospitals at St. Louis, Cairo, Louisville, and Cincinnati without communicating the disease, the simple precaution having been taken to disinfect the clothing and other effects immediately on receiving the patients. It is a well-known fact that the unacclimated attendants upon the yellow fever patients at the New York Quarantine do not contract the disease." And the Surgeon-General is justified in adding that "yellow fever is transported by *things*, and not by persons considered apart from their clothing." A similar judgment has been pronounced by all physicians residing in our yellow fever cities, whose professional rank entitles their judgment to the greatest weight. The late Dr. Nott, who spent nearly all of his professional life in Mobile, and whose competency in such a question no one will doubt, states his judgment thus: "Yellow fever is not generated in the human system, nor transmitted from one person to another in any way; its germ or poison is generated outside of the human system, and is taken into the system after the manner of the marsh malaria poison. But, unlike the latter, its germ is portable, and may be carried from one point to another, and thus propagated." And again he says: "Few of the old and experienced physicians of the yellow fever zone believe in the contagiousness of the disease, and their convictions are based upon facts coming under their observation. During thirty years' residence in Mobile my experience corresponded with theirs." The late Dr. Warren Stone, of New Orleans, who probably had more experience of yellow fever than any man who ever lived, stated emphatically the exact truth when he declared, "I am perfectly convinced, beyond all doubt or hesitation, that, personally, it is not contagious. I *know* that it is not." In this city, at various times during nearly a century, local epidemics of yellow fever have occurred from time to time, every one of which was distinctly traceable to vessels from infected ports. Many of the patients were received into our ordinary hospitals, and perhaps not always with due care to leave behind their infected clothing; and yet in no single instance has the disease attacked their attendants or the surrounding hospital patients. Similar illustrations without number might be cited to prove the absolute incommunicability of the disease from the sick to the well. It would be very instructive to contrast with these facts innumerable

others in which yellow fever was introduced into healthy ports by vessels on board of which not a single person had at any time during the voyage suffered from the disease, showing that, although not contagious, its cause is highly infectious.

This distinction is not a deduction from scientific principles, nor is it a convenient hypothesis; it is a plain lesson taught by plain facts, which, however, it required a modicum of common sense to interpret, seeing how difficult it is to distinguish between the agency of a ship and its crew, and between people and their clothing. But the truth has been made plain by the results of quarantine already adverted to. When the ship and its cargo, its crew and its passengers, have been purified of the perilous stuff they brought with them from yellow fever ports, they have become harmless in our docks and our houses.

These plain and well-established lessons were heeded in the summer of 1878 at the port of New Orleans. Infected persons and goods found their way into the city, and in due time the germs which they introduced multiplied and spread the disease throughout the city. The panic-stricken people sought refuge in flight, and they, with their infected goods, spread the infection along the line of their exodus, eastward and northward to the Ohio River, and beyond it, until nearly 15,000 persons were sacrificed to the incompetency or connivance of those officials whose duty it was to protect the country against the entrance of the destroyer. And yet in all this desolation we do not learn that anything has occurred to prove the personal contagiousness of yellow fever. As a single illustration of the mode in which it spread, I may cite the case of Grenada, Miss., a town of 2,500 inhabitants, of whom 1,040 were attacked with the fever, and 326, or more than 30 per cent., died. The fever first broke out in a family of which the mother had been to the railroad depot to see her daughter off to a neighboring town. The train was from New Orleans, where the fever was then raging, and the mother, it is thought, occupied a seat in the railroad car alongside of her daughter for about twenty minutes, while the New Orleans passengers were taking breakfast.

THE RAPIDITY OF THE DIFFUSION OF THE YELLOW FEVER POISON.

In the history of the late epidemic, as of many previous ones, there is much to illustrate the rapidity and extent of diffusion of the yellow fever poison. These qualities seemed to lend a strong probability to the zymotic hypothesis of the disease, for they seem to resemble those of fermentations as it occurs in certain liquids and in bread dough. "A little leaven leaveneth the whole lump," and a single infected bale of goods or garment may infect a whole city. The disease was introduced into New Orleans as early as May 23, 1878, and before July 12th, thirty or forty deaths from it had occurred, the reports of which were at the time suppressed. It broke out in the form of a series of groups of cases, each being connected with some other by personal association or by exposure in the same locality, and from these separate foci the conflagration spread over the whole city. Thence it was carried "in the clothing or about the persons of people going from the infected districts. In other instances, it was conveyed in such fomites as cotton bagging, or goods of some description, or bedding and blankets" (Dr. Bemiss's Report).

A LOW TEMPERATURE FATAL TO THE PROGRESS OF THE DISEASE.

Finally, as a high temperature is necessary to develop the disease from its germs, so a low temperature suspends or destroys their activity and arrests the progress of yellow fever epidemics. You must have noticed that, on the first occurrence of frost, the spread of the recent epidemic abruptly ceased, first upon the northern limits of the area within which it had prevailed, and rapidly thereafter at points more and more southwardly, until at last it ceased in New Orleans. But experience has shown that in this way it is not always absolutely killed, that its activity may be only suspended, and that where it has prevailed in the autumn it will perhaps reappear the following year at the same season, if the weather favors its revival. In that case it usually assumes a milder type, and may even reappear once more with lessened virulence the succeeding year, or until it fades entirely away. Again, a transient period of cold weather does not always put an end to an epidemic of yellow fever; if the temperature rises again, the disease may break out anew. But it should be remembered that, even in our southern seaboard cities, the subsidence of an epidemic is not always delayed until frost: and in Cuba, where frost is unknown, yellow fever subsides, like other epidemics elsewhere, for want of food to feed on, since all who are susceptible of having the disease have already paid their tribute to it.

THE PATHOLOGY OF YELLOW FEVER.

Having thus sketched the conditions under which yellow fever arises and prevails, we might proceed to consider the symptoms which characterize it. To render them intelligible, however, we should first learn what alterations of function and structure the disease occasions in the organs that inhibit its distinctive symptoms. I shall attempt nothing further on the present occasion. The symptoms point directly to the blood, the stomach, and the kidneys as organs which are most deranged in their structure, and so, in point of fact, they are. When venesection was practised in the treatment of yellow fever, it was observed that the coagulability of the blood was diminished in proportion to the gravity of the attack, and that the serum was yellowish or reddish yellow. It has shown more recently that its natural alkalinity has been replaced by acidity; that it generally contains a notable proportion of urea, especially in the advanced stages of the disease and after death; indeed, according to one observer, "it is seventy times more abundant in the yellow fever blood than in normal, healthy blood" (Jones). According to the same author, Dr. Joseph Jones, cases attended with suppression of urine are "characterized chiefly by great diminution of the fibrin, which, in some cases, he found to be not one-hundredth of the usual amount; and by the abnormal amounts of urea and ammonia, and other sulphates, phosphates, and extractive matters." He was unable, "even after the most diligent search with the highest magnifying powers, to discover in the fresh blood of yellow fever patients any living animalculæ, or vegetable cells, or sporules, or pigment-granules." The latter statement should be weighed against that of Drs. Richardson and White, who detected an obstruction of the kidneys by fungoid spores. As to the microscopical appearances of the blood itself, there is no doubt that a large proportion of the red corpuscles is found to be loosely scattered, instead of forming rouleaus, and that many are also disintegrated, the degree of

these changes varying with the malignity of the disease.

THE CAUSE OF BLACK VOMIT.

Identical, but more complete changes are found in the blood that constitutes the black vomit. It is not always black at first. It is due to two causes: the liquefaction or disorganization of the blood, and the inflamed and softened condition of the gastro-mucous membrane. Vomiting in this disease is at first bloodless, and is due to inflammation of the stomach. As the liver secretes but little bile, the rejected fluid is watery and mucous, and has at first an alkaline reaction. But later it becomes acid, and is shown, by appropriate tests, to contain muriatic acid. Its acidity is so great that it creates an acrid, burning sensation in the throat and stomach, and continues to do so even after basins of it have been vomited. When allowed to settle, the vomit separates into two portions, of which the lower is grumous and almost black, and the upper is as clear as pure water. On microscopical examination this deposit is found to consist of loose and disintegrated red-blood cells. "No animalcule are discoverable in either fresh or putrescent black vomit; but, as it decomposes, certain fungi are disclosed, which are most frequently, if not always, developed outside of the body during fermentation" (Dr. M. Michel). Urea is said to have been found in the contents of the stomach. The condition of the stomach is inflammatory, with a greater or less tendency to softening of its mucous coat. Sometimes it is of a deep brown color from the blood accumulated in its veins, and altered by the acid contents of the organ. When the black vomit has been copious, the vessels of the stomach are empty, and the mucous membrane pale. Specks or spots formed by ecchymoses or effused blood are often observed. The organ usually contains more or less of the "black vomit," varying in quantity from three or four ounces to a pint. It deserves notice that the inflammation of the stomach is pretty equally diffused throughout its mucous coat, and that there is no evidence that its glandular apparatus is specially involved. In this respect the condition of the organ contrasts remarkably with its state in remittent fever, in which disease the mucous glands of the organ at its pyloric end are greatly enlarged.

THE YELLOW FEVER LIVER.

Not less dissimilar is the liver in yellow fever from that which occurs in remittent fever. In the latter the organ is enlarged, distended with blood and with bile, and presents a characteristic dark bronze color; but in yellow fever the organ is pale, and appears to be devoid of even its normal proportions of bile and blood. This peculiar appearance was first described by Louis, in his account of the epidemic at Gibraltar in 1828, as "being sometimes of the color of fresh butter, sometimes of a straw color, sometimes of the color of coffee and milk, sometimes of a yellowish-green, mustard, or orange color." The change may probably be ascribed to a drainage of the blood of the liver into the stomach; it is in nowise a fatty degeneration, for in that condition the cohesion of the liver is softened, whereas in this it is increased or unaffected. To whatever cause it may be due, it is certainly peculiar to yellow fever. The gall-bladder is usually empty, or contains only a little viscid bile. These facts harmonize with the presence of an excessive quantity of biliary coloring matter in the blood, the urine, the skin and other tissues.

The kidneys do not present in their general aspect

any characteristic appearances. Like the other tissues, they are yellow, but they are neither enlarged nor softened. On microscopical examination they present only the ordinary lesions of desquamative nephritis in their tubular portions; that is to say, the tubules are distended with epithelium, and more or less with albuminous casts. But this intarction of the organs is sufficient to account, in part at least, for the albuminous quality of the urine in the disease, and for the presence of so large a proportion of urea in the blood.

No other lesions found after death in this disease appear to be related to its symptoms. In the cerebro-spinal centres no alteration is observed except, perhaps, nervous engorgement. The spleen is not enlarged, nor is it softened out of proportion to the other tissues. Half a century ago Louis described the heart as being flabby with diminished cohesion of its muscular tissue. Riddell and others long ago laid much stress upon the quite constant molecular degeneration, and quite recently Dr. Joseph Jones claims to have determined, both by chemical analysis and microscopical examination, that the heart undergoes acute fatty degeneration in yellow fever. However this may be, it is very certain that during life no symptoms point to any special debility of the heart, such as would be occasioned by such a lesion. Indeed, "it has been known to preserve an apparently normal state, even coincidentally with other portentous symptoms, and the pulsation of the heart may continue some time after all the respiratory movements have ceased." This clinical fact is of greater weight in establishing the essential integrity of the heart-muscle in this disease than are any number of microscopical observations that go to demonstrate the degeneration of its tissue in proving the organ to be functionally incapable.

In conclusion, gentlemen, I have endeavored to impress upon you the following propositions:

1. That yellow fever originates nowhere but in the West Indies.
2. That its morbid poison is conveyed elsewhere in ships and fomites.
3. That, wherever conveyed, a high temperature is essential to its propagation.
4. That a strict quarantine is always efficient in preventing its dissemination.
5. That it is not contagious.
6. That its essential cause cannot be isolated or defined, but must be assumed to be a specific poison.
7. That this poison in the system acts primarily in two ways, by disintegrating the blood and inflaming the stomach; and that, secondarily, it tends to impair the eliminating function of the kidneys.

A NOVEL METHOD OF SMUGGLING. The tricks of the smuggler are certainly curious. A wagoner stopped, a short time ago, before the custom house of Neuville-aux-Fontes, a town in the north of France, and asked for a permit to enter the town. When the wagon was inspected, the bodies of two dead horses, far advanced in putrefaction and emitting a horrible odor, were found in it. The very strangeness of the loud excited suspicion, and a closer examination revealed the fact that the intestines of the animals had been removed and replaced by tobacco. The quantity seized weighed 385 pounds. The smokers of that town have reason to congratulate themselves on their escape.

Original Communications.

THE TREATMENT OF HEMORRHAGE IN ABORTION.

By W. T. LUSK, M.D.,

PROFESSOR OF OBSTETRICS, AND DISEASES OF WOMEN AND CHILDREN
IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE.

[Read before the Medical Society of the State of New York, February 5, 1879.]

I AM well aware that the subject I have selected possesses none of the charms of novelty. The ordinary necessities of practice make it one in which each individual member of this Society has had a large and varied experience. Nevertheless, the question involved in the title of this paper is never raised for discussion among professional men without bringing into strong relief the divergent opinions regarding the best methods of procedure. The directions contained in text-books are for the most part vague and unsatisfactory. Thus it comes to pass that the young practitioner, who finds himself for the first time brought face to face with a hemorrhage associated with abortion, is not a little embarrassed when he asks himself whether in the special case he is simply to use the vaginal douche, or whether he shall tampon, or whether he shall at once proceed to extraction of the ovum. Nor is this feeling of perplexity confined to the tyro alone. Hardly a month goes by that some poor exsanguined creature is not sent half moribund to my uterine ward in the Bellevue Hospital, a victim of indecision and halting practice on the part oftentimes of the senior members of our craft.

With faulty management, death from abortion is by no means an infrequent occurrence. The deaths from this cause, reported between the years 1867 to 1875 inclusive, to the Bureau of Vital Statistics in New York, were one hundred and ninety-seven, a number which falls in all probability considerably short of the truth by reason of the many circumstances which precisely in this condition tempt to concealment. The total number of deaths during the same period from metria were, according to the reports rendered, 1,947. Hegar reckoned one abortion to every 8 to 10 full-time deliveries,* a proportion, if correct, which would seem to show a mortality from abortion hardly second to that of puerperal fever itself. In addition to fatal cases, the large amount of uterine disease traceable to bad management at the time of abortion contributes still further to the grave responsibility which rests upon the physician.

And yet, excluding cases of criminal malpractice, and wilful neglect on the part of the patient, an abortion, unless it occurs as a complication to otherwise dangerous diseases, ought to be free from peril. I have made the exceptions advisedly. M. Tardieu found that in 116 cases of criminal abortion of which he was able to ascertain the termination, 60 died.† A few years ago a lady laughingly told me that she had made the trip from Paris to Havre, on her way to this country, the day following the occurrence of an abortion, in spite of the protestations and entreaties of her physician. Since then she has died of peritonitis consequent upon a similar act of imprudence.

In hospital practice where patients are under direct

control, deaths rarely if ever occur. Dr. Johnston reports that during his seven years' mastership of the Rotunda Hospital, there were 234 cases of abortion. One of these died, but it was from mitral disease of the heart. In the history books of the Bellevue Hospital I find a similar clean record. That like favorable results have been obtained in other hospitals, and by many physicians in private practice, I do not doubt. Indeed, it is astonishing how large a proportion of cases do well under rest in bed, and careful nursing without the intervention of the physician. A lady belonging to my clientèle, aborted at the fourth month during the past summer, while at the sea-side. The physician of the place called daily, but never once came near the bedside of the patient. She lost a great deal of blood, but as she happened to be a strong woman, and as the entire ovum was expelled, she made a rapid recovery.

Now it seems to me such cases are calculated to mislead and to encourage a *laissez faire* practice in every way to be deprecated. As I look over the records of Bellevue Hospital I find a number of patients treated a few years ago with rest, ergot, and the vaginal douche. They all recovered, it is true, but many with long histories of repeated hemorrhages, fetid discharges, and local inflammations. They were doubtless discharged finally with subinvolution of the uterus, and uterine and cervical catarrh; to add to the already overgrown contingent of helpless broken-down women who seek relief in our public dispensaries. I have nothing but words of praise and honor for those who have contributed so much in the past ten years to perfect the practice of gynecology. I regret, however, that the flattering interest their labors have excited, have tended to weaken the interest in the sister department of obstetrics. While our young men seem all desirous to make a specialty of the diseases of women, it is hard to obtain a hearing for the statement of the very trite fact that it is faulty midwifery which gives to gynecology nearly all its importance.

During the past five years I have left very few cases of abortion to the unaided efforts of nature. I not only never have had occasion to regret intelligent interference, but contrasting my later cases with those in which the Fabian policy was adopted, the favorable results are such as to impel me to missionary efforts in behalf of bold and prompt procedure. I do not propose to take up the time of the Society with the relation of illustrative cases. I should only repeat what has been frequently paralleled in the experience of others. I shall simply endeavor to formulate the rules of practice, which, in the varied contingencies presented to us, have seemed to me satisfactory.

As it is practically desirable to make some distinction between interruptions of pregnancy taking place in the earlier and later months previous to the time when the child becomes viable, I shall use the term abortion to designate the discharge of the ovum in the first three months, and apply the expression "immature delivery" to the completion of labor from the fourth to seventh month inclusive.

THE TREATMENT OF INEVITABLE ABORTION.

In the first two months little treatment besides rest in bed for a few days is ordinarily required. In the exceptional cases the treatment does not differ from that in the hemorrhages of the non-pregnant uterus.* In the third month we distinguished:

I. Cases in which the ovum is thrown off entire.

* Hegar, Beiträge zur Pathologie des Eies, Monat Schrift, für Geb.-Kunde, Bd. XXI., Supplement-Heft, S. 35.

† Vide T. Gallard, De l'Avortement au point de vue Medico-légal, p. 45.

* In the discussion following the reading of this paper Dr. Barker drew my attention to the occasional severity of hemorrhages in the first two months of pregnancy.

tampon is made is a matter of indifference, provided only it fills the vagina to its utmost capacity. In cases of urgent need, a soft towel, handkerchiefs, strips of cotton cloths, dampened cotton, wool and the like, may be seized upon to meet a temporary emergency. The time-honored sponge, on account of its porosity, is least deserving of favor. When, however, the physician proposes to leave his patient for a number of hours, the mere hasty filling of the vagina through the vulva will not suffice. On the contrary, the highest degree of safety can only be secured by the closest observance of the rules of art.

The first essential of a good tampon is, that it be carefully packed around the cervix uteri, and fill out the more dilatatable upper portion of the vagina. This can be accomplished only by the aid of a speculum. The method I usually employ is one, the credit of which, so far as the general features are concerned, I believe belongs to Dr. Marion Sims. It consists in soaking cotton-wool in carbolized water, and then, after pressing out any excess of fluid, in forming from the carbolized cotton a number of flattened disks about the size of the trade dollar. The patient is then placed in the latero-prone position, and the perineum retracted by a Sims' speculum. The dampened cotton disks are introduced by dressing-forceps, and under the guidance of the eye are packed first around the vaginal portion, then over the os, and thence the vagina is filled in from above downward, until the narrow portion above the vestibule is reached. No other plan of tampon with which I am acquainted can compare in solidity and effectiveness with this. Its removal is accomplished by the detachment with two fingers of a portion at a time. This part of the procedure is moderately painful. Many methods have been suggested to overcome, in the removal, the necessity of introducing the fingers into the vagina. A very ingenious one consists in attaching the cotton to a piece of twine, so as to form a kite-tail, which can be withdrawn by simply making tractions upon the extremity of the string left hanging outside the vulva. Prof. I. E. Taylor uses a roller bandage. It is efficient, and, like the kite-tail described, can be easily removed.

Before the introduction of the tampon the vagina should be thoroughly washed out. No tampon should be allowed to remain in the vagina much over twelve hours. Immediately after withdrawing the tampon, before proceeding to the examination of the uterus, the vagina should be cleansed by an injection of tepid carbolized water (gr. xxx. ad Oj.). Often, after the removal of the tampon, the ovum is found in the upper portion of the vagina, or filling up the cervix. If this is not the case, and the cervix is not dilated, so that manual extraction may easily be performed, the tampon should be reintroduced.

It is customary from the outset to sustain the action of the tampon by the administration of ergot, either in the form of the fluid extract (thirty drops every three to four hours), or of a solution of ergotine given hypodermically. (Ergotine, gr. xij. glycerine, ʒi., ten minims twice in the twenty-four hours.) In women with abundant adipose tissue, the injection should be made into the subcutaneous tissues of the lower abdomen. In others, the outer surface of the thigh should be selected.

If the patient is collapsed from loss of blood, after tamponing, opiates, tea, and alcoholic stimulants should be administered; the latter in small, but frequently repeated quantities, until the cerebral anæmia is relieved, and the capillary circulation restored.

If after its removal the cervix is found not to be

dilated, the tampon may be reintroduced and left *in situ* for another period of twelve hours. The employment of the tampon is not, however, to be recommended for a period much exceeding twenty-four hours. Its continued use is apt to irritate the vagina. In spite of carbolic acid it acquires an offensive odor. It generates septic matters which, in the long run, creep upward through the cervix into the uterine cavity, and produce decomposition of the ovum. I prefer, therefore, in cases of undilated cervix, after twenty-four hours of vaginal tamponing, to resort to sponge-tents. The tent should be long enough to pass well up through the os internum. After six to twelve hours the tent should be removed, and, after a preliminary vaginal douche, manual extraction be proceeded with in accordance with the rules already given.

In manual delivery it is desirable to remove the decidua as well as the ovum. When the cervix is patent this is easy, as the decidua is then detached from the uterine walls. When the cervix is unchanged the detachment is usually incomplete. In such cases it is advisable, therefore, to try first the tampon before the sponge-tent, as the former stimulates the uterus to contract, and promotes the separation of the decidua, even when it fails to secure the discharge of the ovum.

Inside the uterine cavity ovum-forceps should be used with great caution. I have discarded them altogether. In the first place they are dangerous. In the second place they are unnecessary. When, however, the retained portions of ovum have left for the most part the uterine cavity, and occupy the cervical canal, the delivery may at times be advantageously hastened by placing the patient upon her side, and, with the cervix well brought into view by a Sims' speculum, applying the ovum-forceps, under the guidance of the eye, within the cervix to the sides of the placenta (Skene). But great care requires to be exercised not to break away the fragile structures, and leave material portions behind.

Under like circumstances Hoening* recommended a modification of Crede's method for expression of the placenta. With the patient lying upon the back, the operator, according to Hoening, should seek to compress the body of the uterus between the left hand, laid above the symphysis pubis, and two fingers of the right hand, introduced into the vagina. The measure is only practicable when the ovum has, to a great extent, passed from the uterine cavity. As it is somewhat painful, and requires, for success, lax abdominal parietes, it possesses a limited range of applicability.

Treatment of Neglected Abortion.—When, following abortion, the uterus has once been completely evacuated, hemorrhage ceases. A slight lochial discharge persists for a few days during the period in which the uterine portion of the decidua vera completes its period of repair. If, therefore, a patient comes to us two to three weeks after the supposed conclusion of an abortion, with the story of recurrent hemorrhages taking place in the rule whenever she leaves her bed and assumes the upright position, it may be assumed, with an approach to certainty, that portions of the ovum still remain within the uterus. Oftentimes a fetid discharge points to the fact that decomposition has been set up. The absorption of septic materials may furthermore become the source of chills, of fever, and of great uterine tenderness. In most cases, with rest in bed, the contents are discharged by suppuration,

* HOENING, *Scarzon's Beiträge*, Bd. vii., S. 213.

and recovery ultimately takes place, but only after a slow protracted convalescence, during which pelvic cellulitis and pelvic peritonitis occur as not uncommon complications. Hemorrhage, peritonitis, and septicæmia may, however, bring the case to a fatal issue. The removal of the retained placenta and membranes is therefore indicated not only as a measure calculated to promote recovery, but to avert possible danger to life.

With regard to the operation for removal, the rules already given are applicable. The following peculiarities should, however, be borne in mind. In case the retained portions are undecomposed the cervix is usually found closed, and requires preliminary dilatation with the sponge-tent. When decomposition has once set in, the os internum will, in the rule, allow the finger to pass into the uterus.* When a decomposed ovum is removed by the finger, a chill and a septic fever, which rapidly exhausts itself, however, is apt to follow in the course of a few hours. This chill and fever result from the slight traumatic injuries inflicted by the finger upon the uterine walls, whereby the capillaries and lymphatics become opened up to the action of the septic poisons. The fever ends in a short time because the reservoir of supply is removed with the *débris* of the ovum. If the uterine cavity, after the operation, is carefully washed out with carbolized water, the septic fever is often averted. The beneficial results following the complete emptying of the uterus in these cases are so decided, that of late years I have not allowed myself to be deterred from proceeding actively, even when perimetritis and parametritis in not too acute a form already existed. In practice, multitudes of examples show that the products of inflammation situated in the pelvis, do not absorb so long as putrid materials are generated in the uterine cavity.

The removal of a fibrinous polypus, owing to its smoothness and the small size of the pedicle, is often a Sisyphus task. The separation can only be successfully accomplished when the palmar surface of the index finger presses from above upon the point of attachment. This necessitates a choice of hands. Thus, when the polypus is situated to the right, the right index finger should be employed; and the left index finger when the polypus is situated to the left. After the detachment is complete it is necessary to press the polypoid body firmly against the uterine walls and proceed with its withdrawal slowly. If, as sometimes happens, the polypus slips from under the finger, it is necessary to pass the finger again to the fundus of the uterus, and repeat the attempt. Small portions, not larger than a pea, can be washed out by the uterine douche. When the polypus is attached near the os internum, the latter will be found patulous, but, when it is well up in the body of the uterus, dilatation with sponge-tents is a frequent prerequisite to removal.

A good deal of testimony has been offered of late, by Skene, Spiegelberg, Mundé, Boeters, and others, in favor of the use of the curette for the removal of retained portions of ovum. To whom, exactly, the honor of this method belongs it is difficult to say. Accidentally, I read in a record book of Bellevue Hospital, a few days ago, an account of the operation performed by Dr. Fordyce Barker in 1870. With the curette the dangers from dilating the os and manipulating the uterine cavity are avoided. For myself, however, I confess I never feel quite safe until my index finger

has made the complete tour of the uterine cavity. Still, the method has its advantages in cases where the removal of bodies retained within the uterus is complicated by the existence of extensive peri- and parametritis.

The Treatment of Immature Deliveries (fourth to seventh month).—Distinctive of immature deliveries are: painful periodic uterine contractions, which can be recognized by the hand applied above the symphysis pubis; rupture of the membranes, and discharge of the fetus; the complete formation of the placenta and umbilical cord; while in abortion the uterine contractions are obscure, the placenta rudimentary, and the ovum is frequently expelled entire. In the treatment of immature delivery the tampon may usually be discarded. After rupture of the membranes and expulsion of the fetus, the hemorrhage should be controlled by grasping the fundus of the uterus in the hand through the abdomen and compressing the uterine walls firmly together.

The passage of the fetus opens the uterus so as to allow, in the fourth and fifth month, the introduction of two fingers; in the sixth and seventh month, that of the half-hand. In case compression of the uterus does not arrest the hemorrhage and expel the placenta, the cord should be carefully followed to its insertion, to determine the side upon which the implantation exists. If the placenta is implanted upon the right side, two or four fingers of the right hand, according to the degree of cervical dilatation, should be passed up along the left side of the uterus, across the fundus to the placental site. The detachment should be effected with the tips of the fingers, and the placenta pressed downward as the fingers descend along the right side of the uterus. The left hand should be employed, in the reverse direction, when the placenta is situated to the right.

In conclusion, the following summary of the views which have been expressed is respectfully offered:

1. In the first two months an abortion needs no special treatment. The hemorrhages of early date are amenable to the same principles of treatment as those from the non-pregnant uterus.

2. In the third month no treatment is required when the ovum is expelled with intact membranes.

When the membranes rupture previous to expulsion, and hemorrhage takes place, immediate removal should be attempted, provided the cervix be sufficiently dilated to admit the index finger. When the cervix is closed, the tampon should be tried for twenty-four hours. If the tampon proves ineffective, the cervix should then be dilated with a sponge-tent, and the ovum removed with the finger. The finger should pass up along the side of the uterus, across the fundus, and complete the circuit of the uterine cavity.

3. In cases of neglected abortion, retained portions should be removed by the finger or the curette. When the ovum is decomposed, no dilatation of the os is usually necessary. When the ovum is fresh, the preliminary use of sponge-tents is usually demanded if manual delivery is resorted to.

4. Fibrinous polypi, when situated near the os internum—a rare occurrence, indeed—arrest the involution of the lower portion of the uterus. The os is therefore open in the rule, and permits the passage of the finger. When the polypus is attached to the fundus, the cervix is usually closed. Small, smooth, slippery bodies, like fibrinous polypi, are rarely to be detached, unless the finger operates from above, so that the choice of hands depends on the side to which the polypus is attached.

* HUBER: *Compendium der Geb. Operationen*, Leipzig, 1874, S. 12.
To this excellent work I acknowledge my indebtedness for many hints and suggestions of extreme practical value.

5. In immature deliveries hemorrhage can usually be controlled without the tampon, by compression of the uterus, and, in cases of delay, by the manual extraction of the placenta.

Reports of Hospitals.

CHARITY HOSPITAL.

SERVICE OF DR. F. N. OTIS.

PROBABLE SYPHILITIC INFECTION WITHOUT THE CHARACTERISTIC INDURATION ABOUT THE INITIAL LESION.

THE patient gave the following history: About five weeks previous he had connection (for the first time in a number of months). This was followed by a slight abrasion on the penis, of which he took very little notice. Two weeks afterwards he again had connection, and a few days later the present sore made its appearance, and the glands in the groin became enlarged. Upon examination there was found upon the under surface of the penis, near the frenum, a sore somewhat circular in outline and considerably more than half an inch in diameter. This had recently been cauterized by the house-surgeon, and was now covered by a crust. It was stated, however, that the sore presented very much the same appearance before cauterization, its surface being well scabbed over. Dr. Otis remarked that if this had been a chancreoid there would probably have been a considerable destruction of tissue, while here there was little, if any such loss; although the activity of the inflammatory process in chancreoid varied greatly in different cases, and was sometimes of a very low grade. On the other hand, there was nothing whatever of the characteristic induration ordinarily associated with a true syphilitic sore, usually occurring in from ten days to three weeks after exposure. Still it would not do to judge from this fact that the presenting lesion here was not a syphilitic one. Although there was no induration, the glands of the left groin were found to be enlarged, insensitive, indurated—in other words, typical of syphilitic infection. This is the condition which Ricord has called "the venereal period." No gland enlargements were discovered at other points, and no trace of any eruptive trouble was present.

The chief points of interest about the case were the early affection of the glands of connection, and the difficulty of explaining this glandular induration without, apparently, any induration being previously associated with the initial lesion. Dr. Otis accounted for both these points on the supposition that in this particular instance, owing to certain peculiar circum-

stances, the syphilitic virus had reached the lymphatic system of the patient in an unusually short space of time. It was thought that the implication of the glands of connection would take place in a longer or shorter period in any given case, according as the distance from the initial sore to the underlying lymphatic vessels of the part was greater or less. It had been proved by anatomists that the lymphatics approach very near the surface in the vicinity of the *frenum preputii*, being just underneath the epithelium, and the occurrence of the sore in this situation here would satisfactorily explain the promptness of the enlargement of the inguinal glands, as well as the absence of induration about the initial lesion. The reason why the latter had not become indurated was because, on account of its position, there had not been sufficient time for an accumulation of cells at this point before the lymphatic vessels of the part had been reached by the syphilitic infection. Ordinarily this took place in from two to three weeks, and Ricord used to say that, if a sore had not become indurated within three weeks after exposure, it would never become so. This was certainly true as a general rule, although in very rare instances induration had been known to occur after a longer period than this. One case was on record in which it was said to have occurred seventy days after exposure.

In support of the above idea Dr. Otis mentioned the case of a very noted southern surgeon who, while performing some operation upon a syphilitic patient, received a slight puncture in the end of his finger by a spicula of bone. Within twenty-four hours there was a line of swelling and slight redness extending up the arm. The glands of the axilla at once became enlarged and indurated. Then followed a well-marked general roseolous eruption, and the other ordinary manifestations of secondary syphilis; and still later tertiary symptoms appeared. At no time was there any induration about the initial lesion upon the finger, and the only reasonable explanation of the whole course of the phenomena in this instructive case was that the syphilitic virus had been introduced at once into the lymphatic system, without any preliminary interval, as is ordinarily the case. It would be interesting to watch the future of the present patient in order to see whether or not a correct view of its true character had been taken.

PHIMOSIS FROM PROBABLE CHANCRE.

The patient had had connection seven weeks before, and this was followed by a sore which he said looked like a simple raw and moist surface. Five weeks later, while he was drinking very hard, phimosis came on, and had continued up to the present. When admitted to the hospital, four days previous, the penis was greatly swollen and the redness of the surface extended almost to the pubes. The organ was now much reduced in size, and the redness was confined to the region near the glans; but there was still a considerable purulent discharge. The house-surgeon had been making applications of a solution of nitrate of silver, and, in consequence of the marked improvement that had taken place, had refrained from cutting.

Dr. Otis remarked that phimosis might depend upon either chancre, chancreoid, gonorrhœa, or balanitis (inflammation of semi-mucous membrane covering the glans penis). On examination it was found that the inguinal glands on one side were enlarged and indurated, and although their condition was not so characteristic of syphilis as those in the preceding patient, it was sufficiently marked to render it, in connection

with the history of the sore, probable that the man had an infecting sore upon his penis. No eruption or glandular enlargements in the cervical or epitrochlear regions, however, could as yet be detected.

In all cases where chancroid was present or suspected, it was best to avoid a cutting operation if possible, on account of the danger of the raw surfaces becoming inoculated with the chancroidal virus; and in view of the improvement that had already taken place, Dr. Otis thought it was not necessary to operate here; at least not unless some more urgent symptoms should arise. As to the treatment, he believed that it should be very simple. The patient should have perfect rest in bed, and all sources of irritation be kept away from the affected parts. Locally the two indications were simply to keep the latter perfectly clean and to apply some efficient local stimulant and disinfectant. For this purpose carbolic acid, of not greater strength than forty drops to the ounce, would probably be preferable.

OBSCURE TERTIARY SYPHILIS.

This was the case of a young girl, to whom Dr. Otis's attention was called about three weeks previously. At that time patient lay with her knees drawn up, and intolerant of the slightest pressure over the left side of the abdomen, or even touch of the fingers; some febrile excitement; pain was complained of as most severe over a space of three inches square to the left of the umbilicus. Examination under ether revealed a tumor about the size of the closed fist, solid, fixed, and irregular, over the course of the common iliac artery. Auscultation gave no abnormal sounds, no thrill or other evidence of aneurismal trouble, which was at first suggested by the location of the tumor in relation to the iliac and mesenteric arteries. After a few days a small, soft tumor was discovered over the spine at the junction of the lumbar with the dorsal vertebrae; this was about two inches in diameter, elevated about half an inch, slightly tender, obscurely fluctuating, and at first thought to be connected with the deeper parts. A careful examination proved it to be superficial and movable. There was no clear history of syphilis, but an account of local venereal sores several years previously; and the patient was then suffering from chancroid of the vulva. She was at once put upon iodide of potassium, with small doses of the biniodide of mercury. The iodide was gradually increased to ʒj. three times daily, well diluted. This was well borne, and under its use the pain subsided; the tumor in the iliac region was free from tenderness, and had decreased fully one-third in size, and that over the spine was one-half less in size, painless and boggy. Dr. Otis then remarked that not unfrequently in cases of obscure tumors, where there was no reliable evidence of antecedent syphilis, the touchstone of treatment cleared up the diagnosis in a prompt and satisfactory manner, as in the present instance, where the suspicious tumors were thus proven to be syphilitic gummata. In addition to the local effects of the specific treatment, the general health of the patient had also improved in a marked degree.

HYDROA FROM IODIDE OF POTASSIUM.

In a female patient, who had been suffering from syphilitic rupea and other constitutional trouble, and had been taking iodide of potassium freely for their relief, there had suddenly broken out upon the face, arms, and other parts of the body, the remarkable pustular eruption known as hydroa, which in occasional rare instances becomes developed during a prolonged course of this remedy. On first appearance the pus-

tules were more or less circular in outline (some of them being umbilicated); while some bore considerable resemblance to the blebs of pemphigus. As soon as the eruption was discovered, the iodide of potassium had been suspended altogether, and cod-liver oil and iron substituted for it; and the patient at once began to improve. At the time she was seen the pustules had dried, and the eruption presented merely the appearance of thick crusts scattered over the surface that had been affected.

Dr. Otis stated, in connection with this case, that during the course of syphilis, and especially in the later stages of the disease, cachectic conditions were sometimes developed under the persevering use of specific remedies, and apparently as a consequence of their action; it was then advisable to drop them altogether, at least for a time, and to administer such agents as cod-liver oil and iron in their place. It was not unfrequently the case that these seemed to have a beneficial effect not only upon the general condition, but also upon the syphilitic troubles; when, however, the specific developments advanced, it became necessary to return to the former remedies. In the present case, Dr. Otis said, he would not hesitate to resume the iodide of potassium if any aggravation of syphilitic manifestations should be noted; because, if it gave rise to any difficulty, the trouble could be easily controlled, as had been done in this instance. Thus far, however (a week from the cessation of the iodide of potassium and the mercurial fumigations which she was taking), the patient had not only improved in general health, but extensive superficial ulcerations of the limbs had quite healed.

DOUBLE SYPHILITIC IRITIS.

In the female venereal ward there was also a patient suffering from double iritis, in connection with a very bright and well-marked syphilitic roseola, associated with a characteristic enlargement of the post-cervical glands. In regard to the diagnosis here, Dr. Otis remarked that when in any case we found painless enlargement and induration of the inguinal glands following a suspicious sore about the genitals, the probabilities were that the patient was affected with syphilis, and that when a little later there followed a roseolous or papular eruption, accompanied by enlargement and induration of the post-cervical and other distant glands, there was no reasonable room for doubt about the matter; but that when, in addition to the above signs, there developed an iritis, the diagnosis was absolutely certain.

He considered it of great importance to recognize the presence of iritis as early as possible, so as to prevent the formation of inflammatory adhesions. When these had occurred, the fact was indicated by the irregular outline of the pupil, due to a certain amount of fixation of the iris on account of their presence. The recognized way to prevent such adhesions, as well as to break them up when recent, was to dilate the pupil fully by means of atropia, and keep it in this dilated condition until the inflammation was subdued. When these adhesions had become very firm, atropia was of no use for this purpose, and the only method of securing the patient's vision in the future was by the performance of iridectomy.

This case was an exception to ordinary syphilitic iritis, from the fact that it was double instead of single, and there was also a degree of photophobia, as well as of conjunctivitis, which is not always present. The action of mercury was of especial value in such cases, not only aiding in a solution of the adhesions, as

well as in their prevention, but in allaying the characteristic supra-orbital pain, which, like that of all syphilitic neuroses, was chiefly nocturnal.

ABNORMALLY CONTRACTED MEATUS URINARIUS, WITH PROBABLE STRICTURE OF THE URETHRA MORE DEEPLY SEATED.

The patient was a man in whom there were some evidences of constitutional syphilis, who complained of great pain over the bladder and in other parts of the pelvis (as well as in different portions of the body, though less marked), of frequent micturition, and of occasional difficulty in passing his water. The centre of the penis measured slightly more than three and three-quarters inches in circumference, and, according to the proportional standard adopted by Dr. Otis, the meatus should have admitted a No. 36 or 37 sound (French scale). Instead of this, however, it was found to be quite contracted in calibre.

In order to make an exploration of the canal, Dr. Otis introduced a urethrometer as far as the bladder, and gradually turned the scale until it marked 40, when the bulb gave the patient the sensation of just filling the urethra. The instrument was then gently withdrawn without meeting with any obstruction until the bulb came within four inches of the meatus, when it was caught. Dr. Otis remarked that just at this point, where the bend in the penis takes place in its flaccid condition, there is a natural contraction of the canal of greater or less degree, due to the folds of the mucous membrane gathered there. He therefore diminished the size of the bulb to the extent of three or four millimetres, but finding that it still could not pass, he pronounced the condition pathological; and it was not till it had been brought down to 33 that it could be gotten through the constriction. At the meatus it became necessary to reduce the instrument to 24 before it could be withdrawn.

With a probe-pointed bistoury he then slit up the orifice and the canal for about an inch beyond it until a No. 38 sound could be passed through it with ease; and stated that it was quite possible that when the wound had healed up (as he had frequently seen in other cases), it would be found that the apparent stricture beyond had been more or less spasmodic, and was due to reflex irritation caused by the constriction at the meatus. Even if it should be ascertained that there was a purely organic stricture, he would not advise that any measures should be adopted for its relief at present, for he deemed it prudent to avoid all such operations, if possible, in persons still suffering from syphilis.

With regard to the contraction of the meatus which had been present in this case, Dr. Otis remarked that the ordinary symptoms found in certain cases to be dependent on this condition were more or less constant pain in the pelvis, and extending down the thighs, frequent micturition, a sense of sudden restriction occasionally during urination, dribbling after passing water, and certain reflex nervous symptoms in various parts of the body, which varied in different individuals. Quite recently, he said, he had been consulted by a physician of this city, who for years had suffered great pain after defecation. His rectum had been examined, with a negative result, by competent surgeons, and finally, as a last resort, the sphincter ani had been ruptured in the hope of giving him relief, but still the trouble continued the same as before. Dr. Otis, on making an examination, found that the orifice of the urethral canal was abnormally contracted, and advised its enlargement; this was ac-

complished, and the result had been so extremely satisfactory that the gentleman now considered himself practically cured.

ABNORMAL CONTRACTION OF THE ORIFICE OF THE URETHRA WITHOUT SYMPTOMS.

Dr. Otis called attention to this case in order to contrast it with the preceding. Not only was the meatus unusually small naturally, but the patient, who was now suffering from constitutional syphilis, had formerly had a sore just at this point, which had still more markedly diminished its calibre. Yet, strange to say, the man suffered no inconvenience whatever, as far as could be made out, from having an orifice which could almost, without exaggeration, be called a "pin-hole meatus." It was one of those exceptions, Dr. Otis remarked, to which all general rules are subject; but, at the same time, he did not doubt that if the patient's life was spared, the condition would almost certainly give him more or less trouble in the future.

Progress of Medical Science.

CAFFEIN AS A DIURETIC AND CARDIAC STIMULANT.—Some time ago Prof. Gubler stated that caffein induced abundant and instantaneous diuresis in cases of cardiac dropsy. Dr. L. Shapter has recently reported cases which confirm this observation, and indicate a stimulating action of the drug upon the heart. In these cases the patients were in the latter stages of heart disease, with dropsy, dyspnoea, weak and irregular heart action, and diminished renal excretion. Caffein, in gr. iii. doses from one to three times a day, was given, after digitalis and potash had been tried unsuccessfully. All of the four reported cases showed rapid and marked improvement, the urine generally doubling in amount within twenty-four hours.

Caffein has been shown to be a vascular and cardiac tonic. Whether in these weak and dilated hearts it acts as a direct stimulant or chiefly by increasing diuresis and thus unloading the circulation it is impossible to say, but at any rate, its special value seems to be pretty well shown.—*The Practitioner*, Jan., 1879.

ANOTHER ANÆSTHETIC.—The Committee of the British Medical Association on the Action of Anæsthetics reports the results of six experiments with dichloride of ethidene, and is of the opinion that it presents all the advantages of ether or chloroform without their disadvantages. Its odor is agreeable, it produces rapid narcosis without much previous excitement, and its use is rarely followed by nausea or vomiting. It is administered by pouring the liquid on a piece of lint placed in a tumbler and this held over the mouth and nose. In from eight to twelve minutes complete anesthesia and muscular relaxation are produced. During the anesthesia respiration goes on regularly, the pulse is full and slow, and there is no pallor or blueness of countenance. From half an ounce to an ounce of the substance is used.—*Brit. Med. Journal*, Jan. 25, 1879.

IODIDES OF QUINTA AND CINCHONIDIA.—Dr. John Vansant, of the Marine Hospital Service, has discovered a method of obtaining the above iodides, and considers them very effective preparations. To a solution of equal weights of sulphate of cinchonidia and citric acid a like weight of potassium iodide is added. A yellow precipitate is formed, and this

being washed in ice-cold water, the protiodide of cinchonidia is left. It is a yellow crystalline powder, soluble in alcohol and hot water; it is odorless, but intensely bitter to the taste. Chlorine water added to a watery solution of this protiodide precipitates the biniodide of cinchona. This is a brownish-red powder, soluble in alcohol, and having a disagreeable metallic taste. When quinia is substituted for cinchonidia in these processes similar reactions occur, and the resulting compounds have nearly the same characters.

In regard to the therapeutic value of these substances, Dr. Vansant cannot speak positively of the biniodides, but he gives strong testimony in favor of the protiodides which he has used in a great many cases with the best results. They are indicated in conditions where both quinia and iodide of potassium are needed. In malarial fevers they are more prompt and efficient than twice the weight of any other preparation of the cinchona alkaloids. The watery solution can be combined with many other medicines without decomposition. The prescription which Dr. Vansant uses and recommends is as follows:

℞. Cinchonidiæ sulph.,
Potassii iodidi,
Acid. citric. ññ gr. xxiii.
Aquæ destillat. ʒ vss.

Dissolve the cinchonidia and acid in the water, then add the pot. iodid., and agitate.

Sig.: Dose, ʒ ss. t. or q. i. d.—*American Practitioner*, January, 1879.

CASE OF POLYPUS OF THE ŒSOPHAGUS SUCCESSFULLY REMOVED.—Mr. Annandale reports a case of œsophageal polypus which he removed from a patient aged seventy-six years, and which he considers worthy of record, as cases of polypus growing in this situation are rare. The tumor had been growing for five years, and used to "come out of his throat on to his tongue" upon coughing, after which it would return to the œsophagus spontaneously, or it could be easily reduced with the finger. It never gave any inconvenience except by its protrusion, there being no interference with swallowing or respiration. At the time of the operation the tumor measured four inches in length by one inch and a half in width, gradually tapering towards its peduncle, which was fully two inches long, and about the size of a lead-pencil. The attachment was to the left side of the œsophageal tube, immediately below its commencement. The peduncle was surrounded by the chain of an *écrasoir*, and slowly divided about one inch from its origin, thus removing about five inches of tumor. The structure of the growth was fibrous, resembling in appearance that of the dense fibrous polypus which grows in connection with the nasal cavities and the base of the skull. It was covered externally by mucous membrane. For some hours after the operation there was slight oozing of blood from the stump, but this soon ceased. The patient was able to return home in a fortnight.—*The British Medical Journal*, November 23, 1878.

SURFACE THERMOMETRY.—Surface thermometry is as yet in its infancy, but it is already of service in the diagnosis of disease, the prognosis, and in the treatment. The investigations of Dr. Squire demonstrate that the surface temperature of the chest is not always raised in the neighborhood of tubercular deposits, but when recent active disease exists such elevation is always present. Less recent disease, while undergoing active change, still shows an in-

crease both of surface temperature over the site of the morbid process, and of the axilla on the affected side. This local temperature subsides when local or general improvement is manifest, and is often entirely absent from an old deposit, now quiescent or not producing general disturbance. A useful means is thus afforded for recognizing the progress of the disease. With pleurisy and recent pleuritic adhesions the surface temperature is raised more than when these complications are absent. Acute pleurisy may raise the local temperature 4° or even 5° Fahr.; the affected side is always a full degree higher than the unaffected. Neurosal affections, so far as traced by the surface thermometer, seem to be attended by a lowering of temperature at the seat of a referred pain, or of a reflected irritation, and by an increase of heat on that of the originating centre.—*The Practitioner*, November, 1878.

CONTAGIOUSNESS OF PHTHISIS.—An attempt has been made by Dr. Tappeiner, of Meran, to induce tuberculosis in dogs, by causing them to inhale phthisical sputa. The animals were confined for several hours daily in a chamber, the atmosphere of which held in suspension the sputum of a case of phthisis distributed by means of a steam atomizer. Of the eleven cases experimented upon, all, with one doubtful exception, presented at the autopsies, after a period varying from twenty-five to forty-five days, well-developed miliary tubercles in both lungs; and in most cases tubercles were present to a smaller extent in the kidneys, and in some cases also, in the liver and spleen. The quantity of sputum necessary for the effect is certainly a very small one, for in three experiments, only one gramme was daily atomized in the air of the chamber. Miliary tubercles were also found at Munich, in the lungs of two dogs fed for six weeks with fifteen grammes daily of the same sputum as that used in the inhalation experiments; in six similar experiments at Meran the results were negative, all the organs being normal. It is remarkable that, with two exceptions, the animals, up to the time at which they were killed and found diseased, were well and lively, and indicated their disease neither by emaciation nor by other external symptoms. A preliminary account of these experiments of Tappeiner led Dr. Max Schottelius to make some similar experiments, not only with the sputum of phthisical individuals, but also with that of persons suffering from simple bronchitis, and with cheese, brain, and cinnabar. The result was that miliary tubercles were found in the lungs in all cases, and in equal quantity with both phthisical and bronchitic sputum. Cheese produced a smaller quantity; pulverized brain still less; and the cinnabar the least effect of all, merely a few whitish tubercles with pigmented centres, with an interstitial deposit of the substance, which had caused no inflammatory reaction. Tappeiner has also experimented with calves' brain in two cases, but with purely negative results. No changes in the lung followed, such as resulted from the inhalation of tuberculous sputum.—*The Lancet*, Nov. 23, 1878.

ON THE USE OF THYMOL.—Dr. Seyferth has published the results of his experience with thymol, which he has latterly employed exclusively in all surgical cases, and also in other cases requiring local antiseptics. In several cases of extensive burns it acted very satisfactorily, stopping at once the offensive discharge in cases that had been treated for days with caron oil, relieving the pain entirely, and producing a rapid recovery. The deep sloughs separated more rapidly than usual, and the granulations were not so exuber-

ant as in cases treated by carbolic acid; the resulting cicatrices also were not so deep and firm. A violent stomatitis due to the inhalation of caustic vapor, which had been treated for two days without relief by potassium chlorate and solutions of boracic acid, was quickly cured by a solution of thymol, of the strength of 1:3090. The same solution proved very effective in seven cases of diphtheria, three of which were very severe, and accompanied by great fetor of breath. Here it was used by injection into the nose, as well as into the mouth. Purulent coryza and suppurative aural catarrh do well under the thymol treatment; solutions of 1:4000 are well borne, and do not irritate either the nose or the auditory canal. Two cases of ophthalmia neonatorum were cured by the thymol solution, with which the eyes were washed out every hour; between the washings the eyes were kept constantly covered, at first with ice-compresses, and later with compresses of cotton soaked in the thymol solution. In some puerperal cases with offensive lochia, the vagina was washed out repeatedly, at first with solutions of 1:1000, and later with solutions 1:2000 and 1:4000; the results were rapid deodorization and a favorable action in the general condition of the patients. In two cases of old vaginitis with profuse, stinking discharge, a cure was obtained in fourteen days by irrigations with a solution of 1:4000, repeated three times a day, and followed by the introduction into the vagina of plugs of cotton dipped in thymolized glycerine. Dr. Seyferth keeps the following solution constantly on hand, and dilutes it to the desired degree whenever it is needed: Thymol, 1.0; spir. vini, 10.0; glycerin., 20.0; aquæ destil., 70.0. *M.—Allg. Med. Cent. Zeit., No. 62, 1878.*

PERFORATION OF THE APPENDIX VERMIFORMIS AS THE RESULT OF A TUBERCULAR ULCER.—In October, 1876, a woman, 25 years of age, was admitted into the Vienna General Hospital with a history of amenorrhœa for four months, and occasional pains in the abdomen for six weeks. Examination of the lungs, heart, liver, and spleen revealed nothing abnormal. The abdomen was moderately distended, and presented a transverse tumor below the navel, which was displaced upward. The skin over the tumor was red and injected. The tumor itself was soft, compressible, and contained air. It could be made smaller by pressure, and the anterior abdominal wall could then be felt at the bottom of it; an opening with infiltrated edges could be made out by palpation in this wall. The hypogastric region was firm and resistant, especially on the right side. The tumor was slightly enlarged by coughing. The percussion note over it was high-pitched and tympanitic. In December the tumor opened externally, and an artificial anus formed. The patient died of exhaustion in April, 1877. The autopsy revealed tuberculosis of the lungs, and peritonitis with adhesions of the intestines. In the fossa iliaca there was a large abscess which inclosed the vermiform process that had been perforated by a tubercular ulcer. A fistulous canal led upward and inward from the abscess to the abdominal opening.—*Bericht der k. k. Krankenanstalt in Wien, 1877.*

OSSEOUS TUMOR OF THE MAMMA.—At a recent meeting of the *Société de Biologie*, in Paris, M. Leloir presented an osseous tumor of the mamma, that had been removed from a slut in the laboratory of M. Vulpien. There was partial ossification of the fibrous tissue of the gland. According to M. Malassez, tumors of this nature are not rare in dogs.—*Le Progrès Médical, December 7th.*

A NEW MODIFICATION OF THE ANTERIOR SPLINT.—Dr. Roswell Park has made a modification of Nathan R. Smith's "Anterior Splint," which he claims to be an improvement both on it and on Hodgen's modification. The principal novelty in the splint as modified is the addition of an arrangement permitting movement of the knee-joint without interference with the position of the fragments, in cases of fracture of the femur. Dr. Park states, however, that it would hardly be justifiable to make any changes in the position of the limb until after the formation of callus. Another new feature in the splint is the introduction of an arrangement by which elastic extension can be made. The modified splint can be taken apart and packed in small compass, and is so arranged that it can be fitted to a leg of any size. It is applicable to almost all fractures between the hip and ankle, except those of the patella.—*Transactions of the Illinois State Medical Society for 1878.*

TREATMENT OF POPLITEAL ANEURISM BY ESMARCH'S BANDAGE.—Mr. Jonathan Hutchinson, at a meeting of the London Clinical Society, *Lancet, Dec. 21, 1878*, read the notes of two cases of popliteal aneurism treated as above. One was in a gentleman twenty-six years of age. An Esmarch bandage was applied, while the patient was under ether, to the entire limb, tightly below the knee, very lightly over the tumor, and tightly again on the thigh. The elastic strap was applied as tightly as possible in the upper third of the thigh, and after a little time the bandage was removed. Ether was kept up for an hour, and at that time the strap was removed and a horse-shoe tourniquet substituted. No pulsation ever returned in the tumor. The subsequent recovery was rapid and complete. The second case was less speedily successful. It was treated exactly as the first case, but pulsation returned. Three days later the same plan was adopted. The man was kept under ether for two hours; at the end of that time the strap was removed, and digital pressure was kept up for seven hours, at the end of which time pulsation had quite ceased.

CONTROL OF HÆMORRHAGE IN AMPUTATION AT THE HIP-JOINT.—Mr. Alfred Pearce-Gould, in amputating at the hip-joint, at Westminster Hospital, Dec. 7th, adopted the following plan of Mr. R. Davy's to control the hæmorrhage, and so completely that only about three ounces of blood were lost. The common iliac artery was compressed by carefully introducing a straight wooden rod, with a bulbous end, into the rectum for about nine inches. The length of the rod was about twenty-two inches. Slight elevation or depression of the handle, when once the instrument was brought to bear on the vessel, was enough to stop, or to allow the flow of blood.—*Lancet, Dec. 21, 1878.*

MILK A SOLVENT OF QUININE.—Mr. Batterbury calls the attention of physicians to the fact that milk is a good solvent for quinine, and also covers its bitterness. He has found that one grain of sulphate of quinine, dissolved in one ounce of milk, gives a solution with scarcely perceptible bitterness. Five grains can be administered in two ounces of milk without imparting to it a very disagreeable taste, and when the same quantity is added to a glass of milk all bitterness disappears. Mr. Palmer, of Birmingham, has confirmed these observations. He recommends, however, that the quinine should first be dissolved in glycerine in the proportion of a grain to a drachm.—*Gazette Obstétricale.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 8, 1879.

THE OVER-CROWDED PROFESSION.

THE three medical colleges of this city have just graduated over four hundred and fifty doctors of medicine. It is fair to presume that other schools throughout the country have contributed a proportionate number of recruits to the army medical. To the ordinary practitioner, not interested in the pecuniary success of any of these institutions, this increase of young doctors will be looked upon with considerable concern as to what the end may be. It is so universally admitted that the profession in this country is overcrowded, that it would seem like a work of supererogation to refer to the fact in the way of argument against large graduating classes. Still it is not only natural, but it is opportune at this time, to refresh our memories in regard to some points which refer to the present yearly system of glutting the market with medical talent.

The number of medical students in a series of years may be taken as a fair exponent of the number of the profession itself. The number of medical students in 1810 was 600; in 1871, 7,046; in 1876, 8,689; and in 1877, 9,646. And we find that the proportion of these to the population was in 1810, 1 to 12,000; in 1840, 1 to 6,800; in 1871, 1 to 5,700; and in 1877, 1 to 4,700.*

These figures show very plainly a steady increase of students every year which is out of all proportion to the increase of population. The same may be said for the profession, the members of which, by the continually increasing yearly additions, have swelled the proportion of one to six hundred of the population.

It is noticeable that the professions of law and theology, though both overcrowded, do not show of late years this same steady increase of students. The number of theological students in 1871 was 3,201, while in 1877 it had only increased to 3,965. In 1871 there were 1,722 law students in the law colleges; in 1873,

3,174; and in 1877, 2,811. While the increase in medical students amounts to nearly a thousand every year, that of the other professions has averaged within a hundred.

The medical colleges have not been behindhand in ministering to this much diffused aspiration to enter the noblest of professions. There were in 1877 eighty-two of these chartered institutions. These are distributed somewhat curiously throughout the States. Thus there are three at Washington, D. C., a city of 140,000 inhabitants; there are two in Massachusetts; ten in Ohio; all New England has six; all Missouri seven; Pennsylvania has four; Illinois and Kentucky each five. As a general thing it may be said that where there are few colleges in a State they supply a demand; where there are many, they demand a supply—and get it by superior inducements in the line of economy to the student of time and money.

Prof. Alfred Mercer, in an interesting address recently made to the council of the Syracuse (N. Y.) University, very pertinently says:

"From the cheapness of American diplomas, and from the few unenforced legal restrictions on the practice of medicine, with or without a diploma, or any known qualifications whatever, we have one doctor to every six hundred inhabitants, while a few miles from here, just over the Canadian border, they have only one to 1,200 inhabitants, while in Great Britain there is but one to 1,672.

France has	one to	1,811
Germany	"	3,000
Belgium	"	2,048
Austria	"	2,500
Italy	"	3,500
Norway	"	3,480

Thus, we have two doctors in the United States to one in Canada, nearly three to one in Great Britain, more than four to one in France, and five to one in Germany. The just relative proportion of doctors to population has been variously estimated at from fifteen to twenty-five hundred. The present average of the civilized world would probably fall within these limits."

We do not care to enlarge much upon the indications furnished by these statistics. The continual forcing of a larger and larger number of youths into a profession which they can never ornament and are likely to disgrace, is an evil that has been often enough discussed. Competition is very beneficial; over-competition begets envy, poverty, and dishonesty. When the proportion of physician to population is one to four hundred, medical ethics will probably cease to exist. The proportion as already stated as one to six hundred.

It is expected that they who proclaim evils will furnish remedies, and several such have been suggested. The endowment of the colleges so as to render them independent of the student's fees is a plan that is strongly recommended. But this project has violent opponents; besides, it would not alone be effective.

* Report of the Commissioner of Education for 1877.

tive, and it is at present impracticable. It certainly is a misfortune that medical colleges are now the poorest of all institutions of learning, and are compelled to obtain their incomes from the fees of their students. Hence, large classes mean pecuniary success, each year the number of graduates is increased, and each year the profession gets poorer. It is the State which can and ought to remedy the evil. Let it do here what is done in other countries take from the colleges their indiscriminate licensing power and bestow it on a board who shall admit to medical practice only those whose thorough education proves them worthy of it. By some measure of this kind we may be able to avoid that condition to which statistics now point, where every man will be his own doctor.

THE PLAGUE.

ALTHOUGH reports concerning the progress of the plague in Europe are quite contradictory, there does not seem to be a doubt that the epidemic is of considerable magnitude, and that it has spread from the localities in which it has been said to have originated. From Astrakhan it has extended to the adjacent villages on the left bank of the Volga, and has made its appearance at Saratoff and neighboring localities. The different governments of Europe have united for self-protection, and representative medical and sanitary commissions have been delegated to study the disease. As a result of these investigations, numerous data have been presented which are extremely interesting, both from a historical and scientific point of view. Our foreign contemporaries vie with each other in the amount of information upon these topics which they furnish to their readers.

The general characters of the present epidemic are in keeping with those which have been heretofore associated with the disease. The period of incubation is exceedingly short. In fact, the rapidity with which the majority of the victims are stricken is one of the appalling features of the disease. The duration of the disease, the average being three days, is also in keeping with the history of other visitations. Although this is the same form of bubonic plague which was observed in the beginning of our century in some parts of the East Indies, the glandular complication does not appear to be as prominent a condition as does the pulmonary affection, which is a rapid and destructive gangrenous pneumonia. The real cause of the disease is believed by Prof. Hirsch to be a blood-poison, which produces not only very serious typhoid symptoms, but induces local affections of the glandular system, in the shape of buboes, axillary and cervical enlargements, as well as destructive inflammation of retro-peritoneal glands and the spleen. The follicles of the intestines are never affected as in typhoid fever. Prof. Hirsch is of the opinion that the disease does not belong to the contagious group, but is of a zymotic type. In regard to the latter

point, his views coincide with the leading Russian authorities.

We are informed that a strict quarantine is maintained along the whole line of the Volga, that the province of Astrakhan is completely surrounded with troops, that infected villages have been burned, and that the most stringent measures are employed to limit the epidemic. In view of the extraordinary means adopted, and the privations to which the inhabitants of the infected districts are subjected, the end is not yet. There is, perhaps, nothing which is so liable to be overdone as a quarantine based upon the fears of an ignorant people. It so often defeats itself that practically it does more harm than good. Russia appears to be adopting the extremest measures, with a result which it is not difficult to anticipate. We know that quarantine to be effective must be reasonable, and that some middle ground must be taken between the means of preventing the extension of the disease on the one hand and the protection of the people exposed to the disease on the other. That the latter condition is not appreciated by the Russian government as it should be is quite evident. The *cordon sanitaire* is complete in its way, but this of itself will serve to explain why the people subjected to the same are demoralized, deprived of many of the necessaries of life, and are subjected to the usual unsanitary conditions which obtain under such circumstances.

THE ALTERATION OF PRESCRIPTIONS.

THE correspondent who favors us with a communication concerning the alteration of prescriptions by druggists is very unfortunate in his relations and surroundings. The facts which he presents show an amount of turpitude on the part of his pharmacist which is certainly alarming. We do not suppose that such experiences are by any means unique. In fact, we have in mind many instances that have come to our knowledge in which either the substitution of drugs has been made, or the quantities altered, at the discretion of the compounder. Of course this has been done by unprincipled and irresponsible druggists, and the physician who discovers the wrong is very quick to advise his patients to go to some trustworthy dispenser. Our correspondent has a similar method of remedying the evil. If, however, there is but one pharmacy in his village, he must dispense his own medicines.

A SEARCHER FOR URINARY CALCULI.—Dr. Edmund Andrews (Professor of Surgery in the Chicago Medical College) has devised a "searcher" for urinary calculi, which consists of a combination of Toynbee's otoscope and an ordinary short-curved, non-fenestrated catheter. It is claimed that by this instrument very small fragments of stone can be detected within the bladder. (For details see *Med. and Surg. Reporter*, Oct. 12th.)

Reviews and Notices of Books.

THE PHYSICIANS AND SURGEONS OF THE UNITED STATES. Edited by WILLIAM B. ATKINSON, M.D., Author of "Hints on the Obstetric Procedure," Permanent Secretary of the American Medical Association, etc. Svo, pp. 788. Philadelphia: Charles Robson, 1878.

THERE is a Spanish proverb to the effect that no man can be considered as having lived to any purpose who has neither written a book, built a house, or become the father of a boy. If to this standard the additional provisions are made that such a person, being a physician, must have written an article for a medical journal, must have been an officer in his county society, or have been, according to his own testimony, "an active worker in the profession," we can safely say that every one referred to in the volume before us is a man of reputation and "adorns the profession of his choice." Very much has been said in condemnation of the purposes for which this book was published; but, taking all the objections into account, we cannot look upon the venture as any more or less than a successful attempt to minister to the vanity of men who are either great already, or who wish to be. The histories are presumed to be truthful, because for the most part they are written under the direct supervision of the subjects themselves. From this point of view they are valuable as furnishing trustworthy data for obituary notices. As far as the records of facts are concerned, we believe the histories are trustworthy; but when any comments are indulged in, or attempts made at analyzing characters, considering the authorship of the same, there is naturally engendered that prejudice which lawyers attach to willing and perhaps partial witnesses. Still it is pleasant to know how old your friend is, where he was born, whom he married, how many children he has, and whether or no his wife or himself descended from any of the older and more influential families. All of this goes to prove that blood will tell. In proof of this we can refer to at least one hundred and twenty-five physicians so descended, who arose in their profession, became either secretaries of their county societies, aldermen of their villages, or made themselves specialists, and enjoyed large and lucrative practices. One of these gentlemen performed tracheotomy six times, another cut for hernia three times, another wrote a pamphlet which was reprinted in his village paper and resulted in his appointment as inspector of the school board, while another became trustee of a female seminary.

But Dr. Atkinson, in the generosity of his spirit, has doubtless found it hard to draw the line of distinction, and has perhaps trusted too implicitly to the statements of the subjects themselves. Under the circumstances, he has done much better than we could have expected, and, on the whole, has used his facilities to great advantage in publishing from different parts of the country interesting and instructive histories of many truly representative men. Of the whole number of autobiographies given (over twenty-six hundred) there are but two hundred, or, at most, three hundred subjects who have reputations which warrant any history whatever. These are the sketches which are interesting, and fully redeem the purposes of the publication. With the other two thousand or more there is much amusing reading, showing poor, vain human nature in all the various phases in which it can be studied. Particularly is this the case

when an autobiographer gets upon a hobby, and reminds us of the boy in the corner who succeeded in finding the plum in the Christmas pie. The establishment of a principle is a grand thing, whether it refers to the foundation of an empire or a new treatment for an ulcerated os, but it is hard to make unprejudiced persons think so. The work is illustrated with fifty steel portraits of the chiefest among the two thousand. The majority of these men are well known, and the likenesses are as good as could be expected when obtained without, of course, the consent of the originals. Of the remaining portraits, there are several which we presume are fine pictures; at all events, as mere works of art, they help to embellish the book and add to the general amusement of the reader.

In conclusion, we congratulate Dr. Atkinson on the success of his undertaking. He has certainly given us a very entertaining, well written, and instructive volume. If anything, he has done more than he promised. In a future edition we hope he will keep an eye on the man who has invented a speculum or a splint, who has found out a new method of extension, who was an officer of the American Medical Association, who calls a one-horse dispensary a hospital, or who has helped in any other way to make a reputation by "revolutionizing the practice of our art."

The work is supplied with an analytical index of subjects treated of by the distinguished men mentioned, but, being a very partial record, is of little value to the student. The typography of the volume is very bad, the ink inferior, and the paper poor.

AIDS TO CHEMISTRY: Specially designed for Students preparing for Examination. Part II.: The Metals. By C. E. A. SEMPLE. London: Baillière, Tindall & Cox, 1878.

IN a little work of about fifty pages, the most important facts about the metals have been very well condensed and arranged. A brief appendix gives a synopsis of the theory of chemistry. The book will be a very useful one to the student, for whom it is designed.

THE PRINCIPLES AND PRACTICE OF SURGERY. By JOHN ASHURST, JR., M.D., Professor of Clinical Surgery in the University of Pennsylvania, Surgeon to the Episcopal Hospital and to the Children's Hospital, etc. Second edition, enlarged and thoroughly revised, with five hundred and forty-two illustrations. Svo, pp. 1,040. Philadelphia: H. C. Lea, 1878.

THE second edition of this work comes to us with a declaration on the part of the author that no pains have been spared to render it worthy of a continuance of the favor with which it has heretofore been received. To this end, every portion has been revised, and a considerable amount of new material has been added. The reputation which this work has made for itself as a clear, concise, comprehensive and scholarly treatise upon surgery, is unquestioned. The large experience of the writer as a clinical teacher, his intimate knowledge of the literature of his subject, his authority as an accomplished scholar, have tended to make the work one of peculiar value and excellence. The arrangement of subjects is systematic and natural, while their treatment is surprisingly exhaustive, showing a most thorough acquaintance with the ancient and modern literature of surgery. The peculiar excellence of this edition is that the most recent improvements in surgical practice are noted, many of the references being made to articles which have appeared in the journals only a few months since. All authorities are carefully named, and the greatest pains seem to have been taken to

give each observer his due amount of credit. As a practical work for ready reference it is unsurpassed, and although compressed within the compass of an ordinary octavo volume, it has the scope of an encyclopaedia of surgery. It is well printed and profusely illustrated. The cuts are well selected, and many are original.

MEDICAL SOCIETY OF STATE OF NEW YORK.

Stated Meeting, February 5, 1879.

HEMORRHAGE DURING ABORTION—DISCUSSION ON DR. LUSK'S PAPER.

DR. FORDYCE BARKER, of New York.—MR. PRESIDENT:—I shall detain the Society but a few minutes in discussing the questions brought forward in the paper to which we have listened with so much interest, and shall simply speak upon a few special points. The paper is one of great importance, and I have no doubt the statements with regard to the great mortality resulting from hemorrhage associated with abortion will strike many of the profession with surprise. And yet I am sure that these statements will be confirmed by every one who carefully examines statistics upon the subject, and by all who have a large consultation practice. For my own part I have known of a greater number of deaths from hemorrhage occurring at the time of abortion than I have known from hemorrhage occurring at the time of labor. Indeed, I have seen but one case of death from hemorrhage occurring at the time of labor. But I have seen in consultation at least fifteen or twenty cases in which death occurred as a consequence of hemorrhage in connection with abortion. In fact, hardly a year passes that I do not see one such case. The importance, therefore, of arresting hemorrhage in connection with abortion has, to a considerable extent been overlooked by the profession.

But this is not all; even where death does not result at the time, there is a large class of cases in which the health of the patient is broken down by a hemorrhage which continues persistently, perhaps only moderate in degree, for weeks or months after the occurrence of an abortion.

Of this class of cases I see very many every year. And here is almost the only point where I shall take issue with the author of the paper, upon the statement that in abortions which occur within the *second* month of utero-gestation but little treatment is required. If he had qualified the statement by saying that *ordinarily* but little treatment is required I should have accepted it. But I have seen patients—it is only last week that I saw one—who were perfectly exsanguinated by a hemorrhage which occurred, it was supposed, and I argued, from the size of the ovum, within the eighth week of pregnancy. When I saw her she was perfectly pulseless; her respiration was rapid, and the surface of the body was covered with a clammy cold perspiration. The vagina was tamponed; the foot of the bed was raised, the patient's head was lowered, and stimulants in small doses were administered before I saw her. On examination soon after it was found that the tampon was getting quite moist with blood. It was removed, and then, by manipulation very much in the manner described by the author, I succeeded in

removing the ovum, which certainly could not have been more than eight weeks old.

So also in other cases I have several times been called to see patients who had profuse, even dangerous hemorrhage, from abortion occurring at this very early period in pregnancy. But I will agree with the author of the paper that these are rare cases.

Just this moment there comes to my mind the case of a lady, who, while at church on a Sunday, suddenly found herself flowing. She had only passed one menstrual period. She was taken from the church, placed in a carriage and carried home, and a physician was sent for. When, a few hours later, I saw her it seemed almost hopeless to attempt to save her life, she was so perfectly exsanguinated. This gives me an opportunity to speak of one resource for averting hemorrhage, sometimes dangerous in early abortions, almost the only resource not alluded to by the author of the paper. In early embryonic abortions the manipulations for the removal of the ovum described by him are not practicable, because the uterus is not yet sufficiently developed.

In these early abortions attended by profuse hemorrhage I am accustomed to place the patient in the position described in the paper, then place a rubber sheet under the patient, so as to protect the clothing and the bed perfectly, and conduct the water to run into a pail below, and then inject into the vagina a large quantity of very hot water, from 104 to 110° F. I believe that one may always be sure that this will positively, absolutely, and efficiently arrest the hemorrhage. In all the cases where I have resorted to this method I have never found it necessary afterward to subject the patient to manipulations for removal of the ovum. It has always come away spontaneously, sometimes the next day, or the next day but one, and absolutely without hemorrhage.

But, to return to the class of cases, to which I have already alluded, still in connection with the question of abortion occurring within the first two months, I see cases where the accident has occurred two or three months before, and the patient has become exceedingly anæmic, and the general system has become broken down by a constant and persistent daily loss of a small quantity of blood.

It is in this class of cases where I have found the wire curette most useful, and have seen the greatest benefit follow its employment. Sometimes its application is followed by one free hemorrhage, but it ceases entirely afterward. I have seen cases of this kind where the loss of blood continued for two or three months, although the abortion occurred when the patient had missed only one menstrual period.

One such case was a very curious one, inasmuch as the patient was a maiden lady, thirty-three years old, and whose character had never been called in question. She had passed but one menstrual period, and just before the eighth week after the last menstruation she was attacked suddenly with profuse flooding, which was arrested by the means then employed. But from that time she continued to lose blood in small quantities, perhaps not more than an ounce daily, and the loss persisted for nearly three months, when I was asked to visit her in consultation. I found that no vaginal examination had been made, because the patient had refused to submit to it. I insisted upon an examination, which was finally granted, and I found the uterus somewhat enlarged, the os somewhat patulous. On the following day I made use of the wire curette, and brought away nearly a wine glassful of material which, when submitted to one of our most competent microscopists and histologists, was found

to be the remains of a decidua formation. I was not nearly so surprised at the result of the examination as was the attending physician.

There is only one other point to which I will allude, and that is in relation to the tampon.

In cases of abortion, where I find it necessary to tampon, I never trust any kind of vaginal tampon, but always tampon the cervix uteri with a compressed sponge of proper size, and then only fill the vagina just sufficiently to keep the sponge in place. This, if properly done, is certain to arrest the hemorrhage, and, in from eight to twelve hours, during which the patient rallies from the dangerous exhaustion following the loss of blood, the cervix is sufficiently dilated to permit the safe removal of the entire ovum by the procedure described by the author of the paper.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 25, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

ACUTE OSTITIS—ITS DEVELOPMENT.

DR. HERTZMANN presented a microscopic specimen of acute ostitis, and made the following remarks upon the development of the condition:

The process of inflammation can best be studied experimentally on compact bone, which, by being touched with hot iron, promptly reacts upon the irritation. Besides the well-known disturbances in the vascular system, the tissue itself also invariably partakes in the reaction. First the lime-salts are dissolved out in certain territories around the bone-corpuscles, this being a merely chemical action; next the glue-giving basis-substance is liquefied, and thus the protoplasmic condition of the bone-tissue re-established. As the network of living matter is present also in the calcified basis-substance, the liquefaction of the latter is the only requirement for re-establishing the embryonal or medullary condition of the bone. By increase of the size of the granules of living matter within the protoplasm, new medullary elements originate, these representing what has been termed the inflammatory infiltration. Up to the eighth day the compact bone, through the process of inflammation, is transformed into cancellous structure, and all medullary spaces are crowded with medullary elements, newly formed blood-corpuscles, and capillary blood-vessels. The medullary elements are connected with each other by delicate threads of living matter, and represent a tissue, though an embryonal, undeveloped tissue. Through rupture of the connecting threads isolation of the medullary elements results, and then we have pus-corpuscles before us, the sum total of which is termed an abscess. Against the views of S. Stricker, who considers all inflammatory elements as pus-corpuscles, H. maintains, that even the inflamed tissue remains a tissue with union of all constituent elements, lest suppuration should be the termination of the inflammatory process. The old doctrine of the two main varieties of inflammation, viz., the plastic and the suppurative, is fully corroborated by his recent microscopical researches.

COMPOUND PUNCTURED WOUND OF CRANIUM—REMOVAL OF FRAGMENTS—MENINGITIS—DEATH.

DR. BRIDGON presented a specimen of the above, and gave the following history:

E. B. Staats, aged 61, native of New Jersey; married; carpenter; was admitted to the Presbyterian Hospital, January 11, 1879.

On the previous day, whilst passing a building in the course of demolition, he was struck on the head by a falling brick and knocked down insensible; he came to himself in a few minutes, and then observed that he could not see with his left eye, which condition also passed away in a short time.

There is a linear wound of the scalp about an inch and a half long, situate on the summit of the vertex, and about an inch to the right of the median line; beneath it is a fracture of the skull, small, and in the form of a semicircle, the convex border of this fragment driven in beneath the inner table of the adjoining bone, and impacted between the fragments was a small lock of hair; a hole was nibbled away from the adjacent bone large enough to admit an elevator, with which the depressed bone was raised and detached, and immediately beneath was found a small pointed and detached fragment from the inner table about a quarter of an inch long, its apex pointing toward the dura mater.

The margins of the bone were smoothed off by the rongeur, and the wound was dressed with proof-spirit.

Everything went well until the 14th, when he had a chill followed by rise of temperature and headache; pupils were rather contracted, and there was some intolerance of light.

Headache continued about the same until the 17th, when it was aggravated by two or three attacks of vomiting, and it was then remarked that he did not respond with his usual promptness to questions.

19th.—Mental hebetude has deepened into stupor; pupils much contracted; pulse, which has never been over a hundred, is now below 80. The dura was found bulging in the wound, and there was no pulsation in it. An incision half an inch long was made through the membrane, giving exit to a tiny rivulet of pus, which could not be estimated on account of a pretty free venous hemorrhage. The blood was purposely allowed to flow for a few minutes, and was then readily arrested by very moderate pressure. While the flow continued, he quite lightened up, and it was noticed that his previously contracted pupils dilated; but the improvement was evanescent, and he relapsed again into a condition of stupor.

On the night of the 20th he had a severe chill, several involuntary discharges from the bowels, and retention of urine. His temperature on the following morning 103°. Coma was profound; there was occasional twitching of the muscles of the face; no convulsive movements of the extremities; reflex movements abolished on the right, and only very slight fibrillary movements could be elicited on the left side.

He continued in about the same condition until the 21st, when he died. Twenty minutes before death his temperature was 104°.

Autopsy, twenty-six hours after death.—Rigor mortis well marked. A crucial wound of scalp midway between nasal eminence and the occipital protuberance, and one inch to the right of mesial line. Opposite the centre of this was a circular opening in the skull. The floor formed by the dura was depressed. On removing the calvarium, which was very thin, there was found considerable injection of the sinuses, and a layer of false membrane capping the left hemisphere and adherent to the parietal arachnoid. The pia on both sides was injected, but much more so on the side opposite the injury. There was a layer of greenish pus in the subarachnoid tissue on that side also. The evidences of inflammatory mischief were much less marked on the side of

the injury, and the brain itself was rather anæmic than otherwise. There was no collection of pus in the immediate vicinity of the wound.

There were old adhesions in the chest, and evidences of old bronchitis, and in one lung a small patch of fibroid induration. All other organs were found healthy.

Dr. Briddon remarked, in conclusion, that the general results of trephining were disastrous, even when the operation was most imperative, as for instance, in punctured wounds of the cranium. He had heard of two cases only in the records of the hospital (Presbyterian) in which such an operation had proved successful. These had been performed by Dr. S. B. Ward, a former surgeon of the institution. In Paris, where the operation had been quite fashionable, there have been no recoveries for ten years. He believed, however, that we were approaching the period when the indications for operation would be more exactly defined than at present, and when there would be a favorable reaction in favor of operative interference.

Dr. Keyes concurred with the latter opinion. He believed many of the fatal results were chargeable to the fact that the cases were not operated upon until beyond hope. Again, he had reason to believe that trephining, in common with other grave operations, is destined to have its general mortality reduced by a more general adoption of the antiseptic system in hospitals.

CYST-ADENOMA OF THE BREAST.

Dr. C. C. LEE presented a cyst-adenoma of the breast, which he had removed by operation from a patient in the State Woman's Hospital. She was a German by birth, aged twenty-one years, married, and the mother of one child. Nine months ago, and while in the fourth month of pregnancy, she noticed for the first time a lump on the left breast, an inch below and to the inner side of the nipple. The growth increased gradually, and was the seat of lancinating pains. When the child was five months old, she was compelled to cease nursing it, and after consulting several physicians, with varying results as to opinions, she finally applied to the Woman's Hospital for relief. On examining the tumor, Dr. Lee discovered that there was indistinct fluctuation, that the nipple was not retracted, and that the general appearance was in favor of non-malignancy. It was considered advisable to remove the growth, and the operation was done by an S-shaped incision. On cutting into the tumor after its removal, the contents were found to consist of a cheesy, fatty material, similar to that seen in strumous testes.

The wound healed promptly, and ten days after the operation, and at the time the case was reported, the patient was convalescent.

THREE VESICAL CALCULI REMOVED BY THE SUPRA-PUBLIC OPERATION.

Dr. Keyes presented three specimens of stone, all removed from the bladder by the supra-pubic operation. The patients died in each instance, and Dr. Keyes stated that his reason for presenting the stones was not from any peculiarity either in the operation or in the specimens, but that he might put the cases upon record, since he considered it, perhaps, more important to report failures than successes. Dr. Keyes had removed stones from the bladder by lithotomy and lithotripsy, all told, thirty-eight times. He had lost four cases; three of these were the supra-pubic operations to be detailed. The other fatal case was a

broken-down subject of sixty-five, with a large, hard stone, which had caused much suffering for many years.

Of the three cases, the first ought to have recovered by any operation; the last two would have died, doubtless, under any operation.

CASE I.—X—, aged 75, examined in May, 1877, was found to be in perfect health, with a prostate only moderately enlarged, not very much cystitis, and presenting every evidence of healthy kidneys, so far as the urine could decide the question. The stone was caught in a lithotrite, and measured $1\frac{1}{4} \times 1\frac{1}{8}$ inches. The stone was very hard, and lithotripsy at a single sitting, for large stones, was not known at this date (May, 1877) to Dr. Keyes. The nervous, irritable temperament of the patient, and the size of the stone, made slow lithotripsy undesirable, and lithotomy was proposed, but declined by the patient.

Two and one-half months later, during July, the patient's symptoms became more distressing, and he was brought back by his physician, demanding lithotomy.

The supra-pubic operation was performed. The bladder was first thoroughly washed out with carbolic water, and left empty. An incision in the median line above the symphysis reached the bladder promptly, its exact position being made evident by the point of a steel sound passed through the urethra. The bladder was held up by two strong silk threads passed through its whole thickness on either side, and between these threads the viscus was opened. The peritoneum was not molested. A little carbolic water was found in the bladder. The stone, weighing a few grains over an ounce, was easily extracted with straight forceps. A soft rubber catheter was placed in the wound, attached outside to a tube, so that it might act as a syphon. The bladder-wound was sewed up, and the outside wound left open. Certainly not one ounce of blood was lost. The whole operation occupied less than half an hour.

The patient died early on the third day, with a temperature of $104\frac{1}{2}^{\circ}$. There was no tenderness over the abdomen, excepting at one spot low down in the left groin, near the middle line—suggestive of cellulitis. Drainage continued perfect until the end, and there was no suppression of urine. Autopsy refused.

CASE II.—X—, age 73, had been cut sixteen years previously by Dr. Van Buren in the perineum, and six phosphatic stones removed. He had atony of the bladder, and after a few years he became tired of washing out the viscus, and stones gradually reformed. He visited Dr. Keyes for the purpose of being sounded. The urine contained albumen and casts, and there was much cystitis. A searcher, gently introduced, immediately encountered phosphatic stones.

The patient was laid up for two weeks with cystitis, as a result of this exploration, and no operation was advised. His sufferings, however, continued to torment him until he demanded relief. A lithotrite was therefore passed, one stone caught, crushed once, and nothing more attempted. This operation aggravated the cystitis, and, with Dr. Sands in consultation, supra-pubic lithotomy was decided upon.

The operation was short and without complication; one crushed and two whole stones, weighing collectively three ounces two drachms and ten grains, were removed. A soft catheter was left in the unjured urethra.

The drainage was effective; no suppression occurred; but the wound did not unite, and the patient gradually became delirious and uræmic, and died

on the seventh day. Autopsy revealed granular kidney and slight pyelitis.

CASE III.—X—, aged 65, was operated on in Bellevue Hospital, October 29, 1877, by lithotripsy, and a stone of one and a half inch diameter, composed of urates and uric acid, caught and crushed several times. The size and hard, sharp edges of the fragments caused some cystitis, and after a rest of a couple of weeks Dr. Keyes decided to give ether, and crush as much as possible at a single sitting, using a new lithotrite of Reliquet's, which was warranted not to clog. Collin et Cie., the makers. However, had modified the instrument in its construction in such a way that it did clog admirably. After a few fragments had been crushed, it became evident that the blades were clogged. No efforts succeeded in getting rid of the fragments which filled the female blade. The instrument was therefore withdrawn and enough force had to be used during its extraction to divulse (slightly) the urethra at its point of natural constriction, about two inches from the meatus.

The patient had a chill, and did badly. His cystitis increased, and supra-pubic lithotomy was performed, drainage being managed by a convolvulus catheter passed through the *bas-fund* and out at the anus.

The patient did not rally. Death occurred on the second day, and surgical kidney was found on both sides at the autopsy.

URIC ACID CALCULUS OF LARGE SIZE REMOVED BY BIGELOW'S METHOD.

Dr. WEIR exhibited the crushings of a uric acid calculus, weighing 360 grains, which were removed by Bigelow's method, from a man aged 73 years. The patient appeared in robust health, notwithstanding he had the history of frequent attacks of renal colic extending over a period of eight years, and had suffered from symptoms of vesical calculus for three years. The stone was crushed in fifteen minutes, the whole operation occupying forty-two minutes. The patient did well for six days, at the end of which time he was allowed to go into the solarium of the hospital. The second day after this he was seized with a chill and severe pain in the left kidney. The chill was followed by a temperature of 106° F. The chill was repeated the following day, with a recurrence of the temperature. Diarrhea, persistent vomiting, and hiccough succeeded, and he finally sank in a somnolent condition, dying a month after the operation. Except for the first few days following the urethral chills, the temperature ranged from 99½° F. to 102° F. The urine during all this time was passed freely, and was not markedly changed in character.

At the autopsy a typical example of surgical kidney was found upon the left side, and a cystic degeneration of the corresponding organ on the opposite side. The left ureter was blocked by a number of small calculi, and apparently this had been the cause of the inflammation which had invaded the kidney. The bladder was uninjured.

UN-UNITED FRACTURE OF THIGH.

Dr. Weir presented a second specimen, which consisted of an ununited fracture of the thigh removed post-mortem from a Scandinavian sailor. Fourteen months before admission the patient sustained the fracture by a fall on shipboard. He had been treated by splints and extension for four months, with unsatisfactory results. When admitted to the New York Hospital, the shortening was two and a half inches, and motion was free. The first method of ex-

citig inflammation for the deposit of new bone was made by forcibly rubbing the ends of the bones together, applying a plaster bandage and Buck's extension. This failed, and when Dr. Weir came on duty he bored the ends of the fragments with Brainard's drill. The point of one of the drills broke and remained in the bone. The operation was performed on the 24th of December, and the patient did well until January 2d, when he was seized with a chill which ushered in an attack of erysipelas. The latter appeared to originate in an abrasion over the tibia, the result of the previous application of plaster-of-paris to the part. The redness extended upward on the thigh, but did not reach to the non-union. At the autopsy the knee-joint was moderately infiltrated with pus. How to explain the latter condition was difficult, in view of the fact that no osteo-myelitis had been excited by the operation, except by a lymphangitis, as recorded in several cases by Verneuil. The ends of the fragments were rounded, supplied with a smooth membrane, and surrounded by ligamentous tissue. It was quite evident that nothing short of resection of the ends of the bones would effect bony union of the parts.

CHICAGO GYNECOLOGICAL SOCIETY.

Regular Meeting, Dec. 27, 1878.

DR. D. T. NELSON, IN THE CHAIR.

(Special Report for MEDICAL RECORD.)

PLACENTA PRÆVIA.

Dr. E. O. F. ROLER read a report of a fatal case of placenta prævia, with remarks. He thought the descent of the ovum to the lower part of the uterine cavity depended on a failure to make prompt attachment at the upper part, from faulty decidua, or late fecundation, or separation of the mucous surfaces of the uterus "to such an extent as to furnish an easy passage through its cavity." The last condition was less likely to exist in primiparæ. He thought the ovum might become attached to the cervical lining, as well as just within the internal os; in the former case "abortion at an early day must be inevitable," for the os internum would prevent the invasion upward of the growing ovum, and, as the os externum has slight powers of resistance, it would become early distended and dilated, and expulsion would result. He had met with one case of this kind: abortion had occurred at the third month, with alarming hemorrhage, that neither ergot nor ice locally applied had power to check, but which ceased at once on the injection of persulphate of iron. After discussing the various definitions of placenta prævia, he stated his own to be "implantation *over* the os internum within the cavity of the body of the uterus." He did not believe in the doctrine of the development of the uterine neck during the later months of gestation. Were such doctrine true, in placenta prævia there would always be hemorrhage during this time, which was not the case, some cases wholly escaping hemorrhage until the beginning of labor. He therefore regarded hemorrhage, until near the end of gestation, in placenta prævia, as purely *accidental*.

As to treatment, he was inclined to the view that the removal of the placenta, "to the extent of clearing the canal for the advancing fetus," was indicated. He thought it well to separate the placental attachment one half the circumference of the neck, and to rupture the membranes and bring down the border of the placenta, as occurs in the accidental variety. The advancing head or breech would then act as a com-

press. For tampons during dilatation of the neck he preferred plngs of oiled cotton batting. Artificial dilatation was generally a failure. Early rupture of the membranes should be resorted to only in cases of partial presentation, or where the placental edge could be brought down. Rupture of the membranes should be avoided as a preliminary step until full dilatation. Puncture of the placental mass was of doubtful propriety.

The case he had to report was of a woman of forty, a multipara. She had had dyspepsia for years, and profuse menstruation. The first indication of placenta prævia occurred about forty-eight hours before labor came on, when profuse discharge of blood came on without pain. Prof. Nelson saw the case first, in his absence. The os was found undilated, but the hemorrhage had ceased. He pushed his finger through the cervix, and felt placental tissue. In two days flowing returned, but not excessive; soon it increased, and on the arrival of Dr. R. the patient was faint. Pains were good. The os was high, rigid, and dilated to just admit the index-finger. The hips were raised, and attempts made to introduce Barnes's smallest dilator, but without success. Next a rubber colpeurynter, covered with a linen handkerchief, was introduced, pressed against the os, and filled with water, and a dose of ergot and brandy administered. Soon blood appeared freely by the side of the bag, and it was withdrawn and the hand rapidly passed into the vagina, the index-finger forced through the os, now more dilated, and swept around the entire circumference, and the placenta detached. The membranes could not be reached, the part presenting forced strongly down. The hemorrhage now increased, and was most plentiful just following each pain. The vagina was now tightly plugged with water of cotton batting "squeezed out in soapy water." Pains soon assumed the bearing-down quality; the patient was showing more exhaustion, and the hemorrhage was not entirely stopped. Thinking the os must be fully dilated, Dr. R. now rapidly emptied the vagina, and easily dilated the os sufficiently to admit the hand to the uterus. He ruptured the membranes and caught the knees, and made version easily. As the hand was withdrawn, the placenta came with it. The body being delivered, the head hung in the lower strait, and was delivered with forceps. During the operation of version the hemorrhage was frightful. The uterus contracted feebly, and the oozing of blood did not wholly cease. Tincture of iodine and water (one part to six) was injected into the uterus, and the bleeding ceased. The patient was nearly moribund, but reacted somewhat under the use of injections into the rectum of brandy and coffee. In half an hour hemorrhage recurred, notwithstanding the uterus seemed fully contracted. The diluted iodine was again injected, but death soon ensued.

In the discussion of Dr. Roler's paper

Dr. BYFORD gave his views at length on the subject of placenta prævia. He believed the distention of the part of the body near the neck begins in the latter part of the eighth month, and that of the cervix is accomplished mostly during the ninth month. The woman was in great danger as soon as hemorrhage began, and artificial premature delivery after the manner of Greenhalgh was advisable. If in any case the hemorrhage was not so urgent as to require the tampon at once, the liquor amnii should be evacuated, as it would stimulate the uterus to contraction, and cause the presenting part to press upon the placenta and constrict the bleeding vessels. The tampon of Dr. Roler he regarded the best; each

pledget of cotton should have attached a string, and the vagina should be packed so full no blood could escape.

DR. D. L. MILLER said he thought that after the fourth month the cervical zone of the uterus developed, and that it developed beyond the growth of the placenta. Therefore, in placenta prævia, there was sliding of tissues upon each other, which caused rupture of vessels and bleeding. This hemorrhage he regarded as *unavoidable*. He favored the treatment of Greenhalgh. The tampon which he preferred was made of a strip of cotton cloth like that used for a roller. One end was carried to the os and the remainder introduced till the vagina was full.

DR. SAWYER inquired if the uterine tissue over which the placenta was implanted was not more friable than other parts of the uterine substance. He had attended a case of perfect placenta prævia which resulted in death, in which there was found on post-mortem a rent four inches long in the uterine tissue at the point referred to. No undue violence was used in the labor.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

(Reported for THE MEDICAL RECORD.)

THE CURE OF HABITUAL DRUNKARDS.

A SPECIAL meeting of the Philadelphia County Medical Society, Henry H. Smith, M.D., President, in the chair, was held on Wednesday evening, February 26th, to receive the report of a special committee consisting of Benjamin Lee, M.D., Chairman, Drs. R. M. Girvin, R. A. Cleeman, William Pepper, Andrew Nebinger, Frank Woodbury, John B. Roberts, Geo. Hamilton, J. G. Richardson, and William Goodell, which had been appointed to consider and report upon the best means of coping with the evil of intemperance.

This subject has been under earnest and thoughtful consideration for some time past by certain members of the Philadelphia County Medical Society. The subject was first proposed long since by Dr. Robert M. Girvin, of West Philadelphia, to whose energy and perseverance the successful development of the measure is largely due.

The attendance of members at the meeting was very large.

The following is the draft of an act which the committee submitted, as embodying all the necessary details of the plan which they have devised for the treatment of confirmed inebriates:

SECTION I.—*Be it enacted, etc.*, That on the petition of any inebriate or habitual drunkard, by any relative or next friend who shall make the usual affidavit thereto, setting forth therein that now being addicted to the use of stimulants or narcotics, or both, he or she has become an habitual drunkard, and is unable to take care of himself, or herself, or property, and praying for the appointment of a committee for the purpose, with the certificate of two or more respectable physicians attached, whose signature and respectability shall be certified to by some magistrate or judicial officer that, after a personal examination of the petitioner within one week of the date of the certificate, they do fully concur in the facts stated in this petition, it shall be lawful for any Court of Common Pleas to appoint a committee of the person or estate, or both, of such habitual drunkard, with like effect as if made on the return of an inquisition under the

fourteenth section of the act to which this is a further supplement. (This refers to an act passed by the State legislature in 1836, and entitled, "An act relating to lunatics and habitual drunkards.") That the committee of any habitual drunkard, appointed under this act, shall, with the written consent and approbation of the court making the appointment, have the power of confining such person for treatment and care in any inebriate asylum, established, or to be established, under the laws of this State, for a term of not less than four or more than twelve months, and that such period of confinement may, by said committee, with both consent and approbation of the court, be from time to time extended for such periods as may be necessary for his or her complete recovery, cure, and reformation, and that said committee may also, with the written consent of the court, release at any time the said habitual drunkard from confinement.

That persons placed in any such inebriate asylum under the provisions of this act may be discharged by the managers, in whom the government of the institution is vested, pursuant to such rules and regulations as they may from time to time adopt in relation to patients and the management of the institution.

That the estate of any habitual drunkard placed in any such inebriate asylum under the provisions of this act shall be liable for his or her support and treatment therein, and the cost and expenses incurred in his or her case of all necessary proceedings.

That the term "habitual drunkards," under the laws of this Commonwealth, shall be construed and taken to mean any person addicted to the use of stimulants or narcotics, or both, as to be incapable of taking care of himself or herself, or their property.

The draft was adopted after considerable discussion, together with the following form of petition, to be signed by the officers and members of the Society, and to be sent to Harrisburg with the bill:

To the honorable the Senate and the House of Representatives of the Commonwealth of Pennsylvania in General Assembly met:

The undersigned, officers and members of the Philadelphia County Medical Society, respectfully represent that the well-established fact that the habitual, excessive use of stimulants and narcotics diminishes the moral powers, depraves or destroys manhood, and unfits its victims for the discharge of domestic business and civil duties, calls for legislative interference for the protection of the individual so affected, of his or her family, of society, and of the State.

Under existing laws in this State the property of the habitual drunkard can be protected, but he himself is allowed to drift into helplessness, crime, imbecility, and the grave, with no legislative effort to save him, beyond the meagre and inadequate Act of 1836, for those partially insane.

There are but few drunkards who would not gladly give up the evil habit of intemperance if they were able, but their moral force is gone. They need help. Such help can be most effectively rendered, in the opinion of your memorialists, by legal restraint and protection.

That the drunkard can be cured, restored to his family and made a useful member of society, is proved by the testimony of physicians, and by the happy results of treatment in every inebriate asylum in the country.

To establish a cure of the inebriate, it is absolutely necessary that he should abstain entirely from the use

of stimulants and narcotics for such a length of time as will allow his system to recuperate from the ravages of disease induced by past indulgence, and to free itself from every particle of the poison. He is rarely able to do this of his own accord, and his friends have not sufficient control to compel him to do so. The result can only be accomplished by legal restraint in a hospital established for that purpose.

That he should not be placed in an insane asylum is testified to by almost every one in charge of such institutions.

Your memorialists would call your attention to the fact that action was taken upon this important subject by the Legislature of the State of Connecticut more than four years ago. They firmly believe that such action on your part would save hundreds of valuable lives, and hundreds of thousands of dollars to the Commonwealth annually.

To this end they beg respectfully to memorialize your honorable bodies to pass such an act as will give power to place the habitual drunkards and dipsomaniacs in properly constructed and responsible hospitals, where they can be restrained for such a length of time as will enable them to regain their power of self-control, and your memorialists will ever pray, etc.

The bill and petition were then referred to the same committee for presentation to the Legislature.

Dr. Benjamin Lee, Treasurer of the State Medical Society, Chairman of the special committee, and one of the principal advocates of the proposal, in the course of a conversation, gave the following expression to his views: "Under our present laws," he said, "insane persons and habitual drunkards are classed together. A measure entitled, 'An Act relating to lunatics and habitual drunkards,' passed in 1836, provides that any Court of Common Pleas in the State may issue a commission to inquire into the lunacy or habitual drunkenness of any person in the Commonwealth. This commission is given power to take charge of the property of the individual, and out of it to make provision for the support of himself and family. This law, however, has one flaw—while it allows the commission to place a lunatic under restraint it makes no provision for the incarceration of an habitual drunkard. It is this error that we desire to remedy. We hold that habitual drunkards may, in almost every instance, be reclaimed, and be made useful members of society, instead of being burdens upon it. This, however, can only be done by putting them entirely out of the reach of spirituous liquors, until a cure has been effected. Drunkenness is a disease which the victim is powerless to overcome without outside help. While under confinement he could receive such medical treatment as would restore the organs, especially the liver and stomach, to their natural condition, and in that way remove the craving.

"The system has been tried and has proved successful. We have nine hospitals for inebriates in the United States, and statistics show that out of 5,000 admissions, thirty-four per cent. of the patients have been cured, and forty per cent. benefited, while only twenty-six per cent. were returned as incurable. Dr. Forbes Winslow, the eminent English authority on insanity and intemperance, says that inebriate institutions are the crying want of the age. Dr. Thomas Kirkbride, the physician in charge of the Pennsylvania Insane Asylum, has placed on record his opinion that 'drunkards cannot do anything without help, and that without restraint it is impossible to

effect a cure,' while the State Board of Charities have expressed the opinion that 'inebriates need appropriate methods of restraint, attendance, and treatment, quite as much as the insane.' The proposed measure will merely authorize the confinement of inebriates in a suitable institution, leaving the institution to be established hereafter. In many cases the habitual drunkard is himself anxious to reform, and often he makes constant and energetic attempts to do so, but without avail. In such an asylum as we propose, a cure might be effected."

Correspondence.

THE ALTERATION OF PRESCRIPTIONS BY DRUGGISTS.

TO THE EDITOR OF THE MEDICAL RECORD.

STR.—Dr. Fordyce Barker's article on "The Alteration of our Prescriptions by Druggists," vide *MEDICAL RECORD*, page 22, Jan. 1, 1873, is an effort in the right direction. Not long ago a patient suffering from cystitis was given the following prescription: R. Ammonia benzoas, ʒ iij.; Buchu fl. ext. (Squibb's), ʒ iij.; Syrup simplic., ʒ i. M. S.: One tablespoonful every four hours.

I requested the patient to bring the medicine to me before using it. On inspection, the ordinary flaky appearance of the ammonia benzoas floating in the liquid was absent. I requested the prescription clerk to explain his method of dissolving the benzoate. "Why," said he, "I put them together in the mortar; rubbed them a little, and they dissolved (the flakes)." I immediately repaired to the store and asked the proprietor for an ounce of the benzoate. He said it was the first call he had had for it, and had never kept any in the store! There was no other conclusion than one in this case. He had not confounded it with carbonate, for he said he had used the benzoate. The reason for combining it with buchu was, my patient refused to take it in pill form.

In consultation with Dr. S——, in a case of phlegmonous erysipelas, we gave the following prescription: R. Potas. chlorat., ʒ ss.; Tr. ferri chlor., ʒ ij.; Syrup aurant cort., ʒ ij. M. S.: One tablespoonful every four hours. Having occasion to visit a pharmacy I found the messenger awaiting the compounding of our prescription. I overheard the following conversation: "We are entirely out of the chlorate, so I put in the acetate." This was said in an undertone to a member of the *firm*, whereupon the medicine was passed over the counter to the messenger. Dr. S—— having written the prescription, they did not know that I was acquainted with its construction or anything concerning it. In fact, they were not aware of my presence.

Another kind of substitution sometimes occurs, viz.: through presumption, in this case, a small boy was sent to one of our drug stores with a slip of paper, on which his mother had written, "One ounce of powdered rhubarb." On his way to the store he lost the paper. He told the clerk of it, and then said it was something like "rube" or "red," but could not tell the whole word. A powder was sent by the boy. The mother took a teaspoonful of it. I saw her *two* days thereafter. Her face and neck were swollen and congested. Her eyes were congested and glaring. Abdomen was greatly distended with gas, tender and reddened. The pain in the throat, œsophagus, stomach,

and, in fact, the whole alimentary canal, was very excruciating. Marked anorexia, pulse weak and thready. She said "her whole insides were on fire." The odor of mercurial salivation was simply horrible. A continuous stream was flowing from the angles of the mouth. After her recovery she related in the presence of the boy the aforementioned circumstances regarding the purchasing of the powder. There was neither writing nor label on the package. The powder sent her was the red oxide of mercury. I at once repaired to the store from which the powder was purchased, and the clerk denied nothing, but said that he "thought he wrote poison on the outside." Physicians are in some respects simply "drummers" for the pharmacists. We send them their best class of business and rely on their honesty and skill, and, in fact, place the lives of our patients and our success as practitioners in their hands. Not only have these things happened here, within fifty miles of the principal city of this continent, and in a place of a population of about 14,000 souls, but I know of instances (one happening to myself) where the pharmacist induced a patient to have my prescription laid aside, persuading him in the meantime to have in its stead a bottle of a nostrum compounded and patented by himself. Is it not time to have a stop put to such outrageous proceedings?

Yours truly,
REGULAR.

JANUARY 27, 1879.

INGROWING TOE-NAIL.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—My attention was directed to the following passage in an article by Dr. J. D. Neet, *MEDICAL RECORD*, 1877, page 557: "There is a method of treating this nail that is quite as satisfactory as evulsion, far less painful, and, above all, is an eminently conservative process. In the first place, drop a few drops of liq. potassæ (ʒ iij. to ʒ j., etc.), upon this ulcerated surface, with its imbedded nail, four or five times a day." Continue this till the granulations have receded, so as to expose the edge of the nail, then "take a thin piece of selected cork—which is gently inserted under the nail." The following case will attest the merits of this treatment: Case, R. D. In May, 1874, a cow stepped on the great toe of her left foot and forced the nail in the flesh. When she applied to me, I found the nail one-third covered with flesh. I commenced using liq. potassæ ʒ iij., water ʒ j., as I supposed the above to mean, but was disappointed with the results, so I made a solution of caustic potassæ, ʒ iij., water, ʒ j., and applied twice daily. The granulations receded rapidly, and the edge of the nail was soon visible. I then inserted wedge-shaped pieces of cork under the nail, increasing the thickness of the wedge as the nail would rise from its bed. It is now three weeks since treatment was suspended, and the patient is able to wear her shoe, with no uneasiness of any kind.

A most happy plan of treatment, where the patient will await the results.

Very respectfully yours,
W. A. FANNING, M.D.

NINTH AVE., COR. 61ST ST., N. Y., Feb. 19, 1879.

IODOFORMIZED COLLODION (MORETIN).—Dissolve five parts of iodoform in one hundred of collodion. Useful in arthritis and rheumatism.

DEATH OF DR. RANDOLPH MARSHALL.—Dr. Randolph Marshall, Sr., an eminent physician of Cape May county, New Jersey, was found dead in bed at his residence in Tuckahoe, on the night of Wednesday, Feb. 19th. Deceased was 69 years of age.

COLLEGE OF PHYSICIANS AND SURGEONS.—The Seventy-second Annual Commencement of the College of Physicians and Surgeons was held at Steinway Hall on the evening of February 28, 1879. The hall was filled to overflowing. The music was furnished by Grafulla's Band. The exercises were opened by prayer by Rev. Sullivan H. Weston, D.D., after which President Burnard, of Columbia College, administered the Hippocratic oath to the graduating class. The degree of Doctor of Medicine was then conferred upon the *ninety-five* graduates by Prof. Alonzo Clark, M.D., President of the Medical Faculty. The announcement of the prizes was made by Prof. T. M. Markoe, who stated that none of the essays received were sufficiently meritorious to receive the Stevens' triennial prize. The subjects for that prize for 1882 were "Lesions of the Brain" and "Diphtheria in its Relations to Membranous Croup." The prize is open to universal competition. The Joseph Mather Smith prize of \$100, open to the Alumni, was awarded to Dr. William O. Moore, of the class of 1872. The *first* Harsen prize of \$150, for the best report of clinical studies in the New York Hospital for any four consecutive months in the year, was awarded to Frederick M. Brown; the *second*, \$50, to C. Hart Merriam; and the *third*, \$25, to Wisner R. Townsend. Prof. Wm. H. Draper announced that six essays had been received for the Alumni prize of \$500. Of those four were excellent, but neither was regarded sufficiently worthy to become a "substantial contribution to medical knowledge," and therefore no award was made. The prize will remain open for competition until 1880. Prof. John G. Curtis then announced three prizes of \$100, \$50,

and \$25, respectively, for the best public examinations sustained among ten members of the graduating class entitled by efficiency to compete therefor. The *first* prize was awarded to John Ward Hopper, A.B., of New Jersey; the *second*, to John Bernard McMahon, A.M., of New York; the *third*, to Theodore Wellington Corwin, of New Jersey. Three prizes of \$500, \$300, and \$200, respectively, will be awarded next year from the accumulated Dr. Jacob Harsen prize fund to the three of the ten members of the graduating class who are entitled by high proficiency to enter for competition. The valedictory address was delivered by Dr. William F. Wright. The address to the graduates was delivered by Rev. Roswell D. Hitchcock, D.D. It was pithy, and contained much sound advice. Said the speaker:

"Just now I am convinced we are making too many doctors, such as they are; too many lawyers, such as they are; too many ministers, such as they are. I know that no profession is crowded—in its upper parts, but too much crowding at the bottom hurts the top, so that candidates for the higher ranks are fewer, if not inferior. I ask you is your profession yielding its proper proportion of great authors and practitioners and discoverers? I am better acquainted with the others, and I know that the legal profession does not yield its proper proportion of great jurists and statesmen, or the clerical profession its proper proportion of great preachers and theologians. Our educational system, I am constrained to say, is seriously defective in this respect." Dr. Hitchcock thought that if some of our professional schools would die the gain would be great. The next best thing was to establish a system of rigid, merciless examination. If the gain was temporary, it would prove the wisdom of such a course; if it was permanent, it would show that it ought to have been adopted long ago.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—The Eighteenth Annual Commencement of the Bellevue Hospital Medical College was held in the Academy of Music on the afternoon of February 27, 1879. The Academy was completely filled. The music was furnished by a grand orchestra under the direction of Dr. Damrosch. The exercises were opened by prayer by Rev. Alfred B. Beach, D.D., Chaplain of the College. The Hippocratic oath was administered to the graduating class by the Chaplain. The President of the Faculty, Prof. Isaac E. Taylor, M.D., then conferred the degree of Doctor in Medicine upon the one hundred and sixty-five members of the graduating class. The prize of \$200, which was offered by Prof. Lewis A. Sayre for the best essay on "The Pathology and Etiology of Pott's Disease," was awarded to Dr. Seth W. Williams, of New Hampshire. The address to the graduates was delivered by Hon. Richard O'Gorman. Among the rounded sentences to which the speaker gave utterance, the following is pregnant with suggestions: "It is superfluous, I trust, to call attention to the need of the utmost secrecy in regard to the private matters that are intrusted to physicians, who indeed may be said to know the ages of all the village belles better than do the family Bibles. Some one has said that every one at forty is either a fool or a physician. The last can be numbered; but the former are beyond computation, and there are doubtless enough to supply graduating classes for ages to come." The valedictory address was delivered by Hubert Hywood, M.D., of N. C., a member of the graduating class. The class dined at DeMunico's in the evening.

ARCHIVES OF MEDICINE, a bi-monthly journal, E. C. SEGUIN, M.D., Editor, 8vo., pp. 112. New York, G. P. Putnam's Sons. Subscription price, \$3.00 per year; single numbers, 60 cents.

This new journal promises to be a very valuable addition to our periodical literature. It is designed to be, in some respects, the continuation of the "Archives of Scientific and Practical Medicine," and of the "American Clinical Lectures," of which the third volume closing the series was issued last December. The scope of the present journal includes original articles on various subjects sufficient to fill over half of each number; an editorial department where topics in scientific and practical medicine will be discussed; reviews of books, etc.; abstracts, translations, etc.; and a case record where short records of cases will be given. The fact that so eminent and thoroughly qualified a person as Dr. Seguin has been secured as editor, ensures all that is promised for this journal; and he has the aid of a most efficient corps of assistants and collaborators. The assistant editors are Drs. T. A. McBride, Matthew D. Mann and L. A. Stimson.

The opening article is by Dr. T. G. Thomas, on "A New Method of Removing Interstitial and Submucous Fibroids of the Uterus," an abstract of which has been published in these columns.

Dr. Mary P. Jacobi gives a "Provisional Report on the Effect of Quinine upon the Cerebral Circulation." From observations and experiments, made with her characteristic scientific precision, she is inclined to the opinion that large doses of quinine in man diminish the cerebral circulation; and that this is due, in part at least, to its effect in increasing the diastole of the heart which causes increased aspiration of blood to the heart, thus unloading the veins. In experiments on rabbits, however, the cerebral circulation did not seem to be much influenced by the drug.

"The Aid which Medical Diagnosis Receives from Recent Discoveries in Microscopy," is the title of a paper by Dr. C. Heitzmann. There is much in the article that is interesting, and its special aim, that of showing the clinical importance of the microscope, is very praiseworthy. The portion devoted to the author's theory, however, that the microscopical condition of the white blood-corpuscle is an accurate measure of the constitutional condition of its possessor, bears somewhat the impress of an imaginative mind.

The first of a series of "Elementary Lessons in Electricity," is given by A. Floyd Delafield, A.B., in a clear and systematic manner.

In the editorial department, Dr. Seguin discusses the present aspect of the question of tetanoid paraplegia, an affection characterized by impairment of the functions of the lower extremities without loss of power in those parts, a paralysis with rigidity and contractions. This affection was first described by Dr. Seguin, and it is to his credit that his earliest views of the disease appear to be still essentially the true ones, although much has lately been added by the French and Germans.

The articles above given are carefully prepared and clearly written. They will be interesting alike to specialist and general practitioner, with both of whom this periodical deserves to become popular. The journal is elegantly printed on fine, heavy paper, and presents a very attractive appearance.

DEATH OF JOHN HUGH McQUILLEN, M.D., OF PHILADELPHIA.—Dr. John Hugh McQuillen, the Dean of the Faculty of the Philadelphia Dental College, died suddenly in that city on Monday morning, March 3d,

of disease of the heart. He was born in Philadelphia on February 12, 1826, and received his early education in the Friends' school. When he reached his majority he began the study of medicine and dentistry, and entered upon the practice of the latter in 1849. In 1852 he received the degree of M.D. from Jefferson Medical College. In 1857 he accepted the chair of operative dentistry and dental philosophy in the Pennsylvania Dental College, a position which he held until 1862. In 1859 he became editor of the *Dental Cosmos*, a monthly journal recognized as the organ of the profession. He contributed original matter to each number of the magazine, and his papers attracted marked attention. In 1862 he resigned his professorship in the Pennsylvania Dental College, and in the following year made application to the Legislature for a charter for a new dental college, to be styled the Philadelphia Dental College. The enterprise met with much opposition; the charter was, however, granted, and the following fall the college was started and lectures begun. Within the space of ten years the institution grew from a local to a cosmopolitan school. Dr. McQuillen was Dean of the Faculty, and occupied the chair of philosophy. He had been President of the American Dental Association, of the Pennsylvania State Dental Association, and of the Odontographic Society of Pennsylvania.

INDEX MEDICUS.—A monthly classified Record of the Current Medical Literature of the World, compiled under the supervision of Dr. John S. Billings, U.S.A., and Dr. Robert Fletcher, M.R.C.S., England. New York: F. Leypoldt, 37 Park Row. Subscription, \$3 per annum, Vol. I., No. 1.

A MEDICAL journal is as much a necessity to the physician as the trade and stock list is to the man of business, or daily paper to the gentleman of leisure. He who shuts himself out from news of the day becomes narrow-minded and bigoted. A knowledge of the advances in medical science is to be obtained from the medical journals rather than from systematic practice. It is with pleasure that we notice a new periodical, the *Index Medicus*, compiled under the supervision of Dr. John S. Billings, U.S.A., and Dr. Robert Fletcher, Librarian of the Surgeon-General's Office, England. The reputation of the editors is a guarantee of the thoroughness of the work. It will be issued monthly, and will record the titles of all new publications in medicine, surgery, and the collateral branches received during the preceding month. These will be classed under sequel headings, and will be followed by the titles of valuable original articles upon the same subject found during the like period, in medical journals and transactions of medical societies. At the close of each yearly volume, a double index of authors, and subjects will be added, forming a complete bibliography of medicine for the preceding year. We do not see how any one can afford to be without this journal. It is a necessity, and we bespeak for it a hearty welcome, not only from those who are teachers, but from the busy practitioner everywhere.

UNION IN UNUNITED FRACTURE.—A portion of a dog's bone was recently used in procuring union in a case of ununited fracture reported to the *London Lancet* (Oct. 19th), by Dr. Alexander Patterson.

THE REMEDIAL AND FATAL EFFECTS OF CHLORATE OF POTASSA.

By A. JACOBI, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE COLLEGE OF
PHYSICIANS AND SURGEONS, NEW YORK.

(Read before the Medical Society of the State of New York, Feb. 5,
1879.)

CHLORATE of potassa has been used in chemistry to develop oxygen. This appears to have been a sufficient reason for Simpson to recommend its use in habitual abortion, such as depended upon placentitis and insufficient supply, on the part of the fetus, with oxygen.

It appears, also, that it is used for disinfecting ulcerations, having been recommended for that purpose for the same reasons. Now it is true that it changes the color of the blood, but the redness produced by it is no more intense than that which follows the mixture of blood with other alkalies.

It is further true that warm pus will reduce chlorate of potassa, but the same may be found to be true of other epithelial cells.

But many years ago Isambert and Hirne found chlorate of potassa eliminated without any change, and in large quantities, even as much as ninety-five or ninety-nine per cent. of the amount administered, in the various secretions of the body; that is, in the urine, the saliva, the tears, the perspiration, the bile, and now and then even in the milk; no oxygen was developed at all. In the mucous membrane of the respiratory organs it has also been found by Laborde. Thus, while the theory of Simpson was long ago given up, and while it was found that other alkalies would act just as well, and even better in cases of chronic placentitis and habitual abortion, it is just as true that chlorate of potassa holds a higher rank as a remedy in the treatment of certain not unimportant morbid affections.

Its principal value consists in its effect upon catarrhal and follicular stomatitis; further, in mercurial stomatitis, the former being a frequent and the latter a rare disease in infancy and childhood.

In the adult we have many opportunities to administer chlorate of potassa for the purpose of either relieving or preventing mercurial stomatitis. Infants and children, however, bear the use of mercurial preparations a great deal better than adults, at least as far as the local effect upon the cavity of the mouth is concerned. Infants show the local effect of mercury but very rarely, and even children two or three years of age will take mercury for some time before the slightest appreciable symptoms make their appearance upon the gums; even the external use of the oleate of mercury affects their gums but slowly. Thus, while there appears to be no necessity for the use of chlorate of potassa in these cases, still it is desirable not to neglect, at least, its local application whenever mercury is to be given for a certain period.

The other forms of stomatitis do not require nor indicate the use of chlorate of potassa to the same degree as the two forms above mentioned. For instance, the infectious stomatitis of the new-born and young infants, the so-called thrush or sprue, will, it is true, do well under the use of chlorate of potassa, but it will do well also, and almost as well, under the use of water only, or of salt and water, and still better

under the local application of a solution of borax, (without sugar, or syrup, or honey), which destroys parasitic fungi more rapidly.

Diphtheritic angina is one of the forms of stomatitis and pharyngitis in which chlorate of potassa has been used extensively, but we shall find that it is not indicated, though on the same principles, to the same degree as in the other forms. It has also been used in catarrhal forms of ozæna, either by means of injections or other local applications. Further, it has been used in the treatment of toothache dependent upon caries.

In all of these cases I should recommend that it be given in plain solution in water, with no addition whatsoever, except, perhaps, glycerine. But not only the upper portion of the alimentary canal has been found, or believed to be benefited by the administration of chlorate of potassa, but in the opinion of a small number of authors, its use is indicated in catarrh of the intestinal tract. Bonfigli has even gone further. He recommends chlorate of potassa as a reliable remedy in the treatment of diarrhoea of infants depending upon vascular paralysis. He believes that he has seen favorable effects follow the administration of the remedy continued for one single day. He asserts that he has found improvement after its administration, relapse when the remedy was discontinued, and improvement again when the administration was renewed. He insists upon the use of large doses whenever there is intense depression of the general nervous system; for he assumes in those cases that fatty and amyloid degeneration of the walls of the blood-vessels, or extravasations and ulcerations of the walls of the intestines, have made their appearance. I have referred to his statements so fully in order to give at least one of the millions of instances in which the individual judgment is biased, and medical progress is liable to be thwarted by enthusiasm, not complicated with reason. Even the mucous membrane of the genito-urinary tract has been believed to be favorably influenced by chlorate of potassa. Edlefsen administers the remedy both internally and externally in cases of catarrh of the bladder, and in large doses.

He believes that he has seen favorable results, and insists upon the innocuousness of the remedy which, according to him, is proved by a large experience. I may add, at once, that my own experience in the administration of chlorate of potassa in vesical catarrh has given no favorable results whatsoever; and although taking Edlefsen's results as facts, there are certainly other facts which seem to contraindicate the use of chlorate of potassa in just such cases.

My own position in relation to chlorate of potassa, when given in catarrhal and follicular stomatitis, I have stated above. In regard to diphtheria, I can give it in a few words (as I have referred to the same subject on former occasions, and particularly in my contributions to the pathology and treatment of diphtheria). It is this: that chlorate of potassa is a valuable remedy in diphtheria, but that it is not *the* remedy for diphtheria. There are very few cases of diphtheria which do not exhibit larger surfaces of either pharyngitis or stomatitis than of diphtheritic exudation. There are also a number of cases of stomatitis and pharyngitis, during every epidemic of diphtheria, which must be referred to the epidemic, perhaps as introductory stages, but which still do not show the characteristic symptoms of the disease.

When, in 1860, I wrote my first paper upon diphtheria, I based it upon two hundred genuine cases, and at the same time enumerated one hundred and

eighty-five cases of pharyngitis, which I considered to be brought on by epidemic influences, but which, the membrane being absent, could not be classified as *bona fide* cases of diphtheria.

Such cases of pharyngitis and stomatitis, no matter whether under the influence of an epidemic or not, furnish an indication for the use of chlorate of potassa. They will get well with this treatment alone. The cases of genuine diphtheria complicated with a great deal of stomatitis and pharyngitis also indicate the use of chlorate of potassa; not as a remedy for the diphtheria, but as a remedy for the accompanying catarrhal condition in the neighborhood of the diphtheritic exudation. For, it is a fact that, as long as the parts in the neighborhood of the diphtheritic exudation are in a healthy condition, there is but little danger of the disease spreading over the surface. Whenever the neighboring surface is affected with catarrh, or inflammation, or injury, so that the epithelium is loose or removed, the diphtheritic exudation will spread within a very short time. Thus chlorate of potassa or soda, which is more soluble and more easily digested than the former, will act as a preventive rather than as a curative remedy. Therefore it is, that common cases of pharyngeal diphtheria will recover under this treatment alone, nothing else being required.

The cases of diphtheria in which the exudation is limited to the tonsils are by no means dangerous, for the lymphatic communication between the tonsils and the rest of the body is none at all, or very trifling. Thus no absorption into the circulation can take place from a tonsillar diphtheritis alone. The surrounding stomatitis and pharyngitis will be favorably influenced by the administration of chlorate of potassa or soda, and thus the entire disease will run a favorable course, inasmuch as the tonsillar exudation will be removed within three or six days. The surrounding portions of the mouth and fauces in the meanwhile being put into a tolerably healthy condition, the danger is passed. These are the cases which have given the reputation to chlorate of potassa as a remedy for diphtheria.

The dose of chlorate of potassa for a child two or three years old should not be larger than half a drachm (2 grammes) in twenty-four hours. A baby of one year or less should not take more than one scruple (1½ grammes) a day. The dose for an adult should not be more than a drachm and one-half, or at most two drachms (6 or 8 grammes), in the course of the twenty-four hours.

The effect of the chlorate of potassa is partly a general and partly a local one.

The general effect might be obtained by the use of occasional larger doses; but it is better not to strain the eliminating powers of the system. The local effect, however, cannot be obtained with occasional doses, but only by doses so frequently repeated that the remedy is in almost constant contact with the diseased surface. Thus the doses, to produce the local effect, should be very small and frequently administered. It is better that the daily quantity of twenty grains should be given in fifty or sixty doses than in eight or ten; that is, the solution should be weak, and a drachm or half a drachm of such solution can be given every hour or every half-hour, or every fifteen or twenty minutes, care being taken that no water is given soon after the remedy has been administered, for obvious reasons.

I have referred to these facts with so much emphasis because of late an attempt has been made to introduce chlorate of potassa as the main remedy in bad

cases of diphtheria—and, what is worse, in large doses.

It is Seeligmüller who has especially recommended chlorate of potassa for that purpose in a saturated solution. Sachse also looks upon a saturated solution of chlorate of potassa as a panacea, inasmuch as he did not lose a case out of one hundred, except those, as he says, "which were hopeless at the beginning." A young colleague in our State also recommends chlorate of potassa (six drachms daily) as his sheet anchor in diphtheria (LOUIS WEIGERT, M.D., *Hospit. Gaz.*, Jan. 16, 1879).

Seeligmüller administers a solution of one to twenty. Of this he gives children of three years and over a tablespoonful every hour at first—doses which amount to half an ounce in twenty-four hours; afterward every two or three hours. To children a little younger he gives half a tablespoonful, and continues the treatment day and night. He insists upon the necessity of not adding any syrup to the solution, and also of not allowing the patient to drink within a short time after the administration of the remedy. In his opinion the internal treatment suffices; still he advises that the solution should be used as a wash, a gargle, and also should be snuffed.

He says that the bad odor and fever, under that treatment, disappear within a very short time. The number of cases which he first reported as treated successfully in this manner was fifteen. At the same time he gave milk, broth, egg, and a small quantity of Tokay wine. These cases were published a number of years ago. Since that time he has modified his opinion to a certain extent. He says that chlorate of potassa may prove injurious, because of the possibility of the potassa acting upon the heart; and that, when it does, the heart's action becomes either more or less frequent, and may be intermittent. On the other hand he directs attention to the fact that diphtheria itself will act upon the heart in a similar way; and, as soon as such symptoms occur, quinine, coffee, and wine are recommended.

Digestion may also be interfered with by chlorate of potassa, inasmuch as when acute gastric catarrh is present the remedy is not well tolerated. In such cases smaller quantities must be given, or the drug must be discontinued altogether. In consequence of finding these drawbacks, he insists upon the above method of administering the remedy only during the first twenty-four or thirty-six hours. This modification he began particularly after a few of his patients died with a sensation of burning and soreness.

I have reported his practice so extensively, because I mean to raise my voice against it for the reason of its dangerousness.

As early as 1860, I advised strongly against the use of large doses of chlorate of potassa, but the translation of the paper I then published in the *American Medical Times*, which was printed in the *Journal fuer Kinderkrankheiten*, in 1861, was so defective, that I am not astonished at my warnings having been overlooked on the European side of the Atlantic. The treatment is dangerous, because of the largeness of the doses of the chlorate of potassa given.

Seeligmüller himself reports a case of a boy six years of age, who died within a very short time under the chlorate of potassa treatment, the main symptoms being copious greenish discharges, obstinate vomiting, and collapse. The kidneys were not examined after death, but the symptoms and the resemblance of these cases to a number of others of equal nature and result, prove them to be cases of nephritis depending upon over-doses of chlorate of potassa.

Lacombe had under observation a man who took one ounce of chlorate of potassa, intending to take an ounce of the sulphate of magnesia. The man died in convulsions, after having purged very freely, and the cause of death was regarded as *excessive diarrhoea*. The probability is that it was a case of nephritis.

Isambert, in his first reports upon the effects of chlorate of potassa, published more than twenty years ago, found among its effects increased diuresis, a sensation of heaviness and dragging in the lumbar region, such as is found after the administration of large doses of nitrate of potassa.

Ferris reports a case of death from cyanosis, with absence of pulse, within a period of thirty-six hours after taking a tablespoonful of the chlorate of potassa.

He found the ventricles of the heart empty and contracted, while the auricles were distended with dark blood. The kidneys were not examined.

When I myself, nearly twenty years ago, took single half-ounce and six-drachm doses of chlorate of potassa, I had a sensation of heaviness and dragging in the lumbar region, and increased renal secretion. I did not examine for albumen.

The case of Dr. Fountain, of Davenport, Iowa, occurring at the very same time, is well known. He experimented upon himself, taking over an ounce of the chlorate of potassa, and died within four days of nephritis.

A case of death from chlorate of potassa, occurring in the practice of Dr. Krackowizer, I reported some years ago. It was that of a young lady who was told to use a solution of one ounce of chlorate of potassa as a mouth-wash and gargle. Instead of that, she swallowed the whole of the solution, and within three days died of nephritis.

I have also, before this, referred to one of my own cases; it was that of a man of thirty-odd years, who was told to use internally ten drachms of the chlorate of soda, within six days. Instead of that he took the entire quantity within six hours. Within twenty-four hours he suffered from diffuse nephritis. What little urine he passed was smoke colored, and afterward black. It contained a large percentage of albumen, blood, hyaline and granular casts. Then there was complete suppression. There was vomiting and diarrhoea, headaches, and coma. He died upon the fourth day, and the post-mortem examination exhibited acute diffuse nephritis.

Dr. J. LEWIS SMITH, in a meeting in which the above statements of mine were referred to; reports a case of a child three or four years of age (See MEDICAL RECORD, p. 397, 1878), who took three drachms of the chlorate of potassa in one day. After that only a few drops of bloody urine were discharged, and the child died at the end of twenty-four hours.

In the same number of the same journal Dr. Hall reports a case of a child under one year of age, who took one drachm of the chlorate of potassa in a single night, and with exactly the same symptoms and the same results.

Conrad Küster (D. Zeitsch. f. prakt. Med., 1877, No. 33), for no other purpose but to prove the essential identity of punctated, maculated, membranaceous, croupous, and nephritic forms of diphtheria—similarly to most writers since Bard, Bretonneau, and myself amongst many—reports the following cases:

A young woman of twenty, vigorous and blooming. Mild angina. Small, white specks on tonsils. Feels pretty good. A strong solution of chlorate of potassa for gargling and internal administration. No doses, however, reported. The doctor found her dying at daybreak the following morning. Relatives said that

vomiting and diarrhoea commenced in the evening, but that they all slept and were awakened in the morning by the laborious breathing of the patient. No post-mortem examination was made; urine was not obtained. There was no dropsy, but the skin exhibited a peculiar husky hue.

A man of thirty, in vigorous health. Trifling maculated diphtheritic angina. Strong solution of chlorate of potassa as a gargle and internally lime-water, besides. The tonsils cleared rapidly, but some malaise all the time. Urine albuminous. The doctor learned that the urine was peculiarly black on the third or fourth day. Gradual improvement, but urine albuminous a year and a half after.

A boy of three years, in good health; very mild, punctated, diphtheritic angina. Two other children had diphtheria seriously half a year previously, one of which died of laryngeal diphtheria. Gargle and administration of a strong solution of chlorate of potassa. Next day the doctor was notified the child was dying, and had passed black urine. So it was. The urine *was* black, a little greenish hue, moderately albuminous, the surface bluish white, the child dying. A good deal of vomiting. No dropsy. No post-mortem.

A girl of four, also robust and vigorous. Mild angina, some trifling whitish marks, hardly visible in the tonsils. Gargles and administrations of chlorate of potassa in strong solution. Appears nearly well, both locally and generally, within two days. But in the afternoon very suddenly vomiting, yawning, apathy, bluish-white complexion, accelerated compressible pulse, skin cool. In the evening some urine, black with greenish hue, albuminous, contained hematine. On the following days the color became more normal, and albumen less. On the fifth day the danger was over, but the pulse remained frequent a long time. No dropsy. A slight return of albumen on the sixteenth day.

Now Dr. Küster claims all of these cases as acute nephritis, and adds verbatim: "There is here a peculiar resemblance to renal irritation in carbolic acid poisoning. One is reminded of a medicinal poisoning, and would presume its presence if *carbolic acid* had been used for external application. In my cases the substance irritating the kidneys could be *none but the chlorate of potassa*. However, as this effect of chlorate of potassa has not been observed, as nephritis in diphtheria is, besides, nothing unusual, the latter must be claimed as the cause of the accidents."

Küster's facts are correct, his theory is not. His cases were mild, all of them tonsillar, no general symptoms, no adenitis; in fact there is no, or very little, lymph-vessel communication between the tonsils and the rest of the body. Two of his four cases terminated fatally in a very short time; two barely escaped. The same symptoms, the same nature of the disease in all. The cases seemed to the author like so many of poisoning by medication, *and so they were*. Unfortunately the author, otherwise known as careful, earnest, and conscientious, reports no doses, but in every case he speaks of *strong* solutions of chlorate of potassa, which appear to have been used rather indifferently or indiscriminately. If you have followed my remarks, and compare my own cases with his, and if I remember how deeply impressed many of my professional brethren were when I first mentioned my experience in public and in print, all of us will not hesitate to look upon his cases as such, of acute nephritis brought on by excessive doses of chlorate of potassa.

After all the previous remarks, the practical point I

wish to make is this, that chlorate of potassa is by no means an indifferent remedy; that it can prove, and has proved dangerous and fatal in a number of instances, producing one of the most dangerous diseases—acute nephritis. We are not very careful in regard to the doses of alkalis in general, but in regard to the chlorate we ought to be very particular. The more so as the drug, from its well-known either authentic or alleged effects, has risen, or descended, into the ranks of popular medicines. Chlorate of potassa or soda is used perhaps more than any other drug I am aware of. Its doses in domestic administration are not weighed but estimated; it is not bought by the drachm or ounce, but the ten or twenty cents worth. It is given indiscriminately to young and old, for days or even weeks, for the public are more given to *taking hold* of a remedy than to *heed warnings*, and the profession are no better in many respects. Besides, it has appeared to me, acute nephritis is a much more frequent occurrence now than it was twenty years ago. Chronic nephritis is certainly met with much oftener than formerly, and I know that many a death certificate ought to bear the inscription of nephritis instead of meningitis, convulsions, or acute pulmonary oedema. Why is that? Partly, assuredly, because for twenty years past diphtheria has given rise to numerous cases of nephritis; partly, however, I am afraid, because of the recklessness with which chlorate of potassa has become a popular remedy. Having often met medical men unaware of the possible dangers connected with the indiscriminate use of chlorate of potassa or soda, I thought this Society would excuse my bringing up this subject. It may appear trifling, but you who deal with individual lives, which often are lost or recovered by trifles, will understand that I was anxious to impress the dangers of an important and popular drug on my colleagues, and through them on the public at large.

CONCLUSIONS FROM THE STUDY OF ONE HUNDRED AND TWENTY-FIVE CASES OF WRITER'S CRAMP AND ALLIED AFFECTIONS.

By GEORGE M. BEARD, M.D.,

NEW YORK.

(Read before the Medical Society of the State of New York, Feb. 5, 1879.)

DURING the past few years I have been specially investigating the disease known as *writer's cramp* and affections allied to it, as *telegrapher's cramp*, *musician's cramp*, and the *cramp of sewing-women*, and others engaged in occupations that draw so severely and exclusively on certain muscles as to induce weakness of those muscles and of the nerves that supply them.

These investigations have been pursued in various ways—by the study of cases in my practice; by conversation and correspondence with physicians from all parts of the country and other countries; by consultation with physicians in regard to cases, and by circulars of inquiry that have been noticed in various journals and brought to the attention both of physicians and the sufferers from the disease. The inquiry has extended to England, Germany, and Australia.

The conclusions at which I have arrived, stated in the most condensed manner possible, are as follows. I present the results without argument or discussion, reserving the details for a subsequent occasion, and shall here confine myself to those facts that are more

or less novel and unfamiliar, and of the greatest scientific and practical interest.

The main results can be stated in these eight propositions:

First.—*What is called the cramp is but one of a large number of the symptoms of this disease, and no two cases are precisely alike.*

There are at least fifteen or twenty other symptoms of this disease. The recognition of these symptoms, especially in the early and premonitory stage, is of the highest moment, for the reason that in the early stage the disease is curable.

The cramp in those cases, where it appears, is oftentimes one of the later symptoms, and bears much the same relation to the disease that the symptoms of the ataxia gait bears to the disease locomotor ataxy. *In some cases there is no cramp from first to last, and in all cases the cramp is preceded or accompanied by other symptoms.*

The list of symptoms of writer's cramp is as follows: 1, *Fatigue, exhaustion*; 2, *dull, aching pain*; 3, *nervous, irritable feeling*; *general nervousness*; 4, *trembling, unsteadiness*; 5, *cramp, spasm, jumping, twitching, rigidity, contraction of muscles* (in some cases the pen is involuntarily hurled at a great distance, as across the room); 6, *stiffness and tightness*; 7, *powerlessness, helplessness*; 8, *numbness, areas of anesthesia, tingling*; 9, *neuralgia*; 10, *burning, stinging, dancing, prickly feeling*; 11, *soreness*; 12, *throbbing and swelling feeling*; 13, *thrilling, running, electric sensations*; 14, *tightly-bound feeling of wrist*; 15, *coldness*; 16, *abnormal sensitiveness to touch or cold, or mental influences*; 17, *disinclination to write*; 18, *slowness in writing*; 19, *itching*; 20, *perspiration*; 21, *temporary aphasia*; 22, *dryness of the joints*; 23, *swelling of the wrist and hand*; 24, *actual paralysis*; 25, *abnormal grasp of the fingers on the pen-holder or pencil—a very common symptom; tendency of the fingers, especially the middle one, to slip out of their places on the pen-holder, creating a desire by the sufferer to moisten them to prevent slipping; bearing down on the paper with unnatural or unusual pressure.*

Many of the above symptoms are not confined to the hand, but extend to the forearm, arm, shoulder, neck, to the opposite arm, and over the whole body. It is clear, therefore, that the term *writer's cramp* is the worst possible misnomer, and that the disease has been most imperfectly understood in medical literature. It is wise, however, to retain the term both in scientific and popular circles, for in the prospective state of our knowledge no term capable of including precisely and exhaustively all the phenomena of the disease can be suggested. When any disease is designated by a term that is at once short, familiar, and easily retained, it is not well, as a rule, to attempt to displace it. To name diseases from prominent and special symptoms, and real or suspected factors in their causation is, during certain stages of medical progress, both natural and inevitable, as is illustrated by hay-fever, epilepsy, hysteria, insanity, neuralgia; and to attempt to substitute terms based on imperfect and changing knowledge of pathology, is to heighten the confusion that we would remove.

Secondly.—*Also in the other forms of professional cramp, as that of telegraphers, musicians (violonists, organists, pianists, harpists), sewing-women, painters, artists, dancers, hammer-palsy, and so forth, the cramp is but one of a number of symptoms, and by no means always the most important symptom; and, as in writer's cramp, there is frequently no cramp at all, from the beginning to the end of the disease.*

There is no *one* symptom of the disease that can be said to be diagnostic. It is by taking a survey of all these symptoms, and by studying them in their relation to each other and to the history of the case that we are able to make out the diagnosis of writer's cramp, or of any of these allied disorders. This rule applies to the entire nervous system; there is not a disease known to neurology that can always be diagnosed by any single symptom; all the familiar disorders of the brain, of the spinal cord, or of the peripheral nerves are studied not through isolated phenomena, but through groups of phenomena, acting and reacting on each other; pathognomonic symptoms belong to lecture-rooms and text-books, not to practical experience.* An analogous disease, that has not been described, is the *counting-money cramp*, from which a lady-clerk in the Treasury Department at Washington once suffered; it is caused by excessive and restricted use of the fingers in handling bills.

Thirdly.—This disease is primarily a peripheral and local disease of the nerves and muscles; secondarily and rarely it becomes central and general, or it may result from various central lesions; and it may affect any point between the extreme periphery and the centre.

This view of the pathology is a compromise between the old view that it was central, and the theory of Poore, of London, that it is purely peripheral.

No two cases are precisely alike in their pathology, but there is no question that in some exceptional cases the disease extends to the centres. That it affects the left hand as well as the right is no proof that the disease is central; it simply develops to the left hand when that hand is used, for the same reason that it affects the right hand.

The theory that writer's cramp is a result of lesion or disturbance of special co-ordinating centres in the brain is not sustained by a single properly-understood fact; on every point it fails to account for and harmonize the phenomena. So far, my own conclusions are in entire accord with those of Dr. Poore, of London, who has investigated this subject most intelligently and successfully.†

In truth, the detailed pathology of writer's cramp is not simple, but complex; in some cases there is neuritis which may affect a single nerve-branch or several nerve-branches, and may be restricted to the fingers and hand, or extend up the forearm and arm; then the muscles may be merely exhausted—chronically fatigued—or with a tendency to spasm and contracture. The worst phase of the disease that I ever saw was in 1874, with Dr. Brodie, of Detroit; in that case the arm was drawn over to the back, and held firmly there by the contracted muscles; the patient was unable to use his hand for any purpose, and also suffered great pain.

In some cases the disease, or rather the tendency to the disease, is hereditary—two and three cases having been known in a single family.

Fourthly.—This disease occurs mostly in those who are of strong, frequently of very strong, constitutions, and is quite rare in the nervous and delicate; and when it does occur in those who are nervous, is easier relieved and cured than when it occurs in the strong.

This fact is not peculiar to writer's cramp, but applies to other nervous diseases, as impotence, muscular atrophy, and ataxy. I see every day cases of nervous exhaustion (neurasthenia) in its various forms, and quite rarely do I see writer's cramp in them; and when they do have this disease, it is mild and curable. I have successfully treated a number of these cases.

Fifthly.—This disease is far less likely to occur in those who do original work, as authors, journalists, composers, than in those who do routine work, as clerks, book-keepers, copyists, agents, and so forth.

The reason is clear. Original thinkers must take time for thinking as they write, and thus they rest the nerves and muscles of the hand; while routinists, having little or no thinking to do, write on constantly and uninterruptedly, oftentimes at the extreme of their speed.

In some cases an attack of writer's cramp has followed a single task of long copying. In one of my cases—an authoress—there had never been any sign of the disease until she performed a task of routine work. Of my cases eight were physicians, eight were lawyers, five were clergymen, and the remainder were clerks, book-keepers, agents, copyists, and merchants.

Men who write bad, scrawly, illegible hands never have writer's cramp; it is the penalty for writing plainly and carefully. Like prevents like, and those who always write as though they had writer's cramp never have it.

Sixthly.—This disease, like all nervous diseases in this country, diminishes in frequency as we go South.

In the Gulf States writer's cramp and maladies allied to it are very rare. The same is true of hay-fever, which is a type of nervous diseases; and, indeed, of the whole family of functional nervous maladies, such as sick-headache and neurasthenia, or nervous exhaustion in all its manifestations.

In investigating this subject I have corresponded and conferred with physicians all through the South. Dr. Bryce, Superintendent of the Alabama Insane Asylum, Tuscaloosa, whose opportunities for observation have been very large, has written me a very interesting letter on this question.

Seventhly.—Writer's cramp is no longer an incurable disease.

In the early and forming stage, especially, it responds to treatment quickly, and in many cases permanently. During the stage of exhaustion, fatigue, and pain, with the other symptoms of numbness, neuralgia, irritability, trembling, powerlessness, soreness, coldness, stiffness, and so forth, this disease can be treated as satisfactorily as almost any other form of nervous disorder; and, even when cramp or spasm of the muscles have appeared, it may be entirely cured.

In the later stages, after the symptoms have existed for years, the malady may become absolutely hopeless, even though the patient abandon his occupation. I have seen cases that have been afflicted for over a quarter of a century.

One striking case of this kind I had opportunity to see through the courtesy of Dr. W. C. Wey, of Elmira, N. Y. Both hands were affected, and the numbness and powerlessness were so marked that sometimes a newspaper that he was reading would drop to the floor. The whole body seemed, indeed, to have been disturbed, and he had been obliged to give up his position as cashier of a bank.

In all these cases, the prognosis is better in nervous and delicate patients than in those who are phlegmatic and strong.

* Ataxy, for example, was formerly diagnosed by inability to stand with closed eyes, by the ataxic gait, and by the electric puffs; and more recently an unsuccessful attempt has been made to prove that the absence of the tendon reflex is a sure sign of that disease. There was no need of experiment to disprove this claim; the physiology and pathology of the nervous system are now in a condition, where we are able to prove deductively—without examination—that all such claims of pathognomonic symptoms, however reliable they may be as aids and accessories, are illogical and unscientific.

† Transactions of the London Medico-Chirurgical Society, vol. IX.

Eighthly and lastly.—The treatment of writer's cramp and affections allied to it consists :

1. In the use of electricity locally applied. Both galvanic and faradic currents may be used—preferably the former. In some cases galvanization of the spine and neck, and what are called spinal-cord nerve-currents, are indicated. Strong galvanic currents, with metallic electrodes, I have used with advantage in some cases where mild currents seemed to do no good. The wire brush with the faradic current I often use, and in some cases electro-puncture.

The relief of pain and fatigue that follows these electrical applications is immediate and uniform, and most grateful to the sufferer; and this temporary effect can be obtained even in the worst cases. I have not yet been able to demonstrate any very marked advantage from the rhythmical movements of the muscles in connection with the electrical applications.

2. Hypodermic injections of atropine, strychnia, duboisia, Fowler's solution, and other tonics, narcotics, and sedatives. These remedies need often to be gradually pushed to their physiological effects. Electricity and hypodermic injections combined have made an epoch in the treatment of writer's cramp. The evil effects of hypodermic injection are guarded against by care in preparing the solutions, by dilution of irritating substances, by moderately deep puncture, and by substituting other treatment in those cases where, from any constitutional tendency, suppuration is easily excited.

3. The internal use of calabar-bean, ergotine, iodoform, and in some cases of nerve-food, as oil and fats. It is useless, in the majority of severe cases, to dally with mild remedies or ordinary tonics.

4. *Massage*, or systematized kneading and manipulation of the muscles, with friction, and pinching, and pounding of the skin, and passive movements of the joints, large and small.

Dr. Douglass Graham, of Boston, has used this method with very encouraging success. I now employ it in all my cases. The whole arm should be treated.

5. The use of dry heat and dry cold, by rubber bags containing hot water or ice. These may be used alternately.

6. The actual cautery and very small blisters to the upper portion of the spine, or along the course of the affected nerves and muscles.

Rest alone, even long abstinence for many months from writing, will not cure writer's cramp, as has been proved by the experience of many cases. The best results I have ever had have been made with cases that kept right along with their occupation—although avoiding excessive work—with the aid of mechanical appliances.

Among the hygienic devices for the relief and cure of writer's cramp are the following :

1. The device for holding the pen—a ring-pen-holder—so as to relieve the thumb and fingers. An excellent arrangement of this kind has been perfected by one of my patients. By this contrivance the thumb is allowed perfect rest, and the index-finger and second finger are united by rings so as to make practically one finger, which is attached to the pen-holder. The over-use of the muscles most liable to be involved in writer's cramp is thus avoided. The gentleman who perfected this *ring-penholder* was himself substantially cured of a bad form of writer's cramp by its use in connection with electrical and other treatment, as above described. He is a book-keeper, and can now follow steadily his occupation, although troubled at times with symptoms of wear-

ness. He kept right on with his occupation during treatment.

2. The type-writer. This instrument is destined to be of great practical service to writer's-cramp sufferers, as well as to those who, though not having the cramp, are made generally nervous and locally tired by the mechanical labor of writing. During the past year I have made many experiments with this instrument, and studied carefully its relations to the nervous system, in order to determine these points. Unfortunately, book-keepers and those who write very short notes or messages and signatures cannot profit by the type-writer; but for those who write continuously the instrument is an almost perfect relief. After some instruction a reasonable degree of skill in its practical use can be obtained during the play-hours of two or three months.

Thurber's kaligraph, now almost forgotten, was an ingenious contrivance for writer's-cramp sufferers; but it is now superseded by the two inventions just noticed.

3. The use of large pen-holders, so that the muscles may be less restricted; fastening a piece of sponge to the penholder, so as to relieve the pressure of the fingers. One of my correspondents writes me that he used this device for a year.

4. Holding the pen between the different fingers, thus relieving the thumb and index-finger. One of my medical friends finds great relief by this device.

5. The use of quills and very flexible pens, and pens with very broad points, so as to run easily like quills. Some pens have been sent to me from Germany that are made with this special object in view. The use of the lead-pencil is also a great relief. The mica pen and the Esterbrook stub-pen are worthy of trial.

6. Frequently changing the pen and the penholder and style of pen, so as to change the mode of action of the muscle. Dipping the pen for ink is usually regarded as an evil, but it doubtless saves many of us from writer's cramp.

7. Changing the position in writing, as from sitting to standing, or holding the paper in the lap. These methods of relief are to be commended, especially for those who are just beginning to have the symptoms of the disease, who are yet in the stage of exhaustion. It is a mistake to always try to point the pen toward the right shoulder. When utterly tired out, it is well to stop entirely.

8. The avoidance of faulty and painful methods of writing, and the study of easy, natural methods. A person who writes a cramped and stiff style, no matter though it be a legible one, is a fair subject for attack, especially if writing occupies most of the time. This factor is of great importance. An eminent author and journalist is accustomed to put his pen in the penholder at an angle of several degrees backward, and thus is able, as he tells me, to write consecutively over forty words a minute.

9. Writing with the left hand. Out of 18 cases that tried this plan, 3 failed utterly, 6 were partially successful, and 9 were completely successful. In the 6 partially successful cases the disease either appeared in the left hand, or after a time showed a tendency to appear there. At the beginning of the disease, educating the left hand may be of itself sufficient for a cure.

10. The use of various gymnastic and athletic exercises, as rowing, paddling, and so forth. In some cases the sufferers are unable to do many other kinds of work; carrying bundles or turning door-knobs hurts them just as writing does; but such cases are exceptions.

Speed of Handwriting.—In the study of this subject, I have made many experiments with a view to determine the average speed of handwriting. I find that between twenty-five and fifty words are written in a minute by those who are accustomed to write, the average being perhaps about thirty words when no time is lost in thinking or dipping the pen.

The method of experimenting that I have adopted is, to have the subject experimented on write something with which he is quite familiar—words of all lengths—for one minute. Practically, no one writes steadily as fast as these experiments would indicate, for, after a few moments of writing at the very top of speed, there will come to the majority a weariness; then the delay of composition also interferes.

These experiments were made with lawyers, physicians, clerks, book-keepers, scientists, and men of letters. Mr. T. A. Edison, the inventor, is also an expert in handwriting, and I have made with him a number of experiments in order to test the rate of speed of different varieties of penmanship. When he writes slowly and with care—from fifteen to twenty-five words a minute—Mr. Edison's handwriting is phenomenally clear and beautiful, resembling copperplate printing; not in a flowing, but in a cramped hand, the letters being often separated as in print. When he rises to forty words a minute, the writing is still more cramped and less beautiful, though yet legible; with forty-nine words a minute, his writing is quite illegible.

I find that journalists write with a lead-pencil—which, as a class, they generally use—from forty to fifty words a minute. Experts on the type-writer, according to my experiments, can print for a short time at dictation from seventy-five to one hundred words a minute; but in practice, very few of those who use the instrument put down on the average more than half that number.

A number of years ago a man attempted on a wager to make with a pen an enormous number of up and down strokes—a million, I believe, within a month or less time. Swelling of the hand and wrist, with severe pain, so annoyed the experimenter that it was necessary for some one to stand near him and pour on cold water and apply various lotions. In this cramped and continuous movement and tension of muscles is found the philosophy of all these forms of professional cramp. I have made some experiments with myself in order to ascertain just how many single disconnected up and down strokes I could make with a pen; and find that from 175 to 200 a minute is about the limit, and very soon the hand becomes wearied. A friend of mine, connected with the Surgeon's office in this city, tells me that the clerks in that department sometimes complain of swelling of the wrist from over-writing.

Mr. Edison, whose amazingly fertile mind is constantly making original suggestions even in departments quite remote from his own, showed me not long ago the following fundamental experiment. A small rod of steel or iron, or other hard substance, about one-third of an inch in diameter, is held very firmly between the thumb and forefinger of the left hand; very soon there comes a pain in the adductor of the thumb, which may be unbearable. This position is a familiar one to manufacturers of electrical apparatus, since it represents their method of winding wire on bobbins.

Telegrapher's and Musician's Cramp.—The above practical conclusions in regard to treatment apply to the other forms of professional cramp, as that of telegraphers and musicians—violinists, organists, pia-

nists, and harpists; also to the cramp of artists, painters, engravers, and sewing women.

Telegraphic operators have two forms of cramp—the ordinary writer's cramp, from receiving and writing out messages; and true telegrapher's cramp, from striking the index-finger on the sending instrument. The malady is quite a common one among telegraphers; and an attempt has been made to reduce its frequency by the use of a rubber cap on the button on which the finger presses in sending. This device is, I understand, but partially successful.

Musicians, when afflicted with cramp, have the same symptoms as writers, and are likely to suffer in both hands, although one hand may be affected quite differently from the other. In one case that I saw through the courtesy of Dr. Webber, the right hand, on beginning to play, showed contraction of the muscles of the thumb and index-finger, with a tendency upward; while in the left hand, at the same time, the second and third finger were firmly flexed into the hollow of the hand, so that they could be opened only with great difficulty. In a case now under my care, the right hand is affected in precisely the same way, while in the left hand the little finger only is disturbed. This form of trouble often comes from stretching the hand in playing octaves.

In another case the third finger of the right hand is raised involuntarily while playing; and in an organist now under my care there is simply stiffness and pain in the interossei between the third and little finger, and anesthesia of the back of the hand. In the case of a very eminent violinist the muscles of the left arm and forearm, and also the fingers, were so weak and exhausted from long holding the violin in position, that he had to abandon his profession.

I have succeeded in curing a long-standing case of pianist's cramp, where the symptoms seemed to depend on a neuritis, excited originally by exposure to cold in bathing, and made worse by severe practice at the piano. In this case there had been great uneasiness, and even severe pain after playing, and he had abandoned his profession. He is now able to play several consecutive hours without fatigue.

THE ECCENTRIC GENUCLAST.

By C. FAYETTE TAYLOR, M.D.,

NEW YORK.

WHATEVER practical value the "new osteoclast" * may ultimately prove to possess, in affording a more simple solution of certain questions growing out of distortions after unarrested coxitis, or in shortening after fractures instead of osteotomy, its employment must, necessarily, be somewhat restricted for the want of appropriate subjects. But it has long been felt that there was a necessity for a practicable genuclast, and that an instrument for reducing flexions, overcoming contractions and breaking up osseous and fibrous adhesions at the knee-joint, if at once simple and adaptable, would be a boon to the profession. We are continually meeting with cases of simple contraction of the hamstring muscles, which, with our present means, can only be reduced after tenotomy, because these muscles are too strong to be overcome, with practicable force; or where the stretching cannot be repeated often enough to accomplish permanent results, without so many annoying difficulties as to

* Exhibited to the New York Academy of Medicine, April 5, 1877, and published in the MEDICAL RECORD for April 21, 1877, the *new osteoclast* differs from its predecessors in its capability to localize, with certainty, the seat of the fracture which it makes.

amount to a preclusion of the operation, in cases where it is plainly indicated. Again, there are many cases of commencing adhesions between the articulating surfaces, which, it would seem possible to prevent from progressing to ankylosis, if we possessed the means for breaking them up without, at the same time, seriously injuring the joint, in the necessity we have been under of making it the fulcrum of the force applied. So that the surgeon has been obliged to wait for the joint-inflammation to fully subside before operating, thus giving time for the adhesions to become firm and osseous deposits to take place, as well as necessitating the use of much greater force in the operation than would have been required if the same thing could have been done at an earlier stage of the reparative movement, without relighting an inflammation. The crude and unhandy way in which ankylosis at the knee-joint has hitherto been broken down, when anything at all has been attempted, has been enough to deter surgeons from operating as often as it, no doubt, might profitably be done with a well-constructed genuclast.

The want of such an instrument was forcibly impressed on my mind, several years ago, when I was called to a case of flexion at the knee-joints, which

condition of the muscles from inaction. There was extreme hyperæsthesia of an hysterical character, as before said, with dread, but no joint disease adequate alone to produce loss of motion. Twice this lady was etherized, and the legs extended by main force, pressure being applied directly over the joints sufficient to crush them down. Of course, the knees were made the fulcrum of the force applied to overcome the flexor muscles which were shortened and rigid from position. After the limbs were thus straightened out, apparatus was applied to keep them straight. But the articulating surfaces of the joints had been so bruised by the operation that she was in agony until the retaining apparatus was taken off and the knees relieved by bending. After repeating the process on two different occasions, without advantage, the case came into my hands. On listening to a history of the case, it immediately occurred to me that the failure was due to not providing against the necessity of using the knee-joint as the *point d'appui*. To avoid such articular pressure, I used a strong counter-extension hip-splint, and found no serious difficulty in straightening the limbs, and in keeping them straight without pain to the patient. Though extension at the knee-joint was made by the counter-extension hip-splint, it was by no

quite a number of eminent gentlemen had attempted to straighten without permanent success. The evident necessity for an instrument for *force trisic* operations on the knee-joint has resulted in the perfected machine which I have called "the eccentric genuclast," and will presently describe. Nothing could demonstrate the absolute necessity for such an instrument better than the case above alluded to. It was that of a lady, about forty-five years old, of a gouty diathesis, and an uncommonly sensitive and hysterical temperament. A slight arthritis in the knees served to excite uncontrollable terror of any movement, which she feared might cause pain, with the effect of keeping her in the sitting position for three or four years, and until the muscles had become stiff and the knee-joints immovable. I can positively assert that there was neither inflammation, swelling, adhesions, nor local tenderness in or about the knees when I saw her, and that the only restriction to the motions was the rigid and inelastic

means a perfect machine for the purpose. But it protected the joint from injury while the leg was extended on the thigh, the operation was relatively painless, and thus its use conclusively demonstrated an important principle. I mention this case merely to illustrate this one point. It then occurred to me that, if an hyperæsthetic joint could be extended with impunity in a case where the old methods had been carefully tried and had conspicuously failed, what must be the advantage in joints which had been seriously diseased? In straightening the limbs, in this case, I found that there should be a combined movement under regulation and control of both extension and counter-extension. Carrying out this principle, in other cases which I have practised on since, the result has been the eccentric genuclast, which I will now describe.

The genuclast may be seen applied in the figure. It consists of two pairs of clear, strong, ash bars, one inch and three-quarters square, *A A A A*, each pair

fastened together at right angles by strong mortised joints, which are further strengthened by the steel plates *BB*, which are securely bolted across from one arm to the other. On the lower or horizontal arms are the adjustable flanges *CC*, in the edges of which are holes for lacing the leather bands *DD*, which pass under the limb. To the flanges are also fastened the fixed leather stays, *EE*, which pass over the limb, and on which the instrument rests. *FF* are bands made of flannel, covered with chamois, which pass under the knee, as shown. The two parts are connected by and vibrate on the bolt *G*, which passes through projecting ears of the plates *BB* at a point three inches beyond the edge of the uprights, and as far above the lower angles *B'B'* of the plate. By this arrangement the angles are alternately approximated or carried apart with every vibration on the pivot *G*. From each end of the same bolt T-shaped flanges, *SS*, are projected downwards about two inches below the lower edge of the horizontal arms, and carry a piece of packing rubber which is curved from one to the other over the knee. While the elasticity of the rubber allows the patella to bury itself in it, it yields no more and will bear all necessary force without stretching. This arrangement is intended to prevent bruising the knee. The flange, *S*, is kept in position by the two braces, as shown. At the top of the vertical bars are two pairs of steel rods, *HH* and *JJ*; one pair, *HH*, having concentric racks, and the other, *SS*, having eccentric racks on their inner edges. These rack-bars are fastened to one upright by a common bolt at *K*, and pass through the upper end of an operating lever, *L*, above and below the pivot, *M*, on which it works when in use. *N* and *O* are pawls which throw the racks out of gear when elevated (as at *N*), and allow the rubber spring; *P*, to act and cause the racks to mesh on pins in the lever when depressed (as at *O*). With *N* vertical and *O* depressed, the eccentric racks are engaged, and, by moving the operating lever *L*, the uprights are forced apart and the knee bent; while, with *N* depressed and *O* vertical, the concentric racks are engaged, the uprights are drawn together and the knee straightened. But, in straightening, the angles *B'B'* are separated and the horizontal arms are made longer—carrying the upper and lower portions of the limb along with them and tending to separate the joint. There would be a strong extension at the knee with no other than the friction of contact. But, in cases of ankylosis, or where considerable force must be used, adhesive straps are applied to both thigh and leg, which are attached to the buckles *QR*, at the extremities of the flanges *C* and *C'*, so that in operating the lever *L* with the pawl *O* vertical and *N* depressed, there is extension of the leg on the thigh; and, at the same time and through the same moving force, counter-extension also at the knee-joint. Thus the knee-joint is effectually protected from hurtful pressure, either downward by the weight or action of the machine, or, concentrically, within the joint. It should be suspended and controlled by a cord and pulley, as seen. Whatever force is required to overcome the muscles or to break up or rupture osseous or fibrous adhesions, is received on the apparatus instead of impinging on the articulation. The movement may be instantly changed by altering the positions of the pawls *O* and *N*, from flexion to extension or the reverse.

And in cases where extraordinary force is necessary, or where no anesthetic is used, the flexion or extension, as the case may be, may be let back from each extreme point, very slowly and carefully, by using the lifter *T'U*, by which the racks may be lifted over,

tooth by tooth, and the tension gradually diminished, without shock or pain to the patient. In cases which resist less, the action of the instrument may be directly reversed, and thus motion in a stiffened knee-joint may be kept up without pressure or friction against the articulating surfaces.

The following two cases will show the practical utility of the eccentric genuclast in cases not amenable to the application of force, by any other means that I am aware of.

The first is a case of articular rheumatism, of eight years' standing, in a lady forty-eight years old. All, or nearly all the joints were more or less affected, but the greatest difficulty was experienced from the flexion and stiffening of the knee-joints, as the acute stage passed away and the chronic stage of the disease supervened. She was unable to walk, but managed to hobble by turning the knees outward and using crutches. There was a little motion and not much tenderness, considering the disease. She was subjected to three operations on each knee, under ether, with the effect of increasing her height two inches, and diminishing the flexion and increasing the motion at the knees so much that she could get about very comfortably. But the interest of the operation consists in the fact that she felt no effect whatever upon the joints as a consequence. She was a large, powerful woman, with thick, strong muscles, and the amount of force employed was, to me, astonishing. But she was invariably up and about the next morning—the operations always occurred in the afternoon—or as soon as she had recovered from the effects of the ether, and not only denied having any tenderness in or about the knee-joints, but would proceed with the passive movements, which were a part of her treatment, just as if nothing had happened, only there would be an increase of motion. The time required to increase this lady's height two inches was ten weeks. She was heard from six months after she went home, and, up to that time, retained all the improvement which she had when she left.

The other case was one of traumatic inflammation of the right knee-joint in a lady thirty-five years old. Four years before she fell on the ice, hitting the knee, and, within a few hours, was taken with acute inflammation of that joint. The history of the case shows that she was confined for some six months with acute inflammation of the joint. After a while abscesses formed, one after another, some of them discharging bone as well as pus, and the knee bore evidence, in its cicatricial markings, of the injury it had sustained.

The limb was flexed at a right angle, and perfectly rigid; the lady was very stout; there was still a small opening near the outer hamstring discharging a small amount daily, and there were brown, indurated patches about the upper and inner aspect; and, altogether, it did not seem to be a very promising knee to operate on. But I conceived the idea that the great flexion, in connection with the large amount of adipose in the popliteal space, might be unfavorable to the circulation and nutrition of the parts. Also to still further test the application of the genuclast, in a case of progressing inflammation, I resolved to try it. So on the 2d of May, 1878, in presence of Drs. Lewis Fisher and D. B. St. John Roosa, the instrument was applied, and the leg extended on the thigh until the flexion was reduced about one-half. The limb was then placed in a retaining apparatus which kept up a certain amount of counter-extension. During the operation, after the lever "L" had been moved a number of times, and the tension had become very great, a dull thud was heard, and the leg was immediately

extended, all that it was thought advisable to do at that time. The skin under the knee had begun to crack, and I feared that some of the vessels might be ruptured if the extension were carried any further until after the parts had had time to accommodate themselves to the new position.

Considerable discomfort was experienced during forty-eight hours after the operation, but it all proceeded from the stretched muscles and torn skin, and not at all from the joint. There was no increase of redness over the indurated patches on the inner aspect of the knee, nor any other symptoms to indicate that the articulation had suffered in the slightest degree from the force which had been applied. On the 11th of May, or just one week after the first operation, it was repeated.

This time the extension was carried to a point which was considered the most favorable for ankylosis to take place, and the limb was put up in the same retaining apparatus, but it had been straightened to suit the more extended position of the leg.

Everything seeming to be favorable, she left for home about two weeks after the second operation and resumed her business of teaching. On the first of October she returned for examination and further advice. I found less color and induration in the soft parts before mentioned, the sinus had closed several times, and, though opening again, there was less discharge; there was no tenderness about the joint, and there was some motion.

This case will be watched with much interest. But, be the ultimate result what it may, the immediate effects so far seem to point to the conclusion that the rigidity of knee-joints after articular rheumatism may be greatly ameliorated; and, more important still, that incipient ankylosis may be broken up, and retracted muscles overcome by repeated operations, without injury to a chronically inflamed knee-joint, when the eccentric genuclast is used for the operation. If this should prove in other cases to be the usual result, it seems to me that the conception which has given birth to this apparatus opens up some questions of very great interest to the profession.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND ITEMS OF TREATMENT.

INFLAMMATORY SORE THROAT—SIMPLE TONSILLITIS.

A MALE patient, *æt.* 20 years, was seen who had been sick two days. He was taken with a chill, which was followed by a fever and a feeling of soreness in his throat. His brother looked into his throat, and informed him that he had diphtheria. He then went to a physician, who also told him that he was suffering from diphtheria. He made application for admission to a hospital for children, was told that adults suffering from diphtheria were not received, and he then obtained admission to this hospital. He was admitted on the evening of the day he was taken sick. At that time his temperature was 103° F. On the following morning the temperature was 101½° F., and in the evening 102° F. On the next morning his temperature was 100° F.

The appearance of his throat had changed so much that there was nothing special to be seen, except swelling and redness of the tonsils, the mucous membrane

of the pharynx, and the uvula. The white patches which were upon the tonsils had entirely disappeared.

The patient had suffered, not from diphtheria, but from simple tonsillitis, or that form in which there was deposited a considerable amount of white matter upon the tonsils. It was remarked that such cases were very frequently mistaken for diphtheria. It was, however, regarded as a case of ordinary sore throat, which had been characterized by symptoms rather more severe than those usually present.

In this connection, reference was made to two cases of sore throat in which the symptoms deviated from those ordinarily present sufficiently to make them worthy of special mention.

CEDEMA AND CONGESTION OF THE UVULA—URGENT DYSPNEA—OPERATIVE INTERFERENCE.

The *first* was in a gentleman about 45 years of age, strong and vigorous. On examining his throat it was found that both tonsils were swollen, and regularly and symmetrically dotted with small white spots, indicating that each of the orifices of the crypts of the tonsils contained a white plug of mucus and epithelium. The patient had no febrile movement. On the following day, however, he was worse, the tonsils were more swollen than on the previous day, and the inflammation had extended to the pharynx.

The inflammation increased in severity from day to day; the tonsils became more and more swollen, and the swelling of the uvula and the mucous membrane of the pharynx became more and more marked. The uvula became enormously swollen. As the severity of the symptoms gradually increased, he as gradually lost his voice. On the fourth day he began to have considerable dyspnea, especially when lying. At the end of the fourth day the dyspnea became quite alarming. During the entire night he was scarcely able to get his breath, and spent most of the time in coughing and gagging efforts to obtain inspirations. On the next morning the dyspnea was still more marked. During one attack he became almost cyanotic, and it was thought he was dying. When examined, it was found that the tonsils and uvula touched each other, and were so much swollen that it was impossible to see the pharyngeal wall. It seemed evident that the dyspnea, to a very great extent, was caused by the swollen uvula. The uvula was as large as an ordinary thumb, and it seemed to act as a barrier to the entrance of air into the larynx. The indications were pressing, and the uvula was at once slit with an ordinary sharp-pointed bistoury thrust into it, and cutting directly downward. This gave the man relief very promptly, and during the course of the day the relief was still more apparent.

On the following day it was evident that suppuration was taking place in one of the tonsils which had been extensively swollen, and soon after rupture of the walls of the abscess occurred, and pus was discharged from the mouth. Very marked relief followed the evacuation of the pus, and the patient was soon convalescent. The entire duration of the inflammation was about two weeks, and at one time there was really considerable danger of suffocation.

PHLEGMONOUS INFLAMMATION OF THE UVULA—URGENT DYSPNEA—INCISION—RECOVERY.

In the *second* case the condition was more unusual than that seen in the case just related.

The patient was a young woman. On examining the throat it was found that the tonsils were slightly swollen, and that there was considerable pharyngitis. She had been subject to ordinary attacks of sore

throat, and had also had several attacks of suppurative tonsillitis.

A palliative remedy was ordered. The patient came under observation five days afterwards, when it was found that during the entire time she had been gradually getting worse. There was, however, no febrile movement, but she had not been able to take any food for two days, because of the pain which was produced by any attempt to swallow. She had not been able to lie down, because as soon as she made the attempt she felt as though she were choking. When her throat was examined it was found that apparently the tonsils were no more swollen than at first, and they were perfectly clean. There was a moderate amount of general pharyngitis, but the surface of the mucous membrane was entirely clean. The uvula, however, was very much swollen, and the swelling was particularly in its antero-posterior diameter. It was not only swollen, but it was extremely congested; it was of a purple color. In addition to the swelling and congestion, the uvula was completely covered with a material which presented very much the appearance of false membrane—a pretty thick layer of whitish material. The appearance suggested the presence of diphtheria.

The conclusion was however reached that it was a case of inflammation of the uvula, the inflammation involving not only the mucous membrane, but all the tissues of the uvula. In other words, it was regarded as a case of phlegmonous inflammation of the uvula, and the coating which was present was really nothing more than mucus produced by an excessive action of the mucous glands and follicles.

The dyspnoea was not particularly alarming, although she could speak only in a whisper.

On the following morning the dyspnoea was considerable, and she had attacks which were very severe. She was then able to speak only in a very low whisper, and some doubt was felt as to whether a mistake in diagnosis had not been made, and that it was really a case of diphtheria, which had extended into the larynx.

The throat, however, presented the same appearance it did the day before, the evidence of inflammation being confined entirely to the uvula. But the dyspnoea was rather that of œdema glottidis than that produced by any change in the larynx. It was chiefly upon inspiration, and was not attended by any laryngeal voice or laryngeal cough. She was able to fill her lungs without difficulty when she was sitting up and was quiet. The dyspnoea, however, was so alarming that the necessary steps were taken to have some one ready to perform tracheotomy at any time in the course of the day, if it became necessary. In the meantime the plan of treatment adopted in the first case was carried into effect, and the uvula was incised with a sharp-pointed, curved bistoury, as in the preceding one; incision of the uvula was followed by almost immediate relief. The woman continued to improve, within twelve hours the dyspnoea had entirely disappeared. In addition to slitting the uvula, a gargle containing tannin and iodoform was ordered. The coating of mucus which was upon the uvula quickly disappeared, and it was then evident that there had been phlegmonous inflammation of the uvula. For it could be seen that the tip of the uvula had fairly sloughed, and there was left behind a surface which had commenced to granulate.

ABSCESS OF THE KIDNEY BY ASPIRATION.—Arthur Lucas, M.R.C.S., reports (*Lancet*, Sept. 28th) the successful treatment of a case of abscess of the kidney by aspiration.

Progress of Medical Science.

CEREBELLAR LESION WITH HEMIPLEGIA AND APHASIA.—Dr. Ringrose Atkins reports a very interesting case, which is extremely important in its physiological bearings.

The patient, æt. 38 years, was admitted into Waterford Asylum, May 8th, '77; she had been of an excitable and eccentric disposition from childhood, and occasionally had mild epileptic fits since youth. Some time ago she had a severe epileptic seizure followed by right hemiplegia and aphasia, which lasted three weeks, but she completely recovered. A little time before admission she had occasional paroxysms of violence, and developed various delusions. On the morning of June 8th she was found to have become affected, during the night, with right hemiplegia and complete aphasia; sensation was also completely abolished on the paralyzed side. On June 13th the patient suddenly became affected with unilateral right-sided convulsions; she died on June 16th.

Autopsy.—The vessels of the arachnoid and pia mater were distended with dark-colored fluid blood. The vessels at the base of the brain were atheromatous. No embolus or other plugging of the vessels could be detected even in the minute divisions of the middle cerebrals. Both opto-striate bodies were flabby and flattened, the posterior extremity of the left optic thalamus more markedly so. The left lateral lobe of the cerebellum was so softened and broken down that a considerable gap was produced in its external border.

Ferrier states that it is established beyond all question that lesions of the cerebellum do not cause hemiplegia of the opposite side of the body, except when it produces compression of the subjacent track of the pons and medulla. There is also overwhelming evidence in support of the assertion that cerebellar lesions do not cause loss of tactile sensation. With this seeming contradiction, the hypothesis of Brown-Séquard cannot be overlooked, that the lesion of the cerebellum may have produced the paralysis by an irritation which restrained and arrested the action of nerve cells, at a distance from the seat of the lesion (inhibition). The question arises whether the hemianæsthesia was connected with the partial wasting of the left optic thalamus, but this cannot be answered satisfactorily. Keeping in mind the morbid conditions occurring elsewhere, this state of the optic thalamus, with the probable degeneration which existed both in its histological elements and in those of the corpus striatum, gives some show of support to the hypothesis that the functional activity of these ganglia, already weakened, was finally arrested by the irritative lesion in the cerebellum, the route by which the motor impulses travel downwards from the speech centre, being at the same time interrupted and resulting in aphasia.—*Brain*, Oct., 1878.

CONGENITAL ABSENCE OF HAND, AND CORRESPONDING ATROPHY OF THE BRAIN.—Dr. W. R. Gowers, in "*Brain*" of Oct., 1878, gives the results of an autopsy in a case of congenital absence of one hand. Dissection of the arm showed that the bones of the forearm were normally developed, but that at their extremity there was only an irregular mass of bone, apparently corresponding to the carpus.

The two hemispheres of the brain were nearly of the same size. The frontal and ascending frontal convolutions were nearly of the same area, but a marked

difference existed between the two ascending parietal convolutions. At their origin in the longitudinal fissure they were quite equal in size, and continued so for the upper inch and a half. In the next (middle) two inches there was a very marked difference, the right being a narrow single convolution, and the left broad and depressed by a slight secondary sulcus. The lowest extremities of the two convolutions were equal in size. Otherwise, the two sides of the brain were alike.

The chief interest of the case arises from the fact that the diminution of size in the ascending parietal convolution on the opposite side of the brain occupies precisely the area, stimulation of which, according to Ferrier's experiments upon monkeys, causes movements of the opposite hand. In several instances, in cases of old amputation of the arm, an atrophy has been found, but it has been slight and has not been uniformly localized. The strict limitation of the atrophy to the hand region, in this case, affords striking support to the experimental results.

INSANITY CURED BY TREATMENT OF A UTERINE DISPLACEMENT.—In a communication to "Brain" of July, 1878, on the cure of a case of insanity by the correction of a coexisting uterine displacement, Dr. Savage gives the following history: E. G., married, *æt.* 45 years; no hereditary tendency to insanity; has just passed the change of life. Symptoms of insanity began two months ago; the patient began neglecting her home duties, attempted suicide, and had delusions of "persecution." Morphia was tried, but it produced sickness and did no good; patient remained in same mental condition for two months. Dr. Savage then discovered that she had a large, heavy uterus, which was much prolapsed, and accordingly kept her in bed for some days. She was more quiet at first, but, finding that the uterus would not keep its place while the patient was lying down, Dr. Savage introduced an air-pessary, and thus maintained the womb in position. Within twenty-four hours the patient was feeling better, and evidently improving in intellect. Within a week she was comfortable, but the temporary removal of the pessary again caused mental distress.

In three weeks from the introduction of the pessary she returned to her family, and has remained quite well ever since (a period of four months).

SYPHILITIC EPILEPSY.—From records of 274 cases of epileptiform seizures of an undoubted syphilitic origin, Dr. Thomas Stretch Dowse summarizes his observations very briefly as follows: The age of the patient is an important guide. Should a man or woman be attacked by epilepsy between thirty and forty years of age, without having any hereditary predisposition, or a previous seizure, then a syphilitic cause may be apprehended. And, apart from this, provided that between the attacks there is more or less mental derangement, our basis for a diagnosis is greatly simplified, and it is even more so if there be a paresis more or less profound, localized, or unilateral, but gradually passing off after the epileptiform seizure. The reflex processes are rarely if ever completely absent. The iris may contract under the influence of a strong light; the lips close when the conjunctiva is tickled, and a state of anti-consciousness, rather than profound coma, is a prominent feature from first to last.

The stages of the attack are ill-defined, and merge the one into the other. The universal tonic spasm, with thotonism, rarely presents itself. Pallor, rather than cyanosis, is the facial exponent, and the dura-

of the fit is protracted to many hours, with intervals of wandering, delirium, and excitement. Foaming at the mouth is less prominent than a profuse flow of saliva, and all sorts of cries are associated with the seizure; but they are rarely so exalted as Romberg expresses it, "Shrill and terrifying to man and beast."

And, lastly, in reference to albumen in the urine. Considerable attention has been given to this point, but it has not been found in any but a few of the cases; but epileptoid seizures, associated with albuminoid syphilis, and a plentiful secretion of phosphatic albuminous urine, are not uncommon.—*The Practitioner*, October, 1878.

THE TRANSFUSION OF BLOOD IN A CASE OF OPIUM-POISONING.—Dr. Thomas G. Morton, of Philadelphia, recently performed transfusion at the Pennsylvania Hospital, in that city, in a serious case of opium-poisoning. The patient, a man of some forty years of age, was brought into the hospital in a comatose condition. In order to relieve the system of the poison a large quantity of blood was drawn from him before transfusing the patient. Eight ounces of defibrinated blood were then thrown into the saphena vein on the right foot. The pulse rose, the respirations increased in number after the operation, and the patient began to grow steadily better, when, five hours after the fresh blood had been introduced, his heart suddenly ceased beating, and he died without a word.

RECENT ACUTE MYELITIS IN AN INFANT; SOFTENING OF ANTERIOR CORNUA.—The patient, *æt.* 2½ years, was admitted into hospital December, 1877. Four weeks previously it had had a fall. Ten days afterward it grew ill, and two or three days later mother noticed paralysis of left arm and leg. Upon admission, there was complete paralysis of motion and sensation in the legs, and of motion in the arms; complete loss of reflex action in the limbs. The evacuations were involuntary. Temperature ranged from 99°–100° F. Two weeks later the child was less dull, and power was beginning to return to the arms. A few days later arm-movements were quite free; the legs were sensitive, and could be drawn up in bed. The child now began to suffer from measles, and died Jan. 24, 1878, of secondary broncho-pneumonia.

Autopsy: The gray matter of the cord everywhere thickened, with spots of red softening in the anterior horns of lumbar region. Numerous leucocytes were seen in the perivascular spaces in the lumbar region, just above the softened parts. The ganglion-cells were gone on the left side, and their places taken by leucocytes, granular bodies, and free nuclei. There were scarcely any polar cells in the posterior horns; numerous nuclei along the vessels, and scattered in groups throughout the horns. The changes in the cervical were very marked, more so than in the dorsal. The only change in the medulla and pons consisted in an increase of leucocytes. Distinct sclerosis was visible in the antero-lateral columns. The accumulation of leucocytes around vessels was seen in otherwise healthy parts. This appears to suggest that the disease at first affects the vessels only, the nerve-structures being secondarily involved.—*Dr. Turner, London Path. Soc., Feb. 4, 1879.*

CLIMATE OF AFRICA.—South Africa is recommended by Harry Leach, M.R.C.S. (see *The Practitioner*, Oct.), as a fine climate for certain consumptives and other invalids. Dry air and pretty even temperatures are the peculiarities of the climate.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 15, 1879.

THE NATIONAL HEALTH BUREAU.

A BILL calculated to prevent the introduction of infectious or contagious diseases into the United States, and to establish a National Board of Health, passed the House of Representatives during the last day of the session of that body. To such as have watched the progress of legislation regarding the creation of a health bureau, and have taken an impartial view of the necessity for such a department, there will be much disappointment at the result.

The bill in question was presented by Mr. McGowan, of Missouri, and after very little debate was duly passed. It provides for the establishment of a National Board of Health, to consist of seven members, to be appointed by the President, by and with the advice and consent of the Senate, not more than one of whom shall be appointed from any one State. The compensation of the members during the time when actually engaged in the performance of their duties under this act, will be ten dollars per diem each and reasonable expenses, and of one medical officer of the army, one medical officer of the navy, one medical officer of the marine hospital service, and one officer from the Department of Justice, to be detailed by the Secretaries of the several departments and the Attorney General, respectively, and the officers so detailed will receive no compensation. Said board will meet in Washington within thirty days after the passage of this act, and in Washington or elsewhere, from time to time, upon notice from the president of the board, who is to be chosen by the members thereof, or upon its own adjournments, who will frame all rules and regulations authorized or required by this act, and make or cause to be made such special examinations and investigations at any place or places within the United States or at foreign ports, as they may deem best, to aid in the execution of this act and the promotion of its objects.

The duties of the National Board of Health are

simply to obtain information upon all matters affecting the public health, to advise the several departments of the government, the executives of the several States, and the Commissioners of the District of Columbia, on all questions submitted by them, or whenever, in the opinion of the board, such advice may tend to the preservation and improvement of the public health.

Section third of the bill provides, "that the board, with the assistance of the Academy of Science, shall report to Congress at its next session a full statement of its transactions, together with a plan for a national public health organization, which plan shall be prepared after consultation with the principal sanitary organizations and the sanitarians of the several States of the United States, special attention being given to the subject of quarantine, both maritime and inland, and especially as to regulations which should be established between State or local systems of quarantine and a national quarantine system.

"Sec. 4. The sum of fifty thousand dollars, or so much thereof as may be necessary, is hereby appropriated to pay the salaries and expenses of said board."

After so much time spent in legislation upon sanitary matters, and so much discussion upon the different health bills which have been presented to Congress, it is a matter of great regret that more has not been accomplished. The board, although admirably constituted and calculated for much effective work, has really nothing more than advisory power, and is calculated to act merely in the capacity of a committee of inquiry regarding a plan for a future national health organization. So far as the establishment of any system of national quarantine is concerned, nothing has been accomplished. The wisdom of such an omission is certainly very questionable, especially in view of the probability of the reappearance of yellow fever next summer.

All the investigations which have been held recently concerning the spread of yellow fever have demonstrated the necessity for quarantine. The only difference of opinion appears to be concerning the rigidity of the restrictions. The majority of advanced sanitarians are on the side of common sense, and believe that efficient quarantine is consistent with protection of the people on one hand, and that of commerce on the other. It does not appear that any further investigation on this point is necessary, at least in view of prospective emergencies. The history of the last epidemic also demonstrated that something more than local or State quarantine was necessary. While railroad stations were guarded with shot-gun patrolmen, while towns were surrounded by armed citizens, while refugees were banished to the swamps, and charity was lost in fear, the rivers were open to free traffic, and the decaying corpses of the victims of fever were transported for miles without hindrance. It was not until the disease had gained a secure foot-

hold along the Mississippi that the inhabitants on its banks took matters in their own hands for self-protection. It cannot be doubted that if some intelligent and uniform system of quarantine was enforced by a power stronger than that of the local authorities, that much needless suffering would be prevented and many valuable lives saved. The question is whether these experiences of the past year are to be repeated during the next summer; and if so, what is going to be done to stay the progress of the pestilence while the new health board is deliberating upon their next report to Congress.

The other bills, any one of which was better calculated to protect the people than the one in question, were defeated in consequence of the ultra views on State's rights entertained by many of the Southern and New York members. It has not yet been proven, however, that such rights would have been interfered with by any provisions contained in the bills aforesaid. On the contrary, it was designed in each instance that the federal government should merely aid the States in times of emergency, and not in any way interfere with their respective rights. So strong, however, was the feeling regarding this doctrine of State's rights that a clause in the original bill of Mr. McGowan, to the effect that the health board should aid in the work of State boards of health, and in that of State or municipal quarantine authorities, was stricken out, thus completely depriving the Act of its greatest, if not only means of real usefulness.

AURAL HYGIENE AND THE PUBLIC SCHOOLS.

THE eighth annual report of the New York Ear Dispensary has just been issued, and the workings of the institution are set forth in the report of the trustees. Since the establishment of this charity it has been the aim of the trustees to improve the condition of the partly deaf children found in the public schools, the officers of the dispensary having had forced on their attention from year to year the neglect shown this class.

It would appear to be a natural and simple matter for teachers to seat children with this defect sufficiently near their desks to make themselves heard; yet it is well known that, for the guidance of teachers in this matter, there are no established rules in the schools. Bitter complaints are frequently made at the dispensary, by parents, of the neglect of partly deaf scholars at examinations for promotion; those not hearing well enough to promptly catch questions fail to give correct answers, and are thus unable to secure a promotion to which they are clearly entitled.

This failure to comprehend the status of a class whose number is really greater than generally supposed, imposes increased labor on the already much-taxed teacher, and the partly deaf are thus compelled to learn under great disadvantages, as well as being a hindrance to others. The trustees recommend, as a

means of solving this difficulty, in part at least, that the hearing power of each pupil be tested before he is assigned to a seat, and they suggest a very simple plan intended to aid teachers in carrying out this matter, instructions for which are printed in the end of the report. The trustees dwell with much earnestness on the imperfect hygiene of our public schools, and, indeed, if we are to credit one-half the complaints coming from many and various sources on this subject, the present system could go back and borrow considerable knowledge from the old log school-house of early days. A defective system of heating and ventilation seems to be at the bottom of this evil, and its direful influence on the youth who pass many hours daily, at an important period of their physical development, in a foul atmosphere, cannot be over-estimated, and it seems especially hard when it is considered that attendance is in part compulsory. The city has here an opportunity to establish model houses for school purposes, and they should certainly do this before enacting laws to enforce the construction of model tenement-houses by others.

The report further says: "Attacks of inflammation of the ear frequently occur from seating children too near a stove, or other source of heat, or permitting them to be exposed to a draught of cold air near a window or door. The former are rendered very sensitive to colds thereby, and an earache, with purulent discharge from the ear, frequently follows. This source of aural disease could be greatly lessened by a better system of heating and ventilation."

Believing that an early attention to throat affections is likely to lessen the frequency of aural diseases, the trustees have considered it best to re-establish the Throat Department, and, being convinced that aural surgery can be made serviceable in the same manner, they have also established a Dental Department.

The report of Samuel Sexton, M.D., the Aural Surgeon-in-Charge, states that during the year 575 patients were treated. He draws attention to the change in the nomenclature of aural diseases which has been made necessary by the requirements of modern aural pathology. Thus, "impacted" cerumen is not enumerated as a disease; in fact, the presence of cerumen in the external auditory meatus is owing to an anomaly of secretion, and its "impaction" is not an invariable incident. Affections of the tympanum are classified as nearly as possible according to their pathological significance, and *symptoms* of disease, as tinnitus aurium and the like, are not included in the list as diseases.

THE INDEX OF THE LIBRARY CATALOGUE.

THE authorization of the printing and binding of the first and second volumes of the index catalogue of the library of the Surgeon-General's Office will be a subject for congratulation with medical scholars through-

out this and other countries. A clause in the Sundry Civil Appropriation bill names twenty thousand dollars for that purpose. The volumes are promised by June, 1880. Although the succeeding volumes are not yet provided for, a proper initiation has been taken, and there will be no doubt, when the time for the publication of these arrives, the means for so doing will be forthcoming. The profession has taken a great interest in the project, and too much praise cannot be given to the legislature for its action in bringing about the result.

Reviews and Notices of Books.

THE CONSTITUENTS OF CLIMATE, with Special Reference to the Climate of Florida. By FREDERICK D. LENTE.

ANY well-directed effort to enlighten the profession on the subject of climate should be hailed with delight. Dr. Lente has laid the profession under obligations for his carefully written pamphlet. He has added much to our knowledge of the climate of Florida, and has made this knowledge practical by aiding the physician to answer the questions so often asked by the patient: "Where shall I go?" "When shall I go, and how soon will it be safe for me to leave the climate to which I go, and return home?" Dr. Lente is in a position to judge, having spent several winters in Florida, and having made the climate and its influences a special study.

At this season of the year, when both physician and patient are interested in the subject, the information is specially valuable.

Considerable space is given to the subject of the influence of climate on pulmonary diseases. Almost all physicians are agreed that phthisical patients receive the greatest benefit in that climate in which they may be most out of doors. Dr. Lente shows that Florida offers a climate which permits of the patient being out of doors even more than Europe's favorite winter homes, Mentone, Cannes, Nice, etc.

Dr. Lente also gives great encouragement to the sufferer from malaria, that the climate of Florida will benefit him. For sufferers from the early stages of Bright's disease, the so-called nervous prostrations, throat affections, certain forms of dyspepsia, and rheumatism, Florida offers a climate well adapted to benefit.

Dr. Lente points out one great error that patients from the North are apt to fall into, and that is in regard to diet and clothing. They forget in the change of climate to change the diet to suit that climate, and the result is an attack of indigestion, which aggravates their already existing diseases. Dr. Lente thinks thicker clothing should be worn in Florida than in New York for the same temperature. Any patient going to Florida or any other locality for the benefit of his health should seek the advice of some intelligent physician in the locality to which he goes, and not depend on the general advice of his physician at home.

TRANSACTIONS OF THE OHIO MEDICAL STATE SOCIETY. THIRTY-THIRD Annual Meeting, held May, 1878. Columbus, Ohio: Cott & Hann. 1878.

AFTER the report of the "minutes" of the Society, we are brought face to face with the papers presented at

this meeting. That of the retiring president, Dr. W. Philips, of Kenton, upon "The Testimony of Medical Experts," is one of much interest and value. The author holds that the State should provide a man whose special education and training renders him competent to instruct the judge and jury upon points which can only be mastered by special scientists. We heartily agree with Dr. Philips.

Prof. J. W. Hamilton, M.D., records four very interesting cases of "Maxillary and Naso-Pharyngeal Tumors," with remarks upon the operations. "Throat and Nasal Affections in their Relations to Diseases of the Ear" is an interesting and instructive paper by Dr. J. H. Buckner, of Cincinnati. Scarlatina, measles, variola, coryza, pertussis, enlargement of the tonsils, diphtheria, syphilitic sore throat, hereditary syphilis, adenoid vegetations (naso-pharyngeal), as well as more ordinary inflammatory affections of the naso-pharynx, are given as the causes of ear diseases.

Dr. C. S. Muscroft has great faith in "The Use of Sub-sulphate of Iron as a Local Remedy." "The Curette in Certain Forms of Uterine Diseases, with Cases," by Thad. A. Reamy, M.D., calls for no special mention.

Dr. R. L. Sweeney gives "A Report on Chronic Inversion of the Uterus." He employed White's repositior with success.

The remaining five papers, and an obituary report, are of no particular interest. A list of members is appended. The officers elected for the ensuing year were: *President*, B. B. Leonard, West Liberty; *Treasurer and Librarian*, T. W. Jones, Columbus; *Secretary*, J. F. Baldwin, Columbus.

PROCEEDINGS OF THE FLORIDA MEDICAL ASSOCIATION Session of 1878.

The officers elected for the present year are: *President*, R. D. Murray, Key West; *Secretary*, J. Y. Porter, Key West; *Treasurer*, J. D. Fernandez, Jacksonville. The transactions of this association narrowed themselves to the simple presentation of two very lengthy and valuable papers upon Yellow Fever as it occurred at Jacksonville and Fernandina. The former was read by R. P. Daniel, M.D., the latter by C. W. Horsey, M.D.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA, 1878.

THIS Society held its annual meeting in the town of Weston, May 22d and 23d, 1878. At this meeting it elected the following officers for the ensuing year: *President*, Wesley H. Sharp, Volcano; *Secretary*, M. P. Hullivan, Wheeling; *Treasurer*, J. C. Hupp, Wheeling.

This volume contains, besides the "minutes" and an address by the retiring president, Dr. J. W. McSherry, nine papers. Drs. M. R. Boyd and J. H. Brownfield each report an interesting case of "Extra-Uterine Pregnancy." Portions of the fetal skeleton were removed, in one case through the abdominal walls, in the other per rectum. "Puerperal Insanity," by A. H. Kunst, M.D., in nowise adds to our knowledge of the pathology or treatment of the affection. Dr. W. H. Sharp, "Concerning the Dressing of Wounds," gives a short but excellent review of Lister's dressings and their modifications.

Among quite a number of "Surgical Cases" reported by John Frissell, M.D., Wheeling, which are of no special interest, we find several very interesting ones of traumatic aneurisms and injuries of arteries. The other papers contained in this pamphlet are of insufficient interest to warrant mention.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA. Twenty-eighth Session, 1878. Phila.: Collins. 1878.

WE heartily welcome this last volume of the Society's Transactions, so full it is of excellent practical and instructive papers. At this annual meeting the president-elect, Prof. D. Hayes Agnew, presided. The officers for the ensuing year were elected as follows: *President*, J. L. Stewart, Erie County; *Permanent Secretary*, W. B. Atkinson, Philadelphia Co.; *Recording Secretary*, J. N. Kerlin, Delaware Co.; *Treasurer*, Benj. Lee, Philadelphia Co.

Prof. D. Hayes Agnew, M.D., delivered an address upon "Errors in Diagnosis," which is of great interest, and goes to show that not even the best of us are infallible, as the series of blunders which he relates as having been made by Dupuytren, Pirogoff, Diefenbach, and many others of eminence, prove. Prof. Wm. Goodell, M.D., delivered an address in Obstetrics, on "Lacerations of the Cervix Uteri." He refers in the outset to the fact that Emmet "has written pretty much all that can be said about it." Dr. Goodell, however, gives an excellent account of the etiology, pathology, sequelæ, and treatment of the affection under consideration, and records two cases.

"The Rational Treatment of Stricture of the Urethra," by Prof. S. W. Gross, M.D., further exemplifies the views reported in THE MEDICAL RECORD for June 15th and October 5th, 1878. The author accepts the treatment so ably advocated by Prof. Otis, namely, the restoration of the canal to its original calibre, as determined by the urethrometer, whether by urethrotomy or division. Dr. Gross gives the preference to internal urethrotomy.

Dr. J. B. Murdoch, of Pittsburgh, reports a rare and exceedingly interesting "Case of Dislocation of the Hip, complicated with Fracture of the Femur." Much space is given to points in diagnosis, and we can congratulate those who have the opportunity of reading this valuable paper. "Psoas Abscess simulating Nervous Affections," by Charles K. Mills, M.D., and "Clinical Study of Catarrhal Inflammation of the Bile-Ducts, with Remarks on the Use of Nitrate of Silver in its Treatment," by William Pepper, A.M., M.D., are two excellent papers. Want of space forbids further specification of the many remaining papers read before the State Society's meeting and at the meetings of the various county medical societies. Some of these papers are so valuable we regret being obliged to pass them by.

LECTURE ON BRIGHT'S DISEASE OF THE KIDNEYS, delivered at the School of Medicine of Paris, by J. M. CHARCOT, Professor in the Faculty of Medicine, Paris, Physician to the Salpêtrière, etc. Translated, with the permission of the author, by Henry B. Millard, M.D., A.M. New York: William Wood & Co. 1878.

THERE has long been felt the want of a brief work on the pathology of Bright's disease of the kidneys, one that should sift out all that is theoretical, and present to the busy practitioner and student all that is known of the affections of this organ coming under the general name of Bright's disease. These lectures of Charcot supply such a want. The work consists of seven lectures, two on the normal anatomy of the kidney and the physiology of urinary secretions; one on tubular infarctus, urinary casts, and a summary view of Bright's disease. Then follow two lectures on interstitial nephritis, one on parenchymatous nephritis, and one on the amyloid kidney.

He considers that all forms of disease of the kidney coming under the head of Bright's disease, not only from an anatomico-pathological point of view, but as

regards etiology and symptomatology, belong to one of three varieties, namely: interstitial or parenchymatous nephritis, or the amyloid kidney.

Under each head he gives an account of the etiology, symptoms, anatomical characteristics, and histology of the variety under consideration. He considers "that scarlatinous nephritis is confounded by many authors with parenchymatous nephritis, and that the point of departure of permanent lesions attributable to the large white kidney is founded on no decisive observation, but that histological examinations concur in showing the renal alteration to be a form of acute or subacute variety of interstitial nephritis." He does not touch on the question of treatment. The volume is illustrated with sixteen woodcuts and two chromo-lithographs. The thanks of the profession are due to the translator, Dr. Millard, for the way in which he has performed his portion of the work, and to the publishers for the clear type and elegant appearance of the book. It should be read by every one who desires to be informed of the pathology of Bright's disease.

A HAND-BOOK OF NURSING, FOR FAMILY AND GENERAL USES. Published under the direction of the Connecticut Training-School for Nurses, State Hospital, New Haven, Connecticut. Philadelphia: J. B. Lippincott & Co. 1879.

THE number of books on nursing that have been issued within the past few years show that the subject is at last receiving the attention it deserves. This book is one of the best that we have seen; it is really what it claims to be: "a hand-book of nursing," medical, surgical, and monthly. It is clear and practical in its instruction, and is intended not only for the professional nurse, but for every one who may be called upon to take care of the sick. It should find a place in every family. The chapter on "Family Hygiene" is particularly to be commended, short as it is. The volume is a credit to the committee under whose direction it has been prepared and published.

PRACTICAL GYNÆCOLOGY. A Hand-book for Students and Practitioners. With illustrations. By HEYWOOD SMITH, M.A., M.D., Oxon., etc. Demy 8vo. Philadelphia: Lindsay & Blakiston. 1878.

THIS is another volume of the "Student's Guide Series." While we admit it may be valuable for the "last year's" student to refresh his knowledge, any "busy practitioner" who feels the need of such a superficial work as this for consultation must necessarily have so limited a knowledge of gynæcology as to be unfit to attempt its practice. We are not a little surprised to be made aware of Dr. S.'s complacent estimation of his work by reading, in the preface: "If I have rendered the subject of Gynæcology more easily understood, and placed in the hands of general practitioners a means of helping them to a more accurate diagnosis [!] and treatment of diseases that form an increasingly important branch of their practice, my labor will be amply repaid."

ELEMENTARY AND QUANTITATIVE ANALYSIS. By ALEXANDER CLASSEN, Professor in the Royal Polytechnic School, Aix-la-Chapelle. Translated, with Notes and Additions, by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, University of Pennsylvania. Royal 12mo. 324 pages, with illustrations. Philadelphia: H. C. Lea. 1878.

THIS handsome little volume should receive a hearty welcome from American students of chemistry. The fact that it has been adopted as a text-book in Germany, and by many of the prominent universities and polytechnic schools in France, Russia, and Poland, where translations have appeared, should be a suffi-

cient guarantee of its worth. The student will find herein detailed the necessary practical methods—those only which have stood the test of experience, for *quantitative* analysis of minerals and their compounds. It deals with *inorganic* substances only. We can fully recommend it as an eminently useful and practical book, indispensable in the laboratory.

MODERN MEDICAL THERAPEUTICS: A Compendium of Recent Formulae and Specific Therapeutical Directions, etc. By GEO. H. NAPHEYS, A.M., M.D. Sixth edition, enlarged and revised. Philadelphia: D. G. Brinton, 115 S. Seventh St. 1879.

We are hardly surprised to find that the sixth edition of this work is before us within a period of time which is so short. The editor has given the work a thorough revision, expanded it to the necessity of an extra volume on diseases of women (to appear shortly), and has added in the present volume the subjects of Typhus Fever, Yellow Fever, Mercurialism, Plumbism, and a number of Diseases of Children. This work evidently supplies "a want long felt."

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 12, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

VESICAL CALCULUS.

DR. WYETH presented a stone originally two inches in diameter, which he had removed from a gentleman about fifty years of age. Lithotripsy was considered inexpedient on account of the large size of the stone and its peculiar position (being lodged in a sac or pouch behind the pubis). The median operation was first made and the stone was crushed with the forceps. In order to remove the fragments, some of which were very large, the primary incision was enlarged laterally.

The patient died from shock and exhaustion due to vomiting, about ten days after the operation. The pieces which were saved weighed 640 grains.

COMPOUND FRACTURE OF THE FEMUR—GANGRENE—HOT-WATER TREATMENT.

DR. FOREST presented a portion of a lower extremity, accompanied by the following history: A boy, four years of age, on December 3, 1878, fell from a third story window, an unbroken fall of thirty feet, and received a compound fracture of the femur. A surgeon was called who applied a plaster-of-Paris dressing. Soon after the child became uneasy, complained of great pain, and the toes became cold, but the surgeon regarded the symptoms as unimportant, and allowed the dressing to remain.

The patient was not able to either eat or sleep, and finally, after the lapse of several days, the splint was removed, when the foot was found gangrenous. The gangrene extended, high fever developed, the child passed into a low cachectic condition, and apparently there was no chance of his recovery. Several surgeons were called, but no encouragement was given with reference to saving the life of the patient. One of the surgeons recommended, as the only hope, that the

limb be amputated at the point of fracture. Dr. Forest was called December 15th, and then found that gangrene had extended up the leg, and the appearance of the limb was such as indicated its spread above the knee. He determined to make an effort to save the life of the patient by means of the hot water treatment, and therefore had a tin trough made in which the limb could be placed. It was then flowed with water at 112° F., and covered with cotton about three inches in thickness. The temperature of the water was steadily maintained at 112° F. From that time the gangrene ceased to extend. The pain passed away quickly, the child began to sleep, his appetite returned, and there was a rapid and marked improvement in his general condition. On the second day after the hot water was first applied, a line of demarcation began to form at the junction of the middle, with the upper third of the leg. About three weeks later the separation was complete, except at the posterior part of the leg, where a narrow strip of tissue still retained its vitality. In the meantime the wound in the thigh had healed, and the fracture had united. The general condition of the patient being good, Dr. Forest made an amputation, gave the lad a good stump, and preserved the integrity of the knee-joint.

CONTAGIOUS PLEURO-PNEUMONIA IN CATTLE.

DR. LIANTARD presented a lung removed from an animal that had died of contagious pleuro-pneumonia. At the request of the Board of Health, he had examined several cattle, had recognized the presence of the disease, and the lung presented was one obtained at a post-mortem upon one of the animals examined. The specimen exhibited the gross appearance of acute lobar pneumonia in which the development of interstitial tissue was a prominent feature. In places the lung was evidently in the stage of gray hepatization, and at several points suppuration had been established. A portion of the pleura removed from the region of the ninth rib was also presented, and showed firm thickening to the extent of nearly half an inch. Dr. Liantard regarded the disease as one produced by blood poisoning. After it had been of some standing, the lungs became of enormous size, weighing as much as forty or fifty pounds. The general period of incubation was about two months, and the infectious character of the disease varied, not only in different localities, but in different degrees in the same locality. That is to say, sometimes cows in the same stable with animals affected would escape, even the animal next to the sick one would be free from the disease, while one, two, or three removed would be attacked. There were no laws known which governed the matter of contagion. It was considered obligatory upon the part of owners of cattle to destroy the animals affected, inasmuch as there was no cure for the disease, and the animals were rendered unfit for food. He stated that in a large herd of cattle upon Long Island, there was scarcely a single animal uninfected. Inoculation had been tried, and without satisfactory results, in the way of preventing the disease.

DR. W. M. CARPENTER referred to a post-mortem which he made upon a calf that died of sporadic pleuro-pneumonia, and apparently without symptoms. The animal took his evening meal as usual, and was found dead in the yard on the following morning. None of the other animals were affected. There was a moderate amount of pneumonia and very extensive pleurisy, the exudation being soft and nearly half an inch in thickness.

CASE OF CHRONIC PACHYMEINGITIS HEMORRHAGICA INTERNA—EARLY STAGE—SMALL KIDNEYS AND HYPERTROPHIED LEFT VENTRICLE, WITH FATTY DEGENERATION OF HEART, ETC.

DR. JANEWAY presented this specimen illustrative of chronic pachymeningitis hemorrhagica, not that the affection was rare, but because he did not recall a case of the kind being exhibited to the Society. The clinical history was interesting with reference to the symptomatology of Bright's disease.

The patient was a male, fifty years of age, admitted to Bellevue Hospital on the 9th of November, 1878. There was nothing of interest about his family history. He had drunk wine and spirits regularly all his life, but rarely to excess. He had had an attack of what was called rheumatic gout in his big-toe-joint and knee some three years previous. For some four or five years he stated that he had suffered from dyspepsia, occasional œdema of the legs and feet and a puffy look about his face. He had had no headache, but had suffered somewhat from dimness of vision for a year or so. He had never suffered from convulsions, nor had he noticed anything special about his urine. He entered the hospital with pneumonia of the middle lobe of the right lung, which soon disappeared under treatment.

He showed a slight œdema of the lower limbs, and his face had a peculiar pale look. The heart showed hypertrophy of the left ventricle and fatty degeneration of its walls, at least that diagnosis was made, because, notwithstanding the percussion and palpation evidences of hypertrophy, the first sound and impulse of the heart were markedly feeble. The urine passed each day varied from fifty to seventy ounces; pale, strongly acid; specific gravity 1010, as a general rule; occasionally a trace of albumen present. Repeated microscopic examinations, twenty to thirty, by Drs. Griswold and Williams, of his house-staff, failed to show casts, and they were capable of making these examinations. The patient was considerably emaciated and weak. He was unsteady, stammering, and hesitating in his conversation, easily losing control over himself. His memory was defective, and he would do things indicating that his mental activity and sense of decency were impaired, such as defecating or urinating on the floor, expectorating similarly, and this notwithstanding efforts to restrain him.

On the 29th of November he had a convulsion, epileptoid in character, though none other occurred subsequently. The urine passed on the day of convulsion had a specific gravity of 1011, and a slight trace of albumen, but showed no casts.

On the 10th of January he was discharged, with his general health considerably improved, but his mental condition remaining in much the same state as described above.

On the 27th of January he returned to the hospital in a dying condition, living only four hours after admission.

The patient had attracted his attention during his term of service—November and December—owing to absence of albumen to any extent, and of casts completely; still, from the character of the urine, its low specific gravity, and its somewhat increased quantity, together with the enlargement of the heart and the history, he was led to the diagnosis of small kidney. The heart he was also led to believe, from the evidence above related, was the seat of fatty degenerative processes. With reference to the mental state he thought that it was possible that the retention of substances, which should have been removed by the

urine, might account, as it sometimes did, for the phenomena.

The post-mortem examination showed the kidneys in a state of chronic interstitial inflammation, with a small amount of urate-infarction in the pyramidal tubes.

The heart showed marked left-ventricle hypertrophy, and fatty degeneration of the muscular fibres of both ventricles, and recent purulent pericarditis.

The right pleural sac contained about a quart of serum, and the right lung showed the middle lobe in a state of recent red hepatization. The lower lobe of left lung was the seat of red hepatization.

The great toe, metatarso-phalangeal joint, had its cartilage encrusted with urates. The knee-joint, however, showed no urate infiltration; but those conditions of the cartilage of the patella and condyles of the femur, which belong to rheumatoid arthritis; erosion, fibrillary state, proliferation of cells, and their fatty degeneration.

The brain illustrates the lesion above-mentioned. The inner surface of the dura mater on the right side was covered by a thin membrane of a mottled reddish to reddish-yellow hue; whilst generally more adherent to dura, it in some places presented portions detached from it, but adherent to pia. The attachment to dura was not firm. It existed in the greatest thickness over convexity of brain, but spread to the base. Microscopically it showed globular and granular orange-colored hematoidine connective tissue and blood-vessels, these latter being large capillaries.

On the opposite side, over the convexity, a very thin membrane was present on the inner surface of dura, of a more punctate pigment character. It, as the other, showed pigment and capillaries.

The appearances characteristic of the disease could be readily appreciated in the specimen, as he had turned the dura mater over, so as to show the new membrane partially detached from the dura on the edge of section.

The brain showed no lesion.

He also deemed this specimen of interest as showing a lesion in a case where mental impairment existed in chronic Bright's disease. The fact of urine of this nature in this case, and hypertrophy of the left ventricle, establishing the diagnosis of small kidney, was no new thing; but he had known it so often forgotten, that he thought it well to lay a little stress on it.

DR. VAN GIESEN asked if there was any sediment in the urine?

DR. JANEWAY replied in the negative, and in this connection referred to the usual causes of rapid decomposition of urine by the latter being contained in old urinals or bottles containing sediment. He always made it a rule to have entirely fresh bottles for purposes of urinary examination, and had had no reason to be dissatisfied with the results.

DR. W. M. CARPENTER thought it generally accepted that the quantity of urine and its specific gravity were more important symptoms in the diagnosis of chronic Bright's disease than the mere presence or absence of albumen and casts. He also referred to a case reported at the last meeting of the State Medical Society, by Dr. W. S. Ely, of Rochester, in which for twenty-two successive days neither casts nor albumen were found in the urine, yet the quantity was large, and had a low specific gravity, and at post-mortem a contracted kidney was found.

DR. BRIDDON stated, that as a rule, he had not found casts and albumen in the urine of patients who had gouty kidney, and that urine of low specific

gravity was much more suspicious evidence of contracted kidney than any other symptom.

MYXO-SARCOMA OF ORBIT—RAPID GROWTH.

DR. C. S. BULL presented a specimen of myxo-sarcoma of the orbit, accompanied by the following history.

Patient was a boy, *æt.* 8. Good family history—good previous history up to Dec. 22d. On that date he slipped, and in falling struck against the curved handle of a door-latch, and received a slight scratch of the skin over the malar protuberance, just below the orbital margin. Nothing was noticed by the boy or his parents until two days later, when the lower eyelid began rapidly to swell. He entered the Eye Infirmary on December 26, 1878, and came under the care of Dr. Loring. At that date the eyelids were almost entirely closed, owing to the great swelling of the lower lid. On pulling upward the upper lid, the eyeball was seen displaced upward and inward against the corresponding orbital wall, and almost immovable. There was no injection of the ocular or palpebral conjunctiva, and the functions of the eye were normal. There was no swelling of the upper lid, and no conjunctival secretion of any kind. The swelling of the lower lid was elastic, as if from a fluid cyst, was not painful, and the swelling could be made out to extend into the orbital cavity. The child was etherized, and an incision made parallel to the orbital margin, and about half an inch below the margin of the lower lid, about three quarters of an inch long, and the knife introduced into the orbit about one and a quarter inch, keeping near the floor of the orbit. There was not much hemorrhage, and no pus was found. The swelling of the lid increased, and the incision was repeated three days later through the original opening, which had partially healed: this met with the same negative result. On the following day the wound began to gape, and a red, bleeding, fungoid mass began to protrude. The protrusion rapidly increased, the upper lid began to swell and become red, and the child began to run down in health. There was no change in the eye. Vision was good to the last, and the ophthalmoscope showed a normal optic disc. The hemorrhage was considerable all the time from the growth, and it was decided to operate. The operation was done January 13, 1879. It was found impossible to remove the growth, leaving the eye in place, so enucleation of the latter was the first step in the operation. The optic nerve was found apparently intact, and microscopic sections showed the nerve to be normal. An incision was then made through the skin of the cheek from the external angle of the lids, downward and inward in a curved line across the malar bone, through healthy tissue, and then upward to a point near the lower lachrymal puncture, thus cutting away about four-fifths of the lower lid. The main portion of the orbital growth was then removed entire with the part that protruded, with great ease. The orbit was cleaned thoroughly by means of scoop and scissors, the entire contents being removed down to the periosteum. The whole orbital tissue was found infiltrated with the growth, which seemed to be adherent to the periosteum mainly at one point, near the outer and lower wall of the orbit. Since the operation, the child has done well. The orbit is granulating from the bottom, and eventually the margin of the upper lid will be brought in contact with the raw surface of the incision below and united by sutures.

The growth proved to be a myxo-sarcoma and very vascular. The extreme rapidity of its growth and the slight exciting cause are the main points of interest in

the case. Another interesting point is the condition of the optic nerve. Though the eyeball was greatly displaced, and the optic nerve put strongly on the stretch, and though a great degree of pressure must of necessity have been exerted upon the optic nerve in the orbit, yet the optic disc never showed any departure from a state of health, and sections of the nerve posterior to the eyeball showed it to be normal.

DR. JANEWAY stated that he had seen myxo-sarcomatous tumors disappear under the use of Fowler's solution given in five-drop doses, *t. i. d.*, for three months. At the same time static electricity was employed. Such results had been obtained in a girl who had ten such tumors scattered over her body. He further facetiously referred to the fact that some tumors, of the same variety, which existed in the brain, could not be reached.

DR. BRIDGON referred to the rapidity with which myxo-sarcomatous tumors returned, and illustrated the fact by a case from which a tumor was removed, and reappeared in the granulations.

VESICAL CALCULI—BIGELOW'S METHOD.

DR. KEYES exhibited four vesical calculi, which he showed not so much for the value of the specimens, or for the peculiarities of the cases, as to put them upon record as the 10th, 11th, 12th, and 13th cases in which he had operated by Bigelow's method. He also took occasion to make a few remarks regarding certain manipulations which he had found to be serviceable.

The first case was that of an old man who had symptoms of stone for two or three years. He was operated upon December 10, 1878. The stone weighed two drachms, and the operation was completed in forty-five minutes. He came to town yesterday, and was well.

The second case was operated upon January 15, 1879. The stone was composed mostly of urates, weighed six drachms, and was removed in an hour and two minutes. On account of a clogging in the water-bottle the operation and evacuation was somewhat delayed. At the end of one week the patient was out walking, and in two weeks left town.

The third case was operated upon January 28, 1879. The stone weighed six drachms, and was composed mainly of urates. The operation occupied thirty-five minutes.

The fourth case was operated upon that afternoon. The patient was a gentleman from Newark, N. J., whom he saw, with Dr. Van Buren, for the first time in January, 1878, and at that time found he had stone in the bladder. The patient afterward came in contact with an irregular practitioner, who promised to dissolve the stone. February 9, 1879, Dr. Wilmarth, of Orange, asked Dr. Keyes to operate upon the patient. It was difficult to make the latter believe that the stone still existed in his bladder. It was easily detected, but was found to have increased but little in size since the last examination. The operation for its removal occupied thirty minutes.

DR. KEYES stated that he had now performed thirteen operations by Bigelow's method, and it seemed to him that each additional operation, each increase of experience in its performance, was an argument in favor of the method. He had not had a fatal case, and believed that Bigelow's method would be the one which would supersede all others for the removal of vesical calculi. In conclusion he called attention to the fact that difficulty was sometimes experienced in removing air from the bladder when it had been accidentally introduced from the wash-bottle. He had

accidentally discovered that by turning the bottle upside down the water rushed in, displaced the air at once, and the latter appeared at the bottom (now top) of the bottle above the water. The bottle then had to be refilled before washing was recommenced.

One advantage to be derived from the use of Bigelow's admirable washing-bottle was stated to be the facility with which the existence of small fragments of stone in the bladder could be detected during the washing by combining auscultation with the washing. The sharp click of the little fragments against the catheter as the water rushed in and out was very distinct. Dr. Keyes had used this method in place of ordinary sounding where a very small stone was suspected. He did not believe the necessity for using very large tubes existed. He had never used any tube larger than 30 French, the average being 27 French, 18 American scale. In over one-fourth of the cases there was no disturbance whatever following the operation, not even a chill. The average duration was three-fourths of an hour. Some patients had been subjected to it who would have died had they been operated upon by the usual methods.

The Society then went into Executive Session.

NEW YORK ACADEMY OF MEDICINE.

OBSTETRIC SECTION.

Stated Meeting, January 23, 1879.

DR. SALVATORE CARO, CHAIRMAN.

SUDDEN DEVELOPMENT OF APHASIA.

DR. CARO gave the history of a case of aphasia as follows. A lady, thirty-two years of age, married, and the mother of eight children; of a nervous temperament, and usually strong and healthy. Her husband, before marriage, contracted syphilis, underwent treatment, and was declared cured by the physician who attended him. He then married. After marriage there was a renewal of the disease, and it was communicated to his wife. Both were then treated, and both were declared cured. Both had a primary sore and roseola. There were no farther constitutional manifestations of the disease. In the month of August last the wife was suddenly seized with aphasia. A physician was called, several remedies were employed, but the woman was not relieved.

Dr. Caro saw the patient in consultation, and to him the husband confessed that he had syphilis many years ago, and that he had communicated it to his wife. It was immediately suspected that syphilis was the cause of the aphasia, and treatment by the use of iodide of potassium was at once commenced. Improvement began at once, and apparently complete cure was effected within a few days. The treatment was continued for a short time, but the patient, becoming tired of it, ceased it altogether. In the month of December a second attack of aphasia occurred. The iodide of potassium was renewed, the aphasia quickly disappeared, but an eruption at once appeared upon the legs. It was thought to be due to the iodide of potassium, and the remedy was discontinued. The protoiodide of mercury was substituted, and the eruption disappeared.

INTERESTING FEATURE.

An interesting feature in the case, as well as in two others, was the following:

The lady was a Canadian by birth and spoke French fluently. But her dislike for speaking French

was so great that she had scarcely used it for many years. When she had her attacks of aphasia, however, the *only words* which she could speak were *French*, and during the first two or three days of improvement she could use no language except the French. After that she dropped the French language entirely and employed the English, as previous to the occurrence of the attacks.

Dr. Caro had noted the same feature in an Italian patient, a man, forty-nine years of age. There was a syphilitic history early in life. The man had had repeated attacks of temporary and almost complete aphasia. The few words to which he could give utterance during the attacks were Italian, although for many years he had so neglected speaking his native language that he had almost forgotten it. It was with him also as with the French lady; in the early days of improvement, after the occurrence of an attack, he employed his native language exclusively.

The aphasia in the last case also yielded rapidly to iodide of potassium. In neither case was there any evidence of cardiac disease.

OVUM WITH MEMBRANES COMPLETE.

DR. BURRALL exhibited an ovum with its membranes complete. The woman had had several miscarriages. She ceased to menstruate on the 13th of September. She did not suppose that she was pregnant. In October she experienced severe pain, which made her suppose that the menses were returning, but nothing appeared.

On the 27th of December she received a slight strain while moving a barrel of ashes. That was followed by slight pain in the back and sanguinolent discharge, alternating with leucorrhœa, which continued until the 13th of January, when she had a chill apparently nervous in character. There were occasional pains in the back, and an anodyne was prescribed. The patient passed a restless night, and towards morning a mass was discharged from the vagina which proved to be an ovum with its membranes complete. The ovum was about three-fourths of an inch in length.

The Section then proceeded to the election of officers.

Dr. Salvatore Caro was elected Chairman, and Dr. Henry E. Crampton, Secretary.

Correspondence.

THE INDEX CATALOGUE OF THE NATIONAL MEDICAL LIBRARY—THE NEW HEALTH BILL.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The session of Congress just closed has been of great interest to the medical profession of the country, and a brief statement of the action taken upon some medical questions will no doubt interest many of your readers.

The printing and binding of the first and second volumes of the index catalogue of the library of the Surgeon-General's office has been authorized by a clause in the Sundry Civil Appropriation Bill, which appropriates twenty thousand dollars for that purpose. As the MS. for this work is ready, it will be sent to press without delay. As great care is necessary in proof-reading to secure the accuracy which is essential in a work of this kind, the printing can-

not be hurried, but it is hoped that the two volumes, each of about 1,000 pages royal octavo, will be completed by June, 1880. Those who are interested in this matter should remember that the succeeding volumes have yet to be provided for by Congress.

The bill providing for the census of 1880 also passed. This bill is of interest to physicians, since it provides for the securing statistics of disease as well as of mortality, and we may fairly hope, under its provisions, to obtain some very valuable data as to the relations of locality, occupation, age, race, and sex to the more important diseases.

Congress also passed a Public Health Bill, which is the bill introduced by Mr. McGowan, of Michigan, with some modifications.

The history of this bill would form a very curious chapter in the history of public hygiene in this country, but it is too long to be given here. Suffice it to say that the bill was supported and approved by the American Public Health Association, and by the great majority of the leading sanitarians of the country. It was opposed by the Marine Hospital Service, and by many of the advocates of a strong, uniform, national system of quarantine. The essential feature of the bill, as urged by its friends, was that the United States ought to encourage and aid State and local boards as much as possible, instead of trying to override and control them. To this end it was proposed that the United States should subsidize properly constructed boards by paying half their expenses, precisely on the principle adopted in the new census law, which provides that when a State, in 1885, shall take a census on the plan of the United States census, the United States will pay half the expenses.

It will be seen that this feature was stricken from the bill, but it is to be hoped that it will be restored in the coming extra session of Congress.

Very truly yours,

JOHN S. BILLINGS, *Surgeon U.S.A.*

WASHINGTON, D. C., March 6, 1879.

New Instruments.

AN IMPROVED APPLIANCE FOR FRACTURED CLAVICLE.

By C. L. PEIRCE, M.D.,

SAN FRANCISCO, CAL.

In his work on "Surgical Operations and Appliances," concerning the treatment of fractured clavicle, Dr. Wales uses the following language:

"The indications of treatment are plain; the shoulder must be carried upward, outward, and backward. The difficulties encountered in the treatment are not that these indications cannot be fulfilled temporarily with suitable bandages, but that sooner or later the apparatus, of any description whatever, will become deranged or loosened while the patient is permitted to move around, as he ordinarily is during the treatment, and thus the object in view—immobility of the clavicle—will almost certainly be defeated."

Twelve years ago, while in general practice in Massachusetts, I realized the painful truthfulness of this statement. I was then called upon to treat the fractured clavicle of a fat little girl two and one-half years old. I consulted the best works on surgery, but with none of the different appliances could the little

arm be permanently kept in a proper position. At last, almost in despair of success, I devised the appliance represented by the accompanying woodcuts. To my great delight, the most perfect results followed—the clavicle uniting without deformity. Since then this device has been frequently tested, not only in my own practice, but among professional friends, and always with the same happy results.

FIG. 1.

The appliance, as constructed for me by J. H. A. Folkers & Bro., of this city, consists of two rings, *b, b¹*, made of rubber tubing, padded and covered with velvet so as to be easily worn. To one of these rings is firmly stitched two strips of heavy elastic ribbon (varying in length and distance apart, according to the size of the rings), and to the other ring is fastened two sets of buckles. A segment of this ring is finished so as to form an axillary wedge (Fig. 2). A strong linen sling with straps and buckles to make it fast, is made to fit the arm, with an opening at the elbow so that there may be no pressure on the olecranon. Strong strips of tape are sewed to the corners of the sling nearest the hand, while on the back part of the sling, just above the opening for the olecranon, a strong linen strap, an inch and a half wide, is stitched. A broader band to encircle the body completes the device, making only four separate pieces in all.

I usually apply the apparatus over the underclothing. The rings being applied (the wedge ring on the fractured side), the shoulders are drawn back as far as they can be comfortably, and made secure by the elastics. Then the sling is buckled on, the arm being allowed to hang vertically beside the chest, as suggested by Dr. Hamilton, the suspensory tapes being fastened to the ring on the sound side, at the right length to allow this. The posterior strap is next passed obliquely across the back and buckled to the ring on the sound shoulder; the elbow meanwhile

should be pressed upward, and this strap fastened so as to take all the weight from the affected shoulder.

Lastly, the broad band is passed behind the oblique strap, through the loops on the arm-sling, around the body, and buckled so as to hold the elbow securely against the side of the chest.

FIG. 2.

This appliance is so easily adjusted that it requires not over five minutes to properly place it upon the patient, is easily worn, causing no chafing. It accomplishes every desired indication at the time of its application, and it cannot possibly "become deranged or loosened," although the patient has free use of the sound arm.

By the use of the strong elastic bands a constant tension is maintained; therefore the relative position of the parts, when once adjusted, cannot be changed. If unelastic bands were used here they would soon stretch, and the adjustment of the fractured parts would be disturbed.

In using my device the surgeon should be sure that the ring for the fractured side should fit closely around the shoulder; for if this ring is too large it will ride over on the fractured clavicle and defeat the desired object.

If this suggestion is carefully observed and the apparatus otherwise properly applied, it will be worn with comfort day and night, underneath the outer clothing, giving free use to the sound arm, and confidence to the surgeon that perfect results will follow. Figs. 1 and 2 represent a front and back view of the device as applied.

SAN FRANCISCO, CAL.

AN ANTIDOTE IN CARBOLIC ACID POISONING is dilute sulphuric acid, which combines with the phenol and forms the non-poisonous phenyl-sulphuric acid. Dr. Senteleben has used it with success. He gave 10 drops, diluted, every hour.

A SUSPENDING APPARATUS FOR POTT'S DISEASE OF THE SPINE.

In the catalogue of H. Windler, of Berlin, published in 1870, there is a plate of an apparatus for extension from the neck and arms in lateral or angular curvature of the spine. Shepard & Dudley have imported one of these instruments, and, as the question of treating deformities by extension is receiving so much attention from the profession at present, a description of an apparatus with the plate may be of

interest to the medical public. In a note from Mr. Windler, dated Oct 12, 1878, he states that the apparatus was originated by Glissen, is mentioned in 1846 in a book written and published by Dr. H. E. Fritz, but without the sling for the arm. Who first added two arm-slings he does not know, but it was in his catalogue in 1870. The accompanying plate is a faithful representation of the sling. It has two compound pulleys, straps, buckles, to raise or lower either the neck-band or the arm-slings.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 2 to March 8, 1879.

KING, WILLIAM S., Lieut.-Col. and Surgeon. His sick leave extended eight months, with permission to go beyond sea. S. O. 53, A. G. O., March 6, 1879.

HYGIENE VERSUS LONG TRAINS.—The municipal authorities of Prague have, at the request of the Board of Health, interdicted the wearing of dresses with trains in the public streets, on the ground that the dust raised by those appendages is injurious to health. In Algeria the clouds of dust raised by the incessant sweeping of the long skirts of the ladies, produce on the legs, when bathed with perspiration, an irritating pruritis and eruptions which are only partially relieved by baths and a scrupulous attention to cleanliness.

MEDICAL GRADUATES OF CHICAGO.—At the recent commencement of Rush College 122 diplomas were bestowed; one was honorary degree. The Chicago College graduated thirty-eight on the 4th inst.; two received the honorary degree of "M.D.," and one that of "Ph.D." The Women's Hospital College had a graduating class of five.

The Rush alumni banqueted at the Tremont House, and reorganized their association. The Chicago alumni banqueted at the Palmer.

One of the graduates of the Women's Hospital College—Miss Moezler—has been successful in winning, by competitive examination, a place as Interne to the County Insane Asylum. This is the first appointment of a lady to a hospital position in Chicago, except where men have been excluded from competition.

THE POPULATION OF THE GLOBE.—The last number of Petermann's *Communications Géographiques* contains fresh estimates of the population of the globe. According to recent researches, the population now numbers about 1,439,137,980 souls. This figure, however, is only approximate to the truth, as in the cases of many countries, particularly China, Africa, Australia, and Polynesia, exact data are wanting. Europe has 312,398,480 inhabitants; Asia, 831,000,000; Africa, 205,210,500; Australia and Polynesia, 4,413,000; America, 86,116,000. It is an average of 500 inhabitants for every square mile of the surface of the globe.

After having estimated the number of men existing on the earth, the German statisticians next turned their attention to the equine race. The number of horses at present existing on the globe, exclusive of China and Japan, seems to be about 58,000,000. Of this number the contingent of Russia is about 21,750,000; that of the United States, 9,504,000; of the Argentine Republic, 4,000,000; Germany, 3,352,000; France, nearly 3,000,000; Canada, 2,264,000; Great Britain, 2,225,000; Hungary, 2,179,000; Austria, 1,367,000; Turkey, 1,100,000, etc.

ACTION OF THE BLATTA ORIENTALIS.—The *blatta orientalis*, or common cockroach, is a popular remedy in Russia. The researches of Bogomolow have given the following results from its employment: The quantity of urine is increased; the quantity of albumen diminished; œdema and ascites disappear; the weight of the body diminishes; the perspiration is generally increased; digestion is not impaired; the kidneys are not irritated. The dose employed was four and a half grains of the powder obtained from the dried insect. These results were confirmed by Unterberger, who employed the drug with great success in scarlatinal albuminuria. M. Kochler has also employed it in thir-

teen cases of dropsy of various origin. His results were sufficiently conclusive, and show that the *blatta orientalis* really possesses remarkable diuretic powers. Its most interesting action, however, is its power to cause a rapid disappearance of the albumen from the urine. Hence it is not a simple diuretic, and its true field of action should be sought in Bright's disease. It seems to be entirely innocuous.—*Jour. de Méd. de Bordeaux.*

TREATMENT OF ULCERS OF THE CERVIX UTERI BY CREASOTIC GLYCERINE.—Dr. Mendelssohn, of Bildah, Algeria, speaks very highly of creasotic glycerine in the treatment of non-specific ulceration of the cervix. His formula is: pure creasote, 2 grammes (ʒ ss.); glycerine, 50 grammes (ʒ xijss.); alcohol, 25 grammes (ʒ vj.). He applies it every day or two to the ulcerated surface by means of a soft brush. He has treated with this application 28 cases of simple ulcer or erosion, 7 cases of fungous and granular ulcer, and 2 of chaneroid ulcers of the first class; 26 were cured and 2 only improved. The average duration of treatment was 12 days, though in two of the cases the applications were continued for 30 days. In 8 of these 28 cases the ulceration was due to metritis with abundant leucorrhœal discharge, and these were the cases which proved most rebellious to treatment. Of the second class, six cases were cured and one improved, the average duration of treatment being 17 days. In the two cases of chaneroid ulcer the treatment was continued respectively for 30 and 40 days, but the results were entirely negative.—*Gazette Obstétricale.*

AMERICAN VETERINARY COLLEGE.—The fourth annual commencement of the American Veterinary College was held March the 5th. at Lyric Hall, before a large audience. The degree of Doctor of Veterinary Surgery was conferred on the following graduates: O. D. Carman, of New York; Charles C. Cattamach, of New York; Thomas J. Herr, of New York; William H. Kleindoff, of Pennsylvania; W. B. E. Miller, of New Jersey; R. A. McLean, of New York; T. B. Rogers, of New Jersey; John J. Smith, of Pennsylvania; Th. Outerbridge, of West Indies.

R. A. McLean secured the alumni prize for the best general examination, the prize of the New York State Veterinary Society for the best practical examination, and the prize for the best examination on surgical pathology. J. B. Rogers received the prize of anatomy, consisting of a case of surgical instruments; and D. Light, of the junior class, was awarded a silver medal for the best anatomical examination. Professor James Law, of Cornell University, delivered the address to the graduates.

MEDICAL DEPARTMENT OF UNIVERSITY OF IOWA.—The Ninth Annual Commencement of the Medical Department of the State University of Iowa took place at Iowa City, Wednesday p.m., March 5, 1879. Fifteen candidates received the degree of Doctor of Medicine. Mr. Fred. H. Little, of Muscatine, delivered the Class Valedictory. The degrees were conferred by His Excellency Governor John H. Gear. The Faculty address was pronounced by President J. L. Pickard. The Medical Department has established a graded course of study, which has been in operation for three years, and is showing most valuable results.

FEMALE PHARMACISTS IN HOLLAND.—In 1865 a Mlle. Tobbe, the daughter of a deceased physician of Zaandijk, Holland, petitioned for permission to inscribe herself as apprentice in pharmacy, but was re-

fused on the technical ground that the existing law employed only the masculine pronoun in speaking of the course of instruction for such apprentices. In the following year, however, a law was passed admitting women as well as men to all the examinations for the degree of pharmacist, and already over one hundred ladies, many of them daughters of country physicians or of pharmacists, have taken advantage of the law, and been inscribed as apprentices in pharmacy. The matriculating or introductory examination that must be passed previous to this inscription is pretty severe. It comprises the Dutch language, arithmetic, latin, the reading and explanation of written and printed prescriptions, the theoretical knowledge of drugs, the recognition of simples by their external qualities, the origin of drugs, their scientific denominations and their synonymes, and the preparation of prescriptions. It is a striking fact, and one not altogether flattering to the stronger sex, that since the above law went into operation, the number of male candidates who failed to pass this introductory examination was, relatively speaking, double that of the rejected female candidates. The female apprentices are much sought after in the larger cities of Holland, and are even to be found in the public dispensaries, where they are preferred to men, on account of their greater habits of order, cleanliness, and exactitude.

TREATMENT OF TAPEWORM.—Fleischmann employs the following method for the removal of *tenia mediocanellata*. No preparatory treatment is required. The child is given a bowl of milk for breakfast, and one hour afterwards ten of the following pills are administered: R. Extr. punic. granat. rec. præp., extr. filicis mar. æther., āā grs. xxxviiij.; pulv. punic. granat., q. s. ut fiat massa, div. in pil. No. 40. The dose of pills is repeated twice, at intervals of half an hour; if one of the doses be vomited, the last ten pills are administered. Between the doses lukewarm tea or lemonade is given to hasten the dissolving of the pills and to counteract nausea, if it should exist. At the end of three or four hours a dose of oil with beef-tea is administered, or, instead of it, half of the following mixture: R. Extr. punic. granat. (or filicis mar. æther.) grs. xxxviiij.; Ol. ricini, mucil. acaciæ, āā ʒ iiss.; aq. menth. pip. ʒ i. M.—*Deutsche Medic. Wochen.*

TREATMENT OF OBSTINATE VOMITING BY SMALL DOSES OF IODIDE OF POTASSIUM.—Dr. Formica Corsi states that he has cured with this drug cases of persistent vomiting that proved rebellious to the usual methods of treatment, and that he has known it to be equally successful in the hands of other practitioners. He cites the case of a woman who was suffering from typhoid fever and was at the same time in the second month of pregnancy. The vomiting resisted all the known anti-emetics. Finally he ordered a teaspoonful, every hour and a half, of a mixture consisting of half a grain of iodide of potassium in three ounces of water. On the following day the vomiting ceased.

Dr. Giné confirms this statement concerning the anti-emetic properties of the drug, and states further, that, when given in doses of one-sixth to five-sixths of a grain per diem, it possesses decided laxative qualities.—*Gazette Obstetricale.*

TREATMENT OF PSORIASIS VULGARIS.—Dr. Tichomiroff reports a case of pronounced psoriasis vulgaris diffusa in a boy ten years of age, that was cured by subcutaneous injections of arsenious acid. The eruption was very marked, and was spread over the entire body. At the commencement of the treatment

$\frac{1}{60}$ grain of arsenious acid was injected daily, and the dose was gradually (every three or four days) increased, until $\frac{1}{4}$ grain was administered pro die. After the sixth injection the scales began to fall off; when about one grain of the acid had been administered the infiltration of the skin began to diminish, and after a few warm baths and inunctions with oil the entire surface of the body was cleared of the scales. Hebra's modification of Wilkinson's salve was then employed in connection with the injections. When about $3\frac{1}{2}$ grains of the acid had been used, no trace of the disease remained beyond a slight hyperæmia of the affected spots. The treatment was then discontinued for fifteen days, and again resumed on account of a return of the disease. Finally, after five months of treatment, during which $4\frac{1}{2}$ grains of arsenious acid had been administered, the cure was complete.—*Allg. Med. Cen. Zeit.*

SULPHATE OF COPPER IN SKIN DISEASES.—Dr. J. Dell Orto (*L'Independente of Turin*) has come to the following conclusions:

1. Sulphate of copper is very useful in diseases of the skin produced by deficiency of nutrition or poverty of the blood, such as pellagra, scrofula, chlorosis, etc.

2. Its trophic action is rapid, constant, and innocent.

3. It is best administered in pills in progressive doses, from one or two to seven centigrammes a day.—*New Orleans Med. and Surg. Journal, Dec., 1878.*

CHOLAGOGUES.—On the authority and experiments of Dr. W. Rutherford, F.R.S., dilute nitric acid, physostigma baptisin, phytolaccin, ammonia benzoate, ammonium phosphate, sodium salicylate, all stimulate the action of the liver. Menispermum and veratrum has a stimulating action upon the intestinal glands only.

CHARCOAL FOR BURNS.—A retired foundryman claims that powdered charcoal—from pine wood is the best—thickly sprinkled over the burned or scalded surface, and renewed as soon as it falls off, is a never-failing, grateful, and speedy remedy. It relieves pain, and heals as if by magic.

DISSECTION.—London is complaining of the paucity of subjects for dissection.

PITURI, prepared from a plant growing in Australia, named *Duboisia Hopwoodii*, is said, by Drs. Sidney Ringer and Murell, to be slightly narcotic and closely allied to atropia, to first salivate, then dry the secretion, and dilate the pupil. They claim that its more prominent effects resemble gelseminum and jaborandi.

BOOKS RECEIVED.

ATLAS OF HUMAN ANATOMY, with Explanatory Text, by Prof. Dr. C. E. Boeck (Leipsic). Containing thirty-eight colored plates of the bones, muscles, vessels, and nerves of the human body, organs of sense—eye, ear, tongue—respiratory apparatus, abdominal and pelvic viscera, organization of fœtus, the teeth, with the genito-urinary organs of the male and female. Folio. Cloth. New York: William Wood & Co., 1879.

WOOD'S MEDICAL LIBRARY OF STANDARD MEDICAL AUTHORS. No. III. A Clinical Treatise on Diseases of the Liver, by Dr. Fried. Theod. Frerichs, Prof. Clin. Med., Univ. Berlin. Vol. I., translated by Chas. Murchison, M.D., F.R.C.P. 8vo, pp. 224. New York: William Wood & Co., 1879.

Original Communications.

ON "RAPID LITHOTRITY WITH EVACUATION"—"LITHOLAPAXY" OF BIGELOW.

WITH A SECOND SERIES OF CASES.

By W. H. VAN BUREN, M.D.,

PROFESSOR OF SURGERY, BELLEVUE HOSPITAL MEDICAL COLLEGE.

IN September last I published in the RECORD six cases of stone in the bladder, treated by the new method. I have now to add a summary of seven additional cases which have since passed through my hands. Their uniformly successful result tends to confirm the favorable estimate already assumed of the superior safety and effectiveness of the American modification of the operation of lithotripsy. The value of Prof. Bigelow's discovery of the hitherto unsuspected tolerance by the bladder of the judicious use of the lithotrite and washing-bottle, when this organ is at the same time entirely freed from calculous matter, is becoming gradually apparent.

In the following cases, which have been taken as they presented themselves in private practice, without selection, there has been no serious reaction in any instance; atony has not been caused, nor aggravated when already present, nor has any serious drawback been encountered. The manipulations have been conducted deliberately and with great gentleness, more attention having been given to entire removal of the fragments than to the time employed, which, as confidence in the new method is gained and facility in detail acquired, can certainly be shortened.

CASE I.—R. M., Esq., *æt.* 63, of New Orleans, consulted me in October, 1877, with a history of atony, requiring the catheter since the previous July, and more recently of bloody urine after horseback exercise. Some vesical irritability since 1850. Examined for stone by Reliquet, in Paris, in 1876, with negative result. I found some enlargement of prostate, and a rough movable stone more than an inch in diameter. Mr. M. could not remain in New York, and was subjected to lithotripsy elsewhere, but never got entire relief, though passing much calculous matter after the several crushings to which he was subjected.

In August, 1878, he returned with very frequent and painful calls, and turbid ammoniacal urine, and I recognized several calculous masses in the bladder by the searcher.

On September 2d seventy-two grains of mixed urates and phosphates were removed in forty-five minutes. The bladder was distinctly trabeculated, and the manipulations were conducted with great care. There was no chill or increase of temperature, and prompt relief followed; the urine became acid and comparatively clear, and the intervals longer. After a final search he left for home on the 12th of September, holding his water four to five hours, having been instructed to evacuate and wash out the bladder in the morning with the borax and glycerine solution, and at night with water acidulated by nitric acid. Subsequent reports have been entirely favorable as to permanency of cure.

CASE II.—F. H., Esq., *æt.* 58, brought by Dr. H. S. Downs, of Bleeker Street, September 28, 1878, with symptoms of stone for the last three years, occurring in paroxysms. Gets up now four times at night; calls more frequent during the day. Urine acid, nearly clear. Stone smooth, hard, solitary. Operation on

October 2d. The stone was caught by the largest Thompson lithotrite, which marked a diameter of one and three-eighths inches, and it required more than my unaided strength of hand to crush it, but it finally gave way with quite a report. After three or four fragments had been crushed, Dr. Keyes completed the operation with his modified Thompson's instrument. Whole time, forty-two minutes; weight of debris, dried, 239 grains of nearly pure uric acid. Mild reaction followed, with some blood and pus in the urine, more frequent calls, and a slight epididymitis. These symptoms subsided gradually after the first week, and entire recovery followed. The patient remains well at this date.

CASE III.—A healthy girl, in her eighth year, was brought to me by Dr. Morje, of East 71st Street, October 3, 1878, accompanied by her parents, who gave an account of bladder symptoms of a year's duration, which occurred in paroxysms; and of a confession by the child that fourteen months before she had introduced a hair-pin into the privates and lost it. I recognized by the searcher an immovable foreign body of some size, which gave the sensation of an irregular calculous mass in the bladder.

On the 9th of October, under ether, the mass crumbled readily in the grasp of a lithotrite, but a long smooth body, the ends of which seemed fixed in the lateral walls of the bladder just within its orifice, remained between the jaws of the instrument, and could not be dislodged without more force than seemed justifiable. Gentle manœuvres with the several instruments contrived for the removal of hair-pins, aided by the little finger in the vagina, failed to free the extremities of the foreign body, and we finally succeeded by forcible traction upon its middle by means of a polypus forceps, in withdrawing a hair-pin of ordinary size, much bent, and still showing traces of phosphatic calculous incrustation. The fragments which remained were then crushed and pumped out by the washing bottle, the urethra having been dilated to admit the evacuating tube. The crushing and evacuation was attended by slight delay, for the bladder was found to be somewhat puckered and distorted in shape by the plastic exudation provoked by the extremities of the foreign body.

The child recovered promptly, without any bad symptoms.

CASE IV.—Mr. J. C. P., *æt.* 57, was brought to the city on the 9th of December, 1878, by his physician, Dr. Frank Paddock, of Pittsfield, Mass., who had recently discovered a stone in his bladder, explaining symptoms of many years' duration, which had latterly become urgent. I made out the existence of atony to the extent of half a pint, and the presence of two calculi, one a half inch in diameter, and another, struck whilst the first was in the jaws of the exploring instrument, a good deal larger. The urine was not very murky, and the kidneys were healthy.

On the next day Mr. P. was etherized, the stones crushed, and 136 grains (of mixed urates) evacuated in forty minutes. There was no chill or febrile reaction, but the urine contained some blood and mucoid pus for five or six days, and at first the calls were quite frequent. After this he improved steadily, and, having been taught to use the catheter and fountain-syringe systematically, returned home on the twelfth day.

On the 11th of February Mr. P. came to the city for a final examination. He was entirely free from pain, holding his water from three to eight hours, and gaining flesh; a careful search of the bladder discovered no calculous fragments. Residual urine about eight

ounces—the same as before the operation. Directed to use tar-water with his daily injection.

CASE V.—Mr. P. J., *æt.* 51, a hyperæsthetic person, with enlarged knuckles, who has suffered from bleeding piles, but is otherwise healthy, has suffered from frequent and painful calls to urinate for four years, and his symptoms are increasing in urgency. Has had numerous attacks of renal colic. Is disturbed three or four times at night and much more frequently during the day.

A large, movable calculus was recognized, and, his urine showing but little pus, and no casts or sugar, he was subjected to rapid lithotripsy on the 15th of January, 1879. The calculus measured an inch and a half, and the bladder was cleared within the hour, the débris, consisting of buff urates, weighing 360 grains. He was unable to pass water for about twenty-four hours, apparently from swelling of the deep urethra, for there was no atony; no chill; temperature reached 101.2, and the pulse 108. The Jaques catheter passed readily. Urine slightly bloody until the 19th, after the first stool. The intervals gradually increased, and pain went away. On the seventh day Mr. J. walked out, and shortly afterwards started on a trip to the South for the benefit of his general health. On the 24th he visited me in improved health. Bladder examined and found free from calculous matter, and not sensitive. No atony. Advised to wash out every other day until the urine becomes bright. Mr. J. sleeps all night, but urinates every two to four hours during the day, mainly from habit and nervous irritability.

CASE VI.—Mr. C., *æt.* 51, sent by Dr. R. J. Carroll, of Red Hook, N. Y., January, 1879. A rather delicate person, much shattered by the constant pain and urgency in micturition, from which he has suffered more than three years, and by the recent use of narcotics. He has had several attacks of renal colic, and his urine, which contains a good deal of pus, is voided with much suffering about every hour. I found a movable calculus, not too large, and an oversensitive but full-sized urethra, and advised rapid lithotripsy. As he preferred to have the operation performed at home, this was done on the 28th of January by Dr. Keyes, assisted by Dr. Carroll and Dr. L. A. Stimson, 260 grains of grayish-pink urates being evacuated in thirty-five minutes. On the 31st Dr. Carroll reported favorably of the patient's condition and progress. There was some bloody urine following the operation, but no serious febrile reaction, and no retention.

CASE VII.—Mr. J. McG., of Newark, N. J., *æt.* 54, first consulted me in November, 1877, for paroxysms of frequent and painful micturition, with pain at the meatus. Rarely gets up at night. Urine clear; sometimes bloody. Prostate rigid and slightly enlarged; a smooth, hard, movable stone detected in the bladder. Lithotripsy advised.

The patient yielded to delusive hopes of cure by medical means, and did not finally submit to operation until urged thereto by Dr. Willmarth, of South Orange, with whose assistance Dr. Keyes, on the 12th of February, 1879, evacuated 127 grains of red urates and uric acid, in thirty minutes. The reports since indicate no trouble after the operation, and the promise of a satisfactory cure.

In the *London Lancet* of February 1st, 1879, Sir Henry Thompson, speaking of the new operation in a reported lecture, confesses "that the proposition to remove a large, hard stone at one sitting is an attractive one," but he recoils at the "large and heavy lithotrites" at first employed by Bigelow. I say at

first, for although the superior advantages of powerful instruments for litholapaxy are recognized, they have since been made much lighter; and Dr. Keyes and I have never used any other than "the comparatively small but strong" lithotrites described and employed by Thompson himself—but modified so as to work successfully for an indefinite time in the bladder without clogging. This great advantage of the instruments employed for litholapaxy in America is passed *sub silentio* by the English lithotritist. He "prefers to employ," as he tells his students, "in every case, two lithotrites alternately, handing the first when withdrawn full of débris to my assistant, who clears it out completely while I am crushing with the other, which, in its turn, is cleaned, and again used." Now, with all respect, I claim that this method, subjecting the parts, as it certainly does, to injury by the repeated withdrawal of a lithotrite full of débris, is inferior to the operation as performed in America. In none of the cases I have here recorded was it necessary to withdraw the instrument in consequence of clogging; and in one of them, where the stone was very large and hard, the Keyes' lithotrite was worked actively and uninterruptedly for twenty minutes, and came out perfectly clean. I have no doubt that the Bigelow instruments are equally efficient in this respect.

Sir Henry's principal objection to the American operation, that the original Bigelow instruments were "enormous and unwieldy" is therefore not tenable; even if it were, it would be fairly counterbalanced by their superiority in not requiring withdrawal for cleaning during an operation.

The length of time consumed in the earlier operations by the new method is also criticised, and justly; but this is not a fault of the operation—rather of the operators; no living lithotritist beside the critic can be held responsible for a dexterity acquired in treating 422 cases of stone by the crushing operations.

In the *Lancet* of the following week, February 8, 1879, the leading editorial is devoted to the subject of "rapid" lithotripsy. The writer, alluding to Clover's apparatus for evacuating fragments from the bladder, says "this practice has not been very extensively adopted. Sir Henry Thompson, for instance, opposed it, except in unusual cases, on the ground that the removal of the detritus by the aspirator caused as much irritation as the crushing by the lithotrite, and that repeated injections, which change rapidly and considerably the volume of the bladder, always irritate the organ."

The writer adds, subsequently: "We confess it was not without some surprise that we found Sir Henry Thompson, in a lecture published in our columns last week, in referring to Professor Bigelow's proposal, saying: 'I am bound to say that my own system has for a long time past been gradually inclining to the practice of crushing more calculus at a sitting, and removing more débris by the aspirator than I formerly did.'" "This," continues the editor, "is an important confession, and involves the abandonment of his old position. For some time to come lithotripsy may be practised under the new and seemingly harsher conditions [of litholapaxy], and months or even years must necessarily elapse before the surgical world can be in possession of sufficient data for a definitive judgment. Meanwhile we shall watch and wait."

It is evident from these quotations that the American modification of lithotripsy is commanding attention abroad; and, in the change of base attributed to Sir Henry Thompson is to be recognized an acknowledgment of the superiority of Professor Bigelow's strategic position.

SOME REMARKS ON TYPHO-MALARIAL FEVER.

By C. B. WHITE, M.D.,

SURGEON, U.S.A.

(Read Feb. 27, 1879, before the Central Ohio Medical Association.)

DR. MEREDITH CLYMER, editor of the American Edition of Aitken's Practice of Medicine, gives this fever the following definition (p. 509, Vol. I.):

"An idiopathic fever of mixed type, caused by a combination of paludal and pythogenetic influences, with marked remissions and exacerbations at the beginning, and, after a variable period, becomes continuous; attended with early prostration, diarrhœa, and subsequently extreme adynamia; the characteristic lesion is enlargement and ulceration of the solitary intestinal glands."

He further explains that this disease first claimed notice in 1862, as the "Chicahominy fever," and occurred among men "saturated with paludal poison, exhausted by over-exertion and insufficient rest, imperfectly nourished, exposed to the action of animal effluvia from the decaying bodies of both men and brutes, and drinking water impregnated with the products of common putrefaction," and that the name was proposed and first used by Dr. J. J. Woodward, U. S. A.

Woodward's "Camp Diseases" (p. 40), speaking of "malarial cachexia," describes it as "manifested by a sallow or yellowish complexion, generally accompanied by more or less emaciation, with disturbed bowels, disordered appetite, yellowness of the conjunctiva, torpor of the intellectual functions, debility, and a disinclination to exertion of every kind."

The same author describes forms of typho-malarial fever in which the malarial, typhoid, or scorbutic elements, severally, may predominate; and on page 79 says:

"These early stages of the disease, moreover, are frequently accompanied by the icteroid hue, the gastric tenderness, the nausea and vomiting of remittent fever." He mentions earlier, "These cases generally begin with a more or less decided chill, followed by fever."

Headland's "Action of Medicines," art. Quinine (p. 357), says:

"Quinine is also serviceable in gout, scrofula, dyspepsia, and other disorders, in all of which other medicines which stimulate the secretion of the bile are more or less applicable. Torpidity of the liver is likewise a usual accompaniment of the various forms of debility, and occurs in intermittent, remittent, typhoid and yellow fevers, in each of which this medicine has been recommended and used with advantage. It fact, it may be said that *in all diseases in which quinine is used, there is a failure in the secretion of bile, and in all diseases in which there is a failure in the secretion of bile quinine is SERVICEABLE.* There appears to be some connection between these two things." [Italicized by present writer.]

It was the writer's fortune to serve with troops in the Southern States of America from 1861, with only slight interruption, to 1868, and he can expressly, from his own knowledge, confirm the statements of Drs. Clymer and Woodward in reference to the fever they treat of. His experience in the Scioto Valley, during 1878, recalls vividly much of our sufferings in 1862, near Richmond, Va. The malarial cachexia and congestion of the internal organs, named by Drs. Woodward and Headland, came upon him so insidiously during the winter of 1877-78, as to warp his

judgment and benumb his intellectual faculties before he was aware of it; and the first case of typho-malarial fever under his care (his own child) died of the disease. Some writers and teachers have endeavored to ignore the existence of a compound fever, typhoid in form and malarial in character; but in the present writer's opinion they are mistaken. They lay much stress on the fact that quinine, in many of these cases, seems to have little or no remedial effect; that proves nothing, for in some cases of congestive chill (plainly malarial) quinine is equally indelicate; in both series of cases the remedy may be administered too late, or there may be at work toxic forces that more than neutralize its good influence. Further than this, quinine, even when administered judiciously and in good time, does not always cure common intermittent fever, recourse being necessary to combinations with arsenic, iron, nuxvomica and salicine, or the use of these remedies severally or combined with simple bitter tonics; removal from the district is sometimes the *only perfect remedy.*

Dr. Headland's statement in regard to internal congestions as caused by malaria is pregnant with suggestive thoughts, and affords a most rational explanation of the icteroid hue of skin, nervous headache, constipation of the bowels, and loss of appetite so constantly noticed in especially unwholesome seasons or in unfavorable circumstances, in certain malarial districts. The old plan was to purge freely in these cases and to use calomel; and even so recent a writer as Waring (Therapeutics, p. 539) says of the action of quinine as an anti-periodic:

"It is necessary to ascertain by careful examination that no hepatic or visceral disease exists; such complications rendering the remedy not only inert, but injurious."

He further quotes Dr. Eyre (Indian Service), "that he often found quinine fail, and that he has never seen it otherwise than injurious when there exists a disordered state of the prime viæ."

While it may not be judicious in cases of obstruction of the bowels to use LARGE doses of quinine, without laxatives to co-operate, still tonic doses, especially combined with tartrate of iron and potash, or the tincture of the chloride of iron and a little strychnia, will never do any harm, but much good in malarial constipation.

A certain proportion of the Chicahominy cases had persistent diarrhœa, and it was noticed that these were less liable to result fatally, unless the discharges were too long neglected and diet unattended to (support being necessary); some of the diarrhœas then contracted, remained for years after, affecting the subjects at irregular intervals, but making the bowels habitually loose and serving their owners a good purpose when exposed to Asiatic cholera and yellow fever (in both of these diseases the writer has found previous constipation a serious complication, and very possibly causing a predisposition thereto).

During the seven days in front of Richmond, in 1862, while there was a strong pressure on medical officers to excuse men from duty for malarial cachexia only, a corporal of artillery reported at sick call, very yellow in complexion, and having headache and constipation of the bowels. By reason of his indomitable courage and devotion to duty he declined being excused, merely wanted medicine, and the next day *died while his battery was in action.*

Similar cases of malarial congestion have been known to the writer, during the past year, in Ohio, *also resulting fatally*, in which the icteroid hue and the constipation were the chief symptoms.

CAUSES FOR THE MALARIAL OUTBREAK OF 1878.

It is a well-known fact that, as various parts of our country have become more thickly settled and consequently better drained, and the houses as well as clothing and diet of the inhabitants more comfortable and better adapted to their needs, malaria, as shown in its concentrated forms of "congestive chill" or malignant intermittent fever, becomes almost unknown; a milder form being substituted, showing itself openly in well-marked chills, with but little interference usually with the nutrition of the subject. Still later in a district's progress, come well-marked enteric fevers, accompanied by the characteristic eruption and bowel symptoms, including frequently severe hemorrhages. But when a mild winter occurs, like that of 1877-78, malaria germs are not destroyed to the usual extent, and with the first warm days of spring alternating with frosty spells, there occurs an outbreak of a low form of fever, accompanied with some inflammation of the air-passages (bronchitis or lobular pneumonia usually), and we have, at a most unusual and unexpected time of year, a disease to contend with, typhoid in form and malarial in character, peculiarly liable to affect children who may be outgrowing their strength or poisoned by unwholesome effluvia around school-houses, and young people exhausted by continuous mental and bodily effort, consequently careless of their diet and peculiarly open to morbid influences, as well as people of all classes reduced in health or weakened in strength. A further addition to the sufferers by this disease are those who, already exposed to malarial influence, meet with some great disappointment that weighs on their spirits and diminishes their vitality; there is probably no disease known, except Asiatic cholera, in which depression of mind so favors the accession.

Some popular writers have wished to claim, on behalf of the dwellers near unsightly and unwholesome piles of animal ordure, collected on farms for fertilization purposes, that their good health is a proof of the harmlessness of such exhalations: this cannot be the case, and the immunity is no doubt due to the larger amount of fresh air obtained in these cases, probably also to the fact that these substances are actually less injurious than the effluvia arising in cities from dejecta of human origin.

To further prove that nothing offensive can be wholly harmless, it seems to be now extensively believed that "hog cholera" is a typhoid fever, brought about by over-crowding, exposure to violent variations of temperature and to the effluvia of the animal's own dejecta; and its effects best combated by better care, separation, and a change of food: a recent newspaper paragraph states that feeding swine affected by it or predisposed to it, with charred or partly burned corn, has had a most excellent result, which seems reasonable, as we know the good effects of charcoal in various affections of the digestive tract.

Since the writer's residence near Columbus he has had occasion to notice the prevalence of south-westerly winds, which blow back into the city the gases contained in the sewers (these latter emptying in a south-westerly or westerly direction into the Scioto River), which is an unfortunate circumstance as affecting local hygiene. Another circumstance peculiarly unfortunate is the damming of the river at Columbus, for feeding certain canals; flowing water absorbs much injurious material, and the more rapidly it flows the better for all living near it. During the civil war our medical officers constantly noticed the benefits of a camp near

a flowing stream as diminishing the effects of surrounding malaria; especially did we find the neighborhood of the turbulent, seething, irresistible masses of the Mississippi River water useful to our health and well being.

Typho-malarial fever does not seem to be so directly infectious as true typhoid fever, but there appears to be no doubt that it is directly promoted and its virulence increased by the presence of sewer gases, decaying matters, defective drains and other unwholesome influences; all such causes had more material and better opportunity for their effects in the following mild winter of 1877-78.

The fruit crop of 1877 was notably a deficient one, and both fruit and vegetables did not keep as well, nor were as wholesome in the mild winter following as in usual seasons; and the spring of 1878 was notably behindhand in bringing us early fruits from distant markets. The fruits of the earth are both useful in acting directly on the bowels and as stimulating, as a relish, an appetite for other articles of diet, and their absence or scarcity must always act injuriously.

PECULIARITIES OF THE RECENT DISEASE.

In 1878 this continued fever often began with distinct chills, marked by repeated perfect intermissions, and in some cases the chills were apparently "broken" by the exhibition of anti-periodic medicine; still, after a variable interval of comparative health, usually three or four days to one week, a low form of continued fever came on, accompanied by moderate delirium, entire loss of relish for food, little thirst, but much heat of skin and derangement of the digestive organs; diarrhoea was not constantly present, not even in the less congestive cases.

In some of these cases abortion seemed to occur, the disease not running a full course; but in others there followed, even after a slow convalescence, sequelæ of continued fever, such as chronic conjunctivitis, inflammations of the joints, and deafness; accompanied with unusual paleness and great debility, as long-continued as after the ordinary enteric fever.

Dr. Woodward mentions the lesions of the bowels as affecting the ileum. During the past year I have noticed ulcerated patches as more usual and more frequent in the colon; perhaps very few spots in the small intestine, and in the large intestine large and frequent ulcerations. I should not give this so important a notice, but on consultation with Prof. Loving of Columbus, a careful and conscientious observer of large experience, he states that he believes ulcerations of the large intestine to be a distinguishing mark of this disease, and exhibited preparations illustrating this pathological view.

PROPHYLAXIS AND TREATMENT.

As a means of guarding against any low form of malarial fever, removal from the locality is probably the best. And in combating such disease, iron in some of its forms, combined with quinine or with arsenic, seems the most efficient preventive. After the occurrence of the disease alcoholic stimulants and easily assimilated food and tonic doses of quinine seem to do the best. To reduce the temperature, should the milder treatment prove inefficacious, moderate doses of quinine, repeated at intervals, should have a fair trial; it does not follow because the exhibition of excessive doses has apparently been injurious, that we should discard this remedy. The opinion of the profession in this country seems to be opposed to the cold pack and cold bath, as recommended by Prof.

Liebermeister in ordinary typhoid fever (Ziemssen's Practice, Vol. I.); but the success of sponging seems to indicate its value, and it seems as if this system should have a fuller though careful trial even in typho-malarial fever.

Except the administration of larger doses of antiperiodics than is necessary in true typhoid fever, the indications for precautions and for support and treatment are the same. It seems to be a disease more controllable by preventives than the ordinary enteric fever, but when it does occur in an unmodified form it has the same deadly and long-extended course as its better known congener.

In treating this disease the practitioner must be on his guard against the long continued fainting-fits that so often occur in it, and strong spirits of ammonia for inhalation and extra quantities of strong spirits of wine (properly diluted) should be kept constantly at hand and the nurse instructed to use them freely. It is not considered possible to give a typhoid fever patient, even if a child, so large a quantity of wine or brandy as to do any permanent harm.

Further, in this great debility and with life hanging as by a thread, the head should not be raised, medications and food being given by spoonfuls or through a tube.

COLUMBUS BARRACKS, OHIO, Feb. 24, 1879.

ANTISEPTIC SURGERY.

By FANEUIL D. WEISSE, M.D.,

PROFESSOR OF PRACTICAL AND SURGICAL ANATOMY, MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

IN the MEDICAL RECORD of March 1st, 1879, appears a well-timed editorial résumé and digest of the present status of so-called antiseptic surgery.

Being firmly imbued with the importance of keeping constantly in mind that germ-laden air produces, by inducing the putrefactive process in a wound, the constitutional sequelæ of surgical fever and septicæmia, I cannot refrain from forwarding to your excellent journal the following reflections upon the analysis of the five methods of antiseptic surgery now in use.

The writer of the article says:

"The two disturbing elements preventing primary union are: 1st. Tension from effusion of blood or serum, causing separation of the edges of the wound. 2d. Inflammation and suppuration, followed by putrefaction and secondary phenomena, which we designate as surgical fever, pyæmia, and septicæmia." In closing, the writer gives this as his conclusion upon Mr. Lister's method: "If we were called upon to decide what was the most important element in Mr. Lister's dressing, we should say that it was his system of drainage, and to this, more than anything else, must be attributed his success."

Free drainage, as a factor in guarding against the first disturbing element, preventing primary union, is self-evident. Of its influence on the second, it seems to me that inflammation and suppuration would be produced by tension of retained fluids—a condition which would undoubtedly defeat primary union; but if these fluids, as effused, were guarded from the access of germs from the air, they would never undergo putrefaction.

I would regard the sequence that occurs leading to the secondary phenomena—no matter what the method of drainage—to be:

1st. Germs from the air obtain access to the fluids effused at the surface of the wound.

2d. The putrefactive process is initiated, and putrid fluids bathe the wound.

3d. These putrid fluids absorbed, the secondary phenomena of surgical fever and septicæmia follow.

Of the agents used in the dressings of the five methods, an antiseptic or germ-killing agent is common to them all; while, in four of the five methods, raw cotton is applied. The efficacy of raw cotton, as resorted to, is due to its preventing the access of germs to the wound, by filtering the air that permeates it, and trapping the germs with which it is laden, upon the fibres of its exposed portion; thus the germs, "falling in a barren place," find nothing in which to set up the putrefactive process.

The *modus operandi* of the five methods practised may be epitomized, as, three ways in which germ implantation at the surface of the wound is prevented: 1st. By the continued application of a germ-destroying agent; 2d. By the initial application of an antiseptic, and the subsequent prevention of the access of germs to the wound; 3d. The continuous application of a germ-destroyer and a germ-trap.

Dr. James R. Wood, in his open method of treatment with the continuous application of a watery solution of carbolic acid and of balsam Peru, fulfils the first; the second is carried out by Mr. Lister, Dr. Guerin, and Mr. Callender; the third is followed by Mr. Gamgee with his continuous dressing of oakum and cotton.

From the present advanced standpoint of antiseptic surgery, I agree with the writer, that we can undoubtedly regard some of Mr. Lister's precautionary measures—such as the spray—as unnecessary. But, we should accord to Mr. Lister the entire credit of having pointed out the way to effect the triumphs in the surgery of to-day. The recognition of the baneful effects of germ implantation from the air on the surface of wounds, and the pointing out, as the indication of treatment, the preventing of the same, must be regarded, with the introduction of the ligature by Ambroise Paré, and the recognition of anaesthesia by Wells, as the three great epochs of surgery.

From the line of argument adduced, it appears to me that the five procedures of antiseptic surgery present no incongruities. They all insure rest to the wounded part, and free drainage therefrom, which militate against simple inflammatory action from disturbance of the part, or tension from retained fluids; and, in the three methods where coaptation of the wound is resorted to, they favor primary union. They also all provide for—what the writer of the editorial means to imply by the word "cleanliness," without according to it its due weight, or explaining its *modus operandi*—the prevention of germ implantation from the air, upon the surface of the wound.

This last indication fulfilled, is the key to the results in common of the five methods, viz.: the successful prophylaxis of putrefaction of the organic matter in the fluids effused from the wound, thus effectually doing away with the only condition that leads to the constitutional sequelæ or secondary phenomena of surgical fever and septicæmia. To the carrying out of this latter indication must be credited the wonderful successes of antiseptic surgery, as compared with the results in the treatment of wounds and surgical operations previous to its introduction.

It is often said, that without antiseptic methods surgeons had in the past similar successes to those of antiseptic surgery. True, but those successes were occasional, not uniform or continuous, and they were not looked for with any degree of certainty. Want of success was explained by "faulty states of the

patient's system," "want of reparative power," etc., etc.

Antiseptic surgery, by preventing putrefaction in the wound, has given a precision to surgical prognosis, by which we with reasonable certainty look for given results. Besides which, it has broadened the field of operative surgery, by enabling us to resort to operations, which, without its protective influence, would be unwarranted, or, at least, would be unwarranted in the light of the statistics of the operations performed in days gone by, when antiseptic surgery was not.

ON THE PERMANENT REMOVAL OF HAIR BY ELECTROLYSIS.

By GEORGE HENRY FOX, M.D.,

NEW YORK.

(Paper read before the Medical Society of the State of New York, February 4, 1879.)

NEXT to our sympathy with the man who cannot raise a beard, comes our pity for the woman upon whom Nature has unkindly bestowed one. Her distress need not be pictured, as there is scarcely a physician present who cannot call to mind some lady who has besought him for a remedy to rid her of hair upon the face. What has been done in such a case? Possibly the various depilatories recommended in text-books on Dermatology have been tried and found to be no more servicable and far more unpleasant than the use of a razor. Possibly an effort has been made to destroy the hairs by inserting hot needles, or injecting acids into the follicles. These means having proved futile, or perhaps harmful, it is possible that a vain attempt has been made to persuade the sufferer that the matter was of little or no consequence, and that cutting the hairs short, or plucking them with tweezers would remedy the evil.

It is quite probable, however, that the statement has been made that *nothing* could be done; and the patient, convinced that something must be done, has finally fallen into the hands of some advertising charlatan, and only yielded to despair after having been thoroughly swindled.

This form of perverted capillary nutrition, which shows itself upon the female face in the form of a promising moustache or beard, is by no means rare. Physicians are not only called upon to treat this, but also the few stiff hairs which are so often seen growing from a small fibrous tumor or pigmented nevus. In both these cases it is evident that destruction of the hair papillæ is the only means of radical cure; and in electrolysis we have, I am convinced, the best, if not the only practicable means of accomplishing this end.

To ophthalmology is due the credit of first employing electricity for the purpose of destroying hairs. Dr. Michel, of St. Louis (Clinical Record, Oct., 1875), recommended electrolysis in the treatment of trichiasis, and employed a method very similar to that which I have found servicable. Dr. Piffard (Diseases of the Skin) speaks of treating two cases of hairy nevus by electrolysis, and in a paper presented to the American Dermatological Society (Aug., 1878), on the treatment of hirsuties, Dr. Hardaway advocated its use. As far as my knowledge goes, this is the extent of the literature of the subject.

The apparatus required for the operation is an ordinary galvanic battery, with a needle or fine wire attached to the negative electrode, and a sponge-tipped positive electrode, which should be applied to

the skin as near as convenient to the field of operation. In my first attempts I introduced into the follicle a fine cambric needle, wound to within a quarter of an inch of the point, with a copper wire which joined it to the negative cord of the battery. This simple contrivance will answer the purpose, although a better substitute I have found in a fine flexible steel needle, used by dentists in extracting nerves. This needle, together with a convenient handle or holder, can be obtained from any dental-instrument dealer, and is readily attached to the battery cord.

In many cases where the hair follicles are large, as they are apt to be upon the cheeks, a fine platinum wire is superior to any form of needle. It can be filed to a point by means of a jeweler's file, and by virtue of its flexibility it will reach the bottom of the follicle (the hair having been previously extracted), while a stiff and sharp needle would pierce the follicular wall and fail to reach the hair papilla. In fact, whenever a needle is employed, the direction of the hair must be carefully noted or the needle will certainly go wide of its mark and fail to accomplish the destruction of the hair. On the other hand, a fine, soft, flexible wire will follow the course of the follicle in some instances, as a soft rubber catheter follows the curve of the urethra in its introduction into the bladder. Where, however, the follicles are naturally small, as about the neck, no matter how coarse the hairs may be, the soft wire will either bend upon itself or pierce the wall of the follicle and go in a wrong direction. In such a case it is better to use the stiff needle and introduce it in the direction of the supposed site of the papilla.

In operating, a strong light is essential to success. The patient should sit by a large window and preferably in the sunlight. Where the hairs are numerous and the follicles small, the eyes of the operator soon tire, and a séance of more than a half or three-quarters of an hour is apt to become both unpleasant and unprofitable. The use of a lens has been recommended, but as both hands are generally employed in the operation, I cannot see how it could be conveniently used unless fitted to the eye.

The extraction of the hair should precede the introduction of the needle or wire, in all cases where the follicle is of large size. In case of fine hairs, however, it is unadvisable. Often when a fine hair is extracted it is not an easy matter to see the mouth of the follicle. If the light is at all dull or the eye fatigued, the follicle from which the hair has been extracted, is lost, and there is little certainty of introducing the needle at the right point. Moreover, if the hair be allowed to remain, tension upon it will usually reveal the direction of the follicular portion, and the needle introduced at the mouth of the follicle and pressed down into the skin as near to the hair-root as possible, will be far more apt to reach or approach the papilla than as though it had been introduced into the follicle after the extraction of the hair. Upon the cheeks and chin, where the skin is thick and the follicles slightly patulous, I have found it convenient to use the soft platinum wire *after* removal of the hair. Beneath the chin, however, and upon the neck where the skin is comparatively thin, I prefer to use the stiff, yet flexible needle, introducing it *before* removal of the hair. There is one advantage lost by removing the hair before the introduction of the needle. We have in that case no test of the successful result of the electrolytic action. On the other hand, if the hair be not extracted at the outset, we can judge of the effect produced by the electrolysis. If the hair comes out when pulled very

gently, it is probable that the papilla is destroyed, but if upon traction with the epilating forceps it seems to be as firmly rooted as at first, it is a proof of the inefficacy of the operation, and suggests a re-introduction of the needle and repetition of the electrolysis.

As regards the strength of the current to be used, no absolute rule can be laid down. The stronger the current, the more rapid will be the effect and the greater will be the pain. From five to ten cells of the ordinary zinc and carbon battery may be used, the number selected being dependent upon the susceptibility to pain and the courage of the patient. In no case can the hair papilla be destroyed without some pain, and the patient will naturally stand a trifle more when there are only one or two hairs to be destroyed, than when there are several hundred. The current must be strong enough to cause decomposition of tissue, which will be manifested by the escape of fine bubbles or froth, by the side of the needle at the mouth of the follicle. When the patient is not particularly sensitive, a sufficient number of cells may be employed to produce this peculiar frying of the tissue immediately after the commencement of electrolytic action. With a weaker current this escape of bubbles may not be noticed until a few seconds after the completion of the circuit.

The first effect of the operation is to produce a small whitish elevation around the mouth of the follicle; in fact an urticarial wheal. After a protracted sitting, the part operated upon will be acutely congested and somewhat swollen, and the number of hairs operated on can usually be determined by gently passing the finger over the skin and counting the number of small lumps resulting from peri-follicular exudation. On the following day the diffused congestion will have disappeared and left a number of red papules or small pustules at the mouths of the follicles. These quickly disappear, and we have only to wait patiently for a few weeks to determine how many hairs have escaped destruction. Without an unusual amount of skill and practice on the part of the operator a certain number are almost sure to grow again, and of course the operation must be repeated until all are destroyed. When there are but one or two strong hairs growing upon the cheek from a small hypertrophic naevus, both the hairs and the "wart" from which they spring can be easily destroyed by a single operation, but when a patient has several hundred scattered hairs growing upon her cheeks and chin, successful treatment will require much time and patience. The soft, downy hairs which often grow luxuriantly upon the upper lip and cheeks of certain women, are not amenable to treatment, and fortunately, these are not incompatible with female beauty. But whenever the hairs grow long and strong and dark, producing a serious disfigurement, it can be safely asserted that they may be permanently removed by means of electrolysis.

A CASE OF ACCIDENTAL SCALPING.—M. Hallez reports the case of a young girl, whose entire scalp was torn off by some revolving machinery in which her hair was caught. The bones of the skull and some of the cervical vertebrae were laid bare, and both ears were torn off. The wound was treated by occlusion. The pain was slight, and the general symptoms were not grave, and the entire surface became covered with granulations. Two months after the accident, however, a series of hemorrhages set in, and the patient died of anemia.—*Gazette des Hôpitaux*.

A GIANT BIRTH—THE CHILD WEIGHING TWENTY-THREE AND THREE-QUARTERS POUNDS.

By A. P. BEACH, M.D.,

SEVILLE, OHIO.

At the request of many readers of THE MEDICAL RECORD I am persuaded to report a case of labor which I attended a few weeks ago. The great size of the child at birth was the remarkable feature of the case, it being probably the largest human birth on record. It perhaps would be well to state here, that when we take into consideration the immense proportions of the parents, the size of the child need not astonish us. The mother, Mrs. Captain M. V. Bates, whose maiden name was Annie Swan, of Nova Scotia, stands 7 feet 9 inches in height. Captain M. V. Bates, formerly of Kentucky, is 7 feet 7 inches in height. These large people have, undoubtedly, been visited by many of the readers of this journal, as they have given public receptions in nearly all of the large cities and towns of Europe and America.

At 12 m., January 15, 1879, I was called upon to attend this lady in confinement, it being her second labor. I found her surrounded with competent attendants, and everything in order and at hand that would in any way add to her comfort and convenience. Her pains were quite infrequent and light. After a convenient time, with my patient in the usual position, I proceeded to make an examination, but was unable to reach the os uteri, it being so far up. I could not with my hand, by any ordinary effort, make a satisfactory examination, but concluded that she was in the initial stage of labor. She remained in much the same condition for the next 24 hours, passing the night comfortably, and I saw no necessity for any interference with the order of things. At the end of 36 hours the pains became more frequent, and on examination I found the os dilating and labor progressing favorably. The head engaged; position, second occipito-anterior. Notwithstanding the long interval between pains the head made good speed through the great depth of pelvis. At 4 p. m., on the 18th, while conducting an examination during pain, the membranes gave way spontaneously and the amniotic fluid came pouring out so profusely as to startle every one. I had my patient very close to the margin of the bed, as was necessary in order to facilitate manipulation on account of her great size.

The bed was well protected with rubber blankets, which carried the waters over the side of the bed, where they were caught in vessels to the amount of five gallons. That lost by absorption and evacuated with succeeding pains, would make the total of water not less than six gallons. This was, undoubtedly, a case of dropsy of the amnion, co-existent with general dropsy, from which she suffered to some extent during the last months of pregnancy.

Soon after the rupture of membranes the fetal head was disengaged, and in the soft parts. The mother was in good condition, the fœtus seemed strong and healthy, and everything indicated a speedy and successful termination. But here the trouble began. After the escape of the waters all pain ceased. The great abdominal muscles which had been so much distended lay lax over the fœtus like the blanket which covered the person of the mother.

Inertia was complete. There was no pain except as the result of manipulation. Ten grains of quinine, Squibb's ergot, and brandy were administered. The forceps were resorted to early, but all to no pur-

pose. The forceps could not be successfully applied because of the unusually large head which lay, with the neck, in a vagina that would measure on its posterior aspect 12 inches at least, and from 7 to 9 in its anterior. The safety of the child was my great fear. The head was seemingly almost born, but the shoulders were fast. How to disengage them was the question. The hand could not be passed to reach the shoulder. I had telegraphed for Dr. J. D. Robinson, of Wooster, O., who now came to my assistance. He attempted the use of the forceps with but little success. The child could not be so delivered. After further consultation, as it was our great desire to deliver if possible without mutilation, we passed a strong bandage over the neck of the child, and while one made downward and lateral traction, the other, after several attempts, succeeded in bringing down an arm, and finally after a laborious siege we succeeded in delivering our patient of a male child. It weighed 23 $\frac{3}{4}$ lbs.; its height, 30 inches; breast measure, 24 inches; breech, 27 inches; head, 19 inches; foot, 5 $\frac{1}{2}$ inches in length. The secundines, which were soon removed, weighed 10 lbs. The mother was considerably exhausted, but is making a good recovery. Mrs. Bates, six years ago, gave birth to a dead child in London, weighing 18 lbs., and 24 inches in height. She was attended at that time by one of the celebrated obstetricians of that city, who encountered the same difficulty in delivery that I had.

[We believe that this is the largest infant at birth of which there is any authenticated record. Cazeaux refers to one that weighed 19 pounds. There is a fœtus in the London Hospital Museum 24 inches long. The average length is 20 inches; average circumference of head 13 $\frac{1}{4}$ inches. The placenta usually weighs $\frac{1}{4}$ th as much as the fœtus. In this case the secundines in all weighed nearly half as much as the child.—Ed.]

Reports of Hospitals.

NEW YORK STATE WOMAN'S HOSPITAL.

SERVICE OF DR. NATHAN BOZEMAN.

(Reported by DR. RUDOLF TAUSZKY, N. Y.)

CASES OF OVARIOTOMY.

SINCE May last, Dr. Bozeman has performed five ovariectomies, all resulting in recovery. In three of the cases both ovaries were removed. Dr. B. attributes his success (100 per cent. recoveries) to the following points: 1st. If the operation can be safely delayed for a week or more, after coming under treatment, he prepares the patient by administering to her tonics and food as much as she can bear. Iron he considers a most valuable agent in the preparatory stage of the treatment. 2d. The antiseptic method (Lister's) he invariably uses in this, as in all major operations. He thinks his successes are greatly due to the means thus adopted of preventing peritonitis and septicæmia. 3d. The treatment of the pedicle; whether long or short, he returns it into the peritoneal cavity. The doctor transfixes and ties it, right and left, several times with wax, carbolized, strong silk ligatures, and claims that there is no necessity of using clamps or Koeberle's serre-neud. 4th. He includes the peritoneum into his sutures when closing the abdominal *incision*, which he never makes larger than is necessary in the median line. Carbolized silk

sutures are also used for closing the wound as for tying the pedicle. Beef-tea, milk and eggs constitute the food given as soon as the patient has fully recovered from the anæsthetic (ether being used for this purpose). If there is a tendency to vomiting, the food is administered per rectum. Quinine and opium the doctor considers of the highest importance in the after-treatment, given in full doses, as being anti-periodic, and a preventive of peritonitis. Should there be an undue elevation of temperature, not controlled by the medication enumerated, Kibbes' cot comes into requisition. The first incision he never makes larger than is necessary for the introduction into the peritoneal cavity of his abdominal spatula, as the doctor terms it (a flexible, metallic rod, 10 to 12 inches long, well rounded off, with a triangular-shaped termination at either end, like Nott's vaginal depressor), about one inch long, also well rounded off. The size of the tumor, its adhesions, if there be any, are thus explored with the aid of this spatula. The incision is then enlarged to 4-6", for the purpose of introducing the hand and separating the adhesions, if their presence has been made out, in the mode above described. The next step consists in tapping the cyst or cysts with Spencer Wells's trocar. In multilocular cysts he taps one cyst after the other through the opening made in the first cyst, and so on, the patient being turned on her side. The cysts are thus emptied to a size sufficient to pass his right hand through the abdominal opening into the peritoneal cavity while drawing out the cyst or cysts with his left. This simultaneous use of both hands Dr. B. considers of the utmost importance while drawing out the cyst. The right hand introduced inside the cavity completes the separation of adhesions that may have remained after the use of his spatula, and also guards against any undue stretching or possible rupture of the intestines, gall-bladder, etc., with which there may be adhesions. The omission of this precautionary measure doubtless has caused many fatal results that might have terminated favorably had this precaution been practised. 6-8 grs. of quiniæ sulphate and twenty-five drops of the liquor opii comp., administered per rectum, are the doses of these remedies used from the first for the purposes mentioned. The use of hypodermic injections are being avoided by Dr. B. After ovariectomy, he is of the opinion that on account of the pain thereby produced, the patients abhor them, and thus cause undue nervous excitement. Dr. Bozeman never uses drainage tubes through Douglas's cul-de-sac, but prefers to draw off effusions by means of tubes introduced through the abdominal opening, reaching down to Douglas's cul-de-sac.

Dr. Bozeman performed his first case of ovariectomy in 1865, also successfully, making in all six cases, wherein nine ovaries were removed. The first operation he published September 1, 1866, in THE MEDICAL RECORD, under the title, "Remarks on the History of Ovariectomy," and the report of a case in which the intraperitoneal treatment of the pedicle with the silver ligature was adopted with success. As stated above, Dr. Bozeman now uses only waxed carbolized silk, both for tying the pedicle and the abdominal wound.

A CENTENARIAN.—The oldest woman in Vienna died on October 16th. Her name was Anna Suda; she was born in Bohemia on March 29, 1767, and had consequently reached the uncommon age of 111 $\frac{1}{2}$ years. During the last two years of her life she was perfectly blind and imbecile.

Progress of Medical Science.

THE ACTION OF DUBOISINE.—Duboisine, the active principle of *Duboisia myoporoides*, an Australian shrub, is a drug which is contending for the place of atropine in ocular therapeutics. A case displaying its powerful action is related by Dr. W. W. Seely, in the *Cincinnati Lancet and Clinic* for February 15th. He instilled three or four drops of duboisine (gr. iv. to $\frac{3}{4}$ i.) into the eye of a patient, taking no pains to prevent its passing into the throat. The same patient had used a four-grain solution of atropine for some weeks, with only local effects. In five minutes after instillation of the duboisine the pupil was dilated, the accommodation paralyzed, and the patient was complaining of great faintness. In fifteen minutes the faintness began to improve, but the patient felt very drowsy; slight dryness of the throat was present. The face was not flushed, and the pulse was normal. In an hour and twenty minutes the patient was able to walk home, though still feeling sleepy. The next day there was marked oral and faucial dryness, but on the third day the patient felt well, and the pupil was normal. The points in which the drug differed from atropine in its effects were, 1st. The vertigo or faintness; 2d. The sleepiness, which was, however, rather stupor than sleepiness; 3d. The late appearance of faucial dryness; 4th. The apparently negative effects on the pulse; 5th. The absence of flushing of the face.

CHLORALISM AND ALCOHOLISM.—An entirely new series of symptoms is said by Dr. G. D. Griffith to be the result of the prolonged use of chloral for alcoholism. His observations would indicate that the drug may produce a condition akin to that for the cure of which it is given.

Among the first symptoms are pains in the extremities, like those of muscular rheumatism, for which they are generally taken. The drug being continued, the mind becomes affected. It is first weakened, the patient is restless and irritable, and finally has attacks of acute delirium. At this time the face is congested, the eyes blood-shot, the throat red; there may be nausea and vomiting; in spite of large doses the patient sleeps but little. These symptoms end in intense nervous prostration, and perhaps death. They simulate alcoholism, but will only cease when the chloral is discontinued. For distinguishing whether the patient is suffering from chloralism or alcoholism, the withdrawal of the drug is the most efficient means.—*The Practitioner*, Feb., 1879.

ARTIFICIAL VESICO-VAGINAL FISTULA FOR THE CURE OF CHRONIC CYSTITIS.—Some time ago Dr. M. A. Pallen presented the records of eight cases in which he had tried this method in the treatment of cystitis with very good results. The operation has since been endorsed by other gynecologists.

In his paper on the subject, Dr. Pallen insists first upon the necessity of a careful diagnosis between urethral and vesical trouble. To insure this, he himself always employs dilatation of the urethra and physical exploration with finger and speculum.

In regard to the cases appropriate for this extreme measure of treatment, there are many milder forms of vesical trouble which do not need it. In these, replacement of the uterus, and operations upon the anterior vaginal wall or perineum, with suitable medication, may be sufficient. When chronic cystitis

proper, however, is found to exist, there is but one remedy, and that is long-continued and absolute bladder rest; and kolpo-cystotomy, or the formation of a vesico-vaginal fistula is the only way in which this can be secured. This operation is best performed with the Paquelin thermo-cautery, heated to a red heat only, as this prevents hemorrhage and subsequent union. The opening must then be kept patent for months, by tubing or glass buttons if necessary, the bladder being daily washed out with warm demulcent fluids. It is rare that any medication is needed. In this way spasm, irritability, and irritation gradually disappear, and when this is accomplished, the fistula is sewed up and the patient cured.

A STUDY OF THE SO-CALLED TENDON-REFLEX PHENOMENA, BY W. R. GOWERS.—This paper embodies the results of observations, made upon three hundred patients, on the nature of knee-reflex (contraction of the quadriceps extensor upon striking the ligamentum patella, usually absent in ataxia, and excessive in lateral sclerosis) and of ankle-clonus (clonic movement at the ankle-joint from sudden dorsal flexion of the foot in lateral spinal sclerosis). Gowers regards the knee-phenomenon as a spinal reflex for the following reasons, viz.: its loss in spinal disease, its arrest by section of the crural nerve, its radiation to the other leg in animals (which he has observed in several cases in man), and, lastly, the results of a study of the movement with the myograph. By this instrument Gowers found that the interval from the tap upon the tendon to the production of the reflex varied from .09–.15 second, which corresponds to the time necessary for the production of a spinal reflex action. The question as to the origin of the afferent impulse in the tendon, or in the muscle (by sudden tension), has been left undecided by the writer, though he leans towards the latter view. The reflex is arrested by damage to the posterior nerve roots (as in locomotor ataxia), disease of the gray matter (as in muscular atrophy), and in lesions of the anterior roots (as in old meningitis); it is also lost in advanced pseudo-hypertrophic paralysis. Its occasional persistence in locomotor ataxia is connected with slight damage to the posterior root-fibres.

Forty tracings of the ankle-clonus were made, and it was found that five to seven contractions occurred per second; during the intervals the relaxation of the muscle is incomplete. A similar clonus may often be obtained from the adductor pollicis of the foot. Ankle-clonus does not appear to result unless the stimulus acts upon the muscle, since it cannot be excited by a stimulus applied to the tendon, unless its tension is increased, and the muscle therefore acted upon. Furthermore, a lateral tap on the tendon will not produce it if the tendon is supported on the other side; on the other hand, the initial contraction can be excited by tapping the muscle. Gowers does not believe ankle-clonus to be of a reflex nature, for the following reasons: he has found that in cases in which the ankle-clonus can be obtained, a tap on the anterior tibial muscles, during passive dorsal flexion, excites contraction in the calf muscles, which does not occur when the tibia is tapped, and so cannot be the result of increased tension. The interval between the tap and the contraction was found to be only .03–.04 second, and therefore insufficient for conduction to and from the cord; the stimulation of the muscle must therefore be direct. Other measurements show that in lateral sclerosis the interval between the tap on the tendo-Achilles and the resulting contraction is .025–.04 second, quite insufficient for a reflex. But the extreme irritability

to local stimulation, excited by tension, may be reflex. Tension on muscular fibres causes an afferent impression, and traces of the clonus show that the irritability is not developed instantly on the tension being put on, but after a period long enough for a reflex. Hence we understand why, though local in its nature, it occurs in spinal sclerosis.

The intervals between the contractions of the knee-clonus bear the same ratio to those of the ankle-clonus as does the interval between the tap and isolated contraction of the knee-reflex to the interval between the tap on the Achilles-tendon and the calf contraction. Hence each contraction in the knee-clonus is probably reflex, excited by the sudden tension of the muscle from the effect of the preceding contraction. In the calf and great-toe muscles the sequence of tension and contraction occurs at each step in walking, and a reflex between the two is probably acquired in the act of learning to walk. A reflex relation between tension and contraction probably plays an important part in the co-ordination of often-repeated movements, and its loss may be part of the pathological state in locomotor ataxia. The ataxic and the child learning to walk may thus be similar in this respect. If this view of ankle-clonus be correct, it should also be a normal phenomenon. The tracings showed that the ankle-clonuses in four healthy individuals had the same uniformity and time as in disease.—*Lancet*, Feb. 1, 1879.

DISEASE OF THE SPINAL ACCESSORY NERVE, BY DR. ALTHAUS.—The patient was a married lady, *æt.* 53 years, in whom incessant spasm of the left sterno-mastoid and trapezius muscles had come on, apparently from anxiety. Muscular rest was only obtained during sleep. The patient was unable to follow her usual occupation, and the general health suffered. Treatment consisted in the application of the voltaic current to the affected nerve, the internal use of bromide of potassium, cannabis indica, and belladonna, subcutaneous injection of arsenic and morphia, and external use of chloroform liniment; this treatment was ineffectual, although some temporary relief was obtained. Dr. Althaus had found treatment unsuccessful in other cases which had come under his notice; he suggested stretching of the spinal accessory, in obstinate cases, in which the patient was determined to seek relief. Dr. Poore, in his work on electricity, records a case which he believes was cured by galvanism. In one case a portion of the spinal accessory nerve was excised by Mr. Rivington. The sterno-mastoid was set at rest, and the head assumed its normal position, but the patient unfortunately died from septicæmia.—*Trans. Clinical Society of London*, Jan. 24, 1879.

SPINAL CORD FROM A CASE OF INFANTILE PARALYSIS—DR. F. TAYLOR.—A child, *æt.* 3 years, had suffered from infantile paralysis involving the left leg from the age of fifteen months. The patient died of broncho-pneumonia. Post-mortem: The muscles of the left leg were extremely pale and of a soft consistence. A transverse section through the lumbar region of the cord showed a slight diminution in size on the left side, the left anterior roots of the lumbar nerves being also smaller. Microscopically, it was found that there was almost complete absence of motor ganglion-cells in the left anterior horn; the large groups normally present in the centre and outer border were entirely absent. A few cells remained in front, but they were small, with few processes, and pale in color. The basis-substance of the gray matter presented a uniform, felt-like appearance, from a close matting together of very fine fibres. The ves-

sels, especially the capillaries, were much less numerous than in health. The antero-lateral column near the gray matter was much denser than normal, the nerve-tubes smaller, and the connective tissue bands more abundant. The anterior nerve-roots were mainly composed of white fibrous tissue. They contained a few nerve-fibres, but only about half the size of those seen on the right side.

Although there had been no palpable weakness in the right leg, yet the right anterior cornu contained too few ganglion-cells as compared with a healthy cord.—*London Path. Soc.*, Feb. 4, 1879.

A VEGETABLE PEPTONE-ALBUMEN SOLUTION FOR THE USE OF THE SICK.—Dr. Franz Penzoldt, of Erlangen, prepares from pea-flour, by means of pepsine and salicylic acid, a vegetable peptone solution which he has found by clinical experience to possess great practical value. He recommends it as a supplement to, not as a substitute for, Leube's meat-solution, over which, however, it possesses the advantages of being much less costly and less troublesome to prepare, and of being very agreeable to the taste. The method of preparation is very simple: 8 oz. of finely powdered pea-flour, one quart of water, 15 grains of pure salicylic acid, and $7\frac{1}{2}$ grains of pepsine (it is most important that this last should be of an excellent quality) are thoroughly mixed together, and then left in a warm place (not above 100° F.) for twenty-four hours, during which time the mixture must be frequently stirred. It is then filtered through thick linen, which retains the starch, and the peptone-albumen solution is obtained. It has the appearance of pea-soup, and a delicately sweetish taste. The salicylic acid was at first added, in Dr. Penzoldt's preliminary experiments, to prevent the fermentation that sometimes occurred; but he soon found that it could be substituted for the hydrochloric acid, as it possessed fully as much, and perhaps more, digestive activity.

Before the solution is used it should be gently heated over a water-bath, and at the same time it may be reduced somewhat in volume, so that only enough to fill two soup-plates, a sufficient quantity for one day, remains. In warming, a portion of the albumen separates in the form of small flocculi, and a thin, mechanically unirritating pap is formed, which contains the peptones in solution. Salt must be added to it in proper quantities, and it may be flavored to taste with root and fruit extracts, Liebig's extract, etc. Dr. Penzoldt reports several cases in which this solution acted very satisfactorily, among them being some cases of ulcer and catarrh of the stomach, and one each of dysentery and diabetes. In all the cases it was well borne, and the patients took it willingly, and improved on it. It seems to be applicable more especially in cases of gastric ulcer and of chronic catarrh, dilatation, and carcinoma of the stomach, but also in cases of chronic catarrh of the intestines, dysentery, convalescence from typhoid fever, anæmic conditions with weak digestive powers, diabetes, etc.

The same solution may be employed as a nutritive enema; only in its preparation for this purpose the pancreatic ferment must be substituted for the pepsine. The following is the formula for it: 8 oz. of pea-meal, 1 pint of water, 15 grs. of salicylic acid, and 10 drops or more of pancreatine-glycerine; mix well, and allow it to stand for several hours to a day in an ordinary temperature. During this time some peptonization takes place, but no sugar is formed. The fluid is then simply poured off, a little of the meal being allowed to go with it, and the nutritive

enema is ready. There will be about enough for two clysters, which may be administered with any ordinary syringe. In the rectum more peptones and some sugar are formed, and in favorable cases are entirely absorbed. The injection is, as a rule, well retained. One patient, a phthisical man, retained it for four hours, and asserted that he experienced a feeling of contentment after it. After four hours he passed some feculent masses, in which no peptone-reaction could be demonstrated, although the injected solution presented this reaction very distinctly.—*Deutsche Med. Wöchen.*, Nos. 33 and 34, 1878.

PARTIAL EXCISION OF THE DESCENDING COLON FOR THE EXTIRPATION OF A TUMOR.—Prof. Gussenbauer was recently consulted by a man who had presented for a week all the symptoms of a complete intestinal obstruction. He could take no nourishment, and suffered from intense pain, eructations, and incessant hiccough. Injections and catheterization showed that the obstruction was seated in the descending colon, and manual exploration by Simon's method revealed a tumor as large as a fist, almost completely obliterating the colon, and adherent to the small intestines and the mesentery. Despite the unpromising nature of the case, Prof. Gussenbauer determined to extirpate the neoplasm. He made an incision in the linea alba, and another running outward towards the lumbar region, punctured the coils of intestine, and got down to the tumor, which he dissected out with the scissors and his fingers. In this manœuvre the small intestine was opened, but the wound was at once closed with a catgut suture. Finally the large intestine burst open, and its contents escaped into the peritoneum. The operator then at once excised a segment of the colon, including all of the tumor he had been able to dissect off, and united the two ends of the gut by sutures. The peritoneum was then carefully cleansed, and the wounds closed. It is perhaps unnecessary to add that the patient only survived the operation a few hours.

A similar operation was performed many years ago by Reybard (*Gazette Méd. de Paris*, 1844). His patient recovered in thirty-eight days, but died ten months later of a recurrence of the tumor.—*Lyon Médical*, Jan. 26th.

SUPRA-ORBITAL TIC CURED BY AN INJECTION OF CHLOROFORM.—In this case from six to twelve drops of chloroform were injected into the upper eyelid, the point of the needle being directed toward the supra-orbital foramen. The operation was followed by severe pain, which was succeeded by insensibility of the entire region. A tumefaction of the region was also produced, which was replaced by an induration that persisted for several days. In spite of the obstinacy of the affection, a single injection gave relief for several months.—*La France Médicale*, Dec. 11, 1878.

ON THE SELECTION OF AN OPERATION FOR STONE IN THE BLADDER.—In an article upon this subject, Mr. Teevan lays stress upon the advantages to be derived from first crushing the stone and then removing the fragments through an incision, as for external urethrotomy. By this means he claims to avoid the high mortality of lithotomy, and the intractable cystitis so often induced by the repeated manipulations of lithotripsy. After reviewing the several operations and their applicability to different circumstances, he sums up his conclusions as follows: 1. Lateral lithotomy is specially indicated for the removal of all

stones from males under puberty. 2. All calculi in men ought, if possible, to be crushed. 3. Stones in the border-land, between lithotomy and lithotripsy, may well be disposed of by lithotripsy and external urethrotomy. 4. Calculi within the legitimate range of lithotripsy, occurring in patients suffering from some complication which precludes crushing, are best dealt with by lithotripsy, followed immediately by external urethrotomy, in order to remove the whole stone at one sitting. 5. All calculi not exceeding one inch in the longer diameter ought to be crushed. 6. Phosphatic stones up to one inch and a half in the longer diameter may be crushed. 7. Lateral lithotripsy is specially indicated for the removal of calculi varying from one and a half inches to two and a half inches in their longer diameter. 8. Bilateral lithotomy is well adapted for the extraction of stones measuring from two and a half inches to three and a half inches in their shorter diameter. 9. The recto-vesical operation affords the most room for the removal of very large calculi, and is probably a safer method than supra-pubic lithotomy for such cases. 10. The median operation is only adapted for those cases in which lithotripsy has failed, and the immediate removal of the fragments is required. A similar remark applies also to the medio-lateral method. 11. Small stones in females may be best extracted by forcible dilatation. If large they had better be crushed, the female bladder and urethra being well adapted for performing lithotripsy.—*The Medical Press and Circular*, Jan. 8, 1879.

OSSEOUS UNION IN FRACTURE OF PATELLA.—Mr. Wheeler, of Dublin, reports an interesting case of fractured patella in which bony union is claimed to have taken place. Two years after the accident the patient died of phthisis, and Mr. Wheeler was fortunate enough to secure the specimen. This was submitted to Prof. Macalister for examination, who reported as follows: "I have macerated and examined the patella you sent me. Having cut it longitudinally, I find it to be bony throughout. The median half I have cleaned, and removed from its back the articular cartilage. It is a perfectly continuous bone, and shows a ridge of new bony matter across its articular face. The lateral half I have only slightly cleaned, but the union in it is very distinct and unmistakable. The sulcus at the upper and outer angle was filled by a mass of fibro-cartilage." This is one out of four cases which Mr. Wheeler has treated by his splint; the clinical results in the other three cases have been entirely satisfactory, and he feels confident of bony union in all. Mr. Butcher has used the splint three times, and confirms the advantages claimed for it. The apparatus consists of a box splint for securing the leg, which may be elevated or lowered at pleasure, and two metal plates, softly padded, secured, one above and one below the patella, by leathern straps. These plates are approximated by means of a chain and windlass, and maintain the fragments in perfect juxtaposition.—*The Medical Press and Circular*, Jan. 8, 1879.

FILARIE AND LEPROSY.—Mr. T. Spencer Cobbold reports a case of leprosy, related to him by Dr. Bancroft, of the Brisbane Hospital, in which filaræ were found in the blood. The patient was a native of England, had been in the colony twenty-five years, and had been in the habit of using well- and swamp-water. Dr. Bancroft adds that he has re-examined the blood of two patients who formerly had filaræ in connection with abscesses of the arm; their blood is now free from hamatozoa.—*The Lancet*, February 1.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 22, 1879.

THE PROPHYLAXIS OF SCARLET FEVER.

THE current medical literature of the past year or two shows a very marked increase in the attention that is being given to the prevention of scarlatina. It may be well to inquire whether amongst the many new drugs suggested, and new measures advised, there has been anything discovered of real value in providing immunity from this most destructive of the infectious diseases.

Scarlet fever is a purely contagious disease, but although this simplifies the question of prophylaxis, it does not make it an easy one; for the contagious principle has certain peculiarities which make it extremely difficult to discover whether, while making our most energetic attacks, we have really been influencing it at all. The contagion is not very volatile, it disseminates itself slowly, it has a most tenacious vitality, and it fastens itself only upon those persons who are predisposed to its influence, leaving others unharmed in spite of the fullest exposure. Thus, while its sluggish movements allow us time for various preventive measures, its vitality often sets these at naught, and its idiosyncrasies of attachment disturb all calculations in regard to prophylactic drugs.

Methods of prevention apply to communities and to the individual. In regard to the first, much has been done by various Boards of Health. These measures, however, after all cannot and do not prevent epidemics, but only lessen their extent. Scarlet fever is now endemic in all large cities, and its means of propagation are so numerous that even if once stamped out, no practicable quarantine could keep it away. All that can be done in this direction, therefore, is to make proper regulations concerning public schools and public conveyances, and to provide for proper quarantining and disinfection where cases have occurred. Such measures have been carried out in a number of cities and States. That they do not accomplish all that could be desired may be inferred

from the fact that we have had an extensive and severe epidemic in this city during the past winter. This has occurred in spite of sanitary regulations, and we can only have the satisfaction of knowing that it would surely have been worse without them.

Since State medicine, so far as we now know, can but partially affect scarlatina, in the way of prevention, attention is naturally turned to the discovery of such special drugs and measures as the individual physician can use for this purpose. And we here find a long list of preventive remedies, most of them recent, which have been urged with more or less confidence and enthusiasm upon the profession.

The very considerable success which attended the inoculations of small-pox led to a trial of a similar method with scarlatina. Some half-dozen reports of inoculations have been made, but only one experimenter has had favorable results, and the evidence on the whole goes to show that inoculation is not a justifiable measure.

The oldest of reputed prophylactics is belladonna. The fact that even now one occasionally meets reputable physicians who advocate its use testifies rather less after all to their scanty judgment than to the inscrutable ways of the scarlatinous poison. It will be found, however, that as a general thing confidence in belladonna is in inverse proportion to the extent of the physician's experience, and it is quite time now that we cease to paralyze the accommodation and impair the deglutition of patients on the unsubstantial ground that it will not do any harm and may do some good.

Since the popularity of the germ theory became established, children have been saturated with all kinds of anti-fermentatives, in the hope of preventing or curing the disease. Cases are reported where salicylic acid has apparently acted as a prophylactic. The hyposulphites have had the same indorsement. Carbolic acid has been much extolled. From two sources there have recently been strong recommendations of the sulpho-carbolate of soda. Acting upon a modified view of the germ theory, ozonic ether has been given internally and externally with great success, both in prevention and treatment. Upon nearly the same grounds chlorate of potash and vegetable acids are suggested as likely to be very efficacious. Strongly acid gargles, we have been assured, will kill the germ at the very threshold and prevent its infecting the system. Finally there has been advocated, on empirical grounds, a purely milk diet, and a series of cases to show its prophylactic value has been published.

We mention these various methods, chiefly because we believe that they only show how easily a drug may appear potent to an imagination that has been stimulated by alluring hypotheses. We confess to the greatest incredulity in regard to the efficacy of any of them. Indeed, the logic which leads to the adminis-

tration of any known anti-fermentative as a prophylactic has too unstable a ground to deserve much respect. In the first place, the question of what is the contagious principle of scarlatina has not yet got beyond the domain of probabilities. We can say, with much positiveness, to be sure, that it is no visible form of bacterium or micrococcus, and we can, perhaps, infer from analogy that it is a particulate something too small to be detected by the microscope, that it is albuminoid in composition and multiplies at the expense of physiological processes. Whether it is living or dead, whether it is the degenerated protoplasm of man or the modified protoplasm of vegetable, whether it acts in conjunction with bacteria or feeds directly upon the tissues, all these questions are much beyond the pathologist as yet. But, in any case, it is very hard to see how anti-fermentatives can reach this virus. If it is dead, we certainly need not give such drugs to kill it; if it is living, there is no evidence or probability that the system can be so saturated as to destroy such infecting protoplasm and not the living matter of the tissues at the same time. In the blood of persons deafened with quinine or salicylic acid the bacterium disports himself with as much activity as elsewhere, and the amœboid movement of the white blood-corpuscles can still be easily seen. It is a fact, to be sure, that there are drugs, like quinine, which affect the size and internal movements of the blood-globules, but we cannot infer from this that there are prophylactic germicides, which will not prove to be homicides at the same time. The idea then, we repeat, that anti-fermentatives will be efficacious, though not impossible, is inherently improbable, while the idiosyncrasy of the scarlet-fever poison will oblige observers to collect a vast number of cases in order to prove the prophylactic power of any particular drug. We do not wish to discourage experimentation, but it should be remembered that therapeutics are not advanced by continually announcing on the basis of a dozen cases new powers in drugs which further experience at once disproves.

Since there is then no internal medication on which we can rely to prevent the disease, we must turn to external methods; and, after all, much may be accomplished by these. Amongst them, complete isolation stands first, and is the only sure preventive. Next to this comes plenty of fresh air, and finally the disinfectants, of which heat and sulphurous acid are perhaps, at present, most popular. Carbolic acid, though once very much praised, does not seem to be so efficacious against this disease. There is very considerable evidence that greasing the body, perhaps with a disinfectant added, during the desquamative periods, together with warm baths, is of great value in preventing extension of the disease, since by this means so much of the infected epidermis is safely removed.

Particulars of this kind, however, are easily accessible, and we need not enter into them further. Al-

though we cannot yet root out endemic scarlet fever, nor avoid its epidemic occurrence, we can, at least, prevent its spreading through families and to many new localities, where formerly it could ravage at will.

CONCERNING PEDESTRIANISM.

THE results of the recent walking match are quite remarkable as showing the endurance of the human frame under prolonged and severe muscular exercise.

During the race the public has been treated to all the usual rates of progression, the long stride, the short step, the dog-trot, and the rapid run. It has been proved that short lower extremities are best for a long race, that an easy trot is more endurable than even a long walking stride, and that long legs are to be trusted only in comparatively short journeys. Bodies compactly built and even below the medium size have been shown to stand fatigue better than those of more commanding proportions and greater height. These facts bear somewhat upon the general laws relating to the vital force possessed by different individuals as calculated by the conformation of the body. Those who have made a study of anthropology have given the greatest vitality and the largest amount of endurance to the large-chested, long-bodied, under-sized persons.

Although every one is ready to applaud the achievements of men who perform their tasks so heroically, the conclusion is nevertheless irresistible that there is the greatest possible danger of straining their vital forces beyond repair. In fact, the latter condition seems a special danger in races upon which heavy sums are wagered, and upon which great sporting interests depend. From such a point of view, these performances prove only what can be endured in the shape of fatigue, and still allow the competitor to walk off the track.

The moral effect of this race will, doubtless, be to develop a mania for pedestrianism. If the latter is kept within the limits consistent with health, the recent excitement over the great match will not have been in vain. At all events, the standard prescription of the physician will probably not meet with as much opposition as formerly.

Aside from popularizing pedestrianism, the match has afforded an excellent opportunity for testing the theories of muscular force in their relations to food, animal heat, excretion, etc.

In the case of Weston many interesting and instructive facts were obtained, both here and in England. If any of the experiments were repeated during the recent contests, some important additional facts may be obtained, which may help to settle some doubtful points in nutrition and excretion. We have reason to believe, however, that in view of other interests which were considered paramount to scientific inquiry, no detailed or trustworthy observations were made.

NEW JOURNALS, AND "A WANT LONG FELT."

WHENEVER the projector of a new medical periodical says that he is to supply "a want long felt," we take the chances on his being mistaken. Not that any one who starts such a legitimate enterprise does not deserve success, but simply that he will not, as a rule, obtain it. This is a practical view of the question for which we have often been blamed, but really for no other cause than one would censure a physician for an unfavorable prognosis in any desperate case. It is true medical men should take every medical journal that is printed for them, but, unfortunately, they will not. The kind interest taken in their welfare by medical editors is not appreciated. This is the fault of the subscribers, of course, and not of the journals. We object to this disinterested spirit of benevolence on the part of new journals, and consequently protest against the casting of pearls before swine. The profession generally does not deserve to have any such want supplied, and should be made to suffer. One-sided benevolence, in the long run, is fatal to the enthusiasm of the benefactor, and the sooner the subscribers know it the better. We are impelled to make these remarks by way of introducing the following letter from our friend Dr. J. H. Pooley. The Ohio Medical Journal was well managed editorially, and was calculated to supply any real want felt there for a good journal, but, as Dr. Pooley informs us, a miscalculation was made. He very significantly says:

"The Ohio Medical and Surgical Journal has suspended. It was published to supply 'a want long felt,' but that want having been succeeded by another and more imperative one,—paying subscribers,—the journal ceases to exist. We request the friends of the journal not to aggravate our grief by letters of condolence or expressions of sympathy, but kindly leave us to suffer in silence."

Without wishing to intrude upon private grief we would simply suggest, by way of revenge on the profession in Columbus, that two new medical journals should be forced upon them in place of the one just deceased.

STATE BOARDS OF HEALTH.

THE receipt of the first annual report of the Illinois State Board of Health, and of the first annual address to the Connecticut State Board of Health is a reminder of the rapidity with which State medicine is being appreciated and introduced. Ten years ago there was hardly a country which possessed a well-organized system of public hygiene. Now, such systems exist in all the leading nations of Europe, and they are rapidly extending through our various States. In 1869 the first State Board of Health was established in Massachusetts. In 1877 such organizations had been formed in fifteen States. In all cases they have done good work, though often hampered by

lack of funds, and in some cases, as in Georgia, temporarily suspended by the exceeding thriftiness of the Legislature. The great value of State medicine, however, is steadily becoming recognized by thoughtful men, and Congress also is likely, in time, to be properly impressed with its importance.

In regard to particular boards, we think that that of Illinois deserves some special mention; for its establishment not only marked the extension of public hygiene westward, but its composition and function contain several novel features. The board is composed of representatives of the different schools of medicine. By law, every person who wishes to practise medicine in Illinois must obtain a license from this board, in order to do which he must either show a diploma from a medical college in good standing, or must pass an examination before the board. The statistics given in the first annual report both show that some law like this was needed and that it has acted very efficiently. There were 3,600 non-graduates practising in the State when the law went into effect; 1,400 of these have since left the State or quit practice; the rest have either secured diplomas, or passed the necessary examination, or have contrived to evade the law. Another result of this law is a great exodus of itinerant quacks, abortionists, etc., from the State. Such persons are obliged to pay one hundred dollars a month for the privilege of advertising themselves and their cures. According to the report of the board, the neighboring States are viewing with great interest and some alarm the effect of this purging of Illinois.

Reviews and Notices of Books.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA. Twenty-ninth Annual Session, held in Atlanta, Ga., April 17th, 18th, and 19th, 1878.

THE contents of this volume are, upon the whole, very creditable. The address of the president, Dr. WM. O'DANIEL, of Bullock, is of the usual type. Among other things, Dr. O'Daniel touches upon the difficulties encountered in obtaining prompt and sufficient remuneration for medical services from a certain class of well-to-do patients, who, it seems, are notoriously neglectful of their obligations in this respect. This he attributes mainly to "indiscretion, and a want of thorough organization in the profession," and advises that adequate compensation be exacted from those able to pay, and that when such compensation is refused or neglected, further services should be withheld; and would go still farther, and have these facts made known to the members of the profession interested, and that, after such notice, all those who continue to render services to such persons should be considered violators of ethical law, and be denied professional recognition.

The profession of Georgia are not alone in this particular, and it is to be hoped some plan can be found for remedying this evil, of which others outside of Georgia may likewise have the benefit.

Dr. O'Daniel cordially endorses the work done by

the State Board of Health, and urges the necessity of a committee to memorialize the next General Assembly for an increased appropriation and for sufficient powers to make the operation of the Board more efficient. He has not given the subject too much importance, and it is to be hoped that the committee appointed under the resolution of Dr. A. W. Griggs will have the desired effect.

The annual oration by the late Dr. Wm. R. BURGESS, of Macon, Ga., is a well written and characteristically conscientious paper. He dwells at length upon "Hasty, Unwise, and Unfortunate Medical Literature," discountenances crude theories and isolated cases, and warns the inexperienced physician from a too ready acceptance of many hasty and premature publications of the medical press.

Dr B. R. DOSTIN, of Early County, read a paper on "Amputation of the Leg for Necrosed Tibia of Thirty-four Years' Standing."

Dr. T. F. WALKER, of Cochran, reports a case of "Abnormal Conception," and one of "Eclampsia," and Dr. GEORGE J. GRIMES, of Columbus, remarks upon a case of "Tubercular Meningitis."

The paper of Dr. J. C. LE HONDY, of Savannah, is a most valuable contribution upon the subject of "Yellow Fever." He appends a tabulated statement in detail of one hundred and seventy-one cases of yellow fever treated by him in the epidemic which prevailed in the city of Savannah in 1876. It is well worthy of perusal by those interested in the subject.

The paper of Dr. JAMES B. BAIRD, of Atlanta, upon "Neuralgia and its Modern Therapeutics," is well written, and his conclusions, in the main, sound.

Dr. A. W. CAROUB, of Atlanta, gave a "Report of One Hundred and Thirty Operations for Strabismus" in his own practice, and concludes by saying that "the absence of all danger, and the great benefits to be gained by the operation, both in a cosmic and visual point of view, should induce every one affected with strabismus to submit to it without delay."

The "Report of the Section on Gynecology," by Dr. A. W. GRIGGS, the paper of Dr. S. H. STOUT, upon "Psoriasis Non-Syphilitica," and the considerations of Dr. T. S. POWELL upon "The True Physician," possess some interest.

The article, however, by Dr. V. H. TALIAFERRO, of Atlanta, upon "The Application of Pressure in Diseases of the Uterus," is extremely interesting, and should be read by every one. The wide range of utility which the principle advocated evidently possesses, and the simplicity of the method, are certainly strong recommendations in its favor. The use of sheep's wool instead of cotton wool for such purposes, is, no doubt, an improvement.

The "Pith of the Dried Cornstalk as a Uterine Tent" is the subject of Dr. W. T. GOLDSMITH's paper. He therein reviews the subject of uterine tents. Whether or not it possesses equal advantages with sponge, sea-tangle, or tupelo, as he claims, still remains to be tested; still it is likely to become a convenient material to many practitioners who live in remote parts of the country.

The different reports upon the sections on surgery, by Dr. A. A. Smith, from third district, and of Dr. Jno. Thad. Johnson, from fifth district, give opportunity for the consideration of cases of "Incised Wound of the Abdomen," "Hemorrhoids," "Perityphlitic Abscess," "Retention of Urine from an Unusual Form of Stricture," "The True Value of Caustics in the Treatment of Venereal Ulcers," "Gunshot Wound of the Head," "Adherent Prepuce," "Rupture of the

Uterus," and "Death from Cockle-Burr remaining in the Lung for Twelve Years."

A paper was contributed by Dr. Wm. A. LEONE, of Atlanta, upon the "Diagnostic Value of the Soft Palate, as compared with the Tongue in Certain Pathological Conditions."

Dr. C. B. LEITNER, of Columbus, calls attention to a new dressing for wounds in the form of a "Tar Bandage," and Dr. J. B. ROBERTS, of Sandusville, cites an "Obstinate Case of Hiccough."

These various articles comprise the medical subjects offered for consideration, and are certainly an earnest of much good work.

It is to be regretted, however, that so little discussion is usually had at these meetings upon medical subjects.

There is but one way to overcome the usual difficulties of want of time, etc., in this respect, and that is to divide into sections for the discussion of the various subjects, and then report in full session. It would be well for the Medical Association of Georgia in the future to adopt some such plan, thereby saving time and allowing a general expression of opinion; as it is, the papers are generally read by title, and are then referred to Committee on Publication.

The meeting seems to have been well attended and harmonious.

Compared with previous transactions, this one is an improvement. For the work done, congratulations are offered, and we wish the Association a profitable and pleasant meeting at its next session, which convenes April, 1879, at Rome, the home of Dr. Battey. The following is a list of officers for the present year: *President*, John Thad. Johnson; *Vice-Presidents*, Wm. F. Holh, Thomas H. Kenan; *Secretary*, Jas. B. Baird; *Treasurer*, Wm. R. Burgess; *Orator*, E. H. Richardson.

NEW AND ORIGINAL THEORIES OF THE GREAT PHYSICAL FORCES. By HENRY RAYMOND ROGERS, M.D. 12mo., pp. 107. Published by the Author. Trow's Printing and Bookbinding Co., New York, 1878.

This work is devoted to the exposition of a new philosophy, the key-note of which is contained in this extract from p. 19: "Let our philosophers but accept the idea that the sun rouses the earth into action through their mutual relationships; that the two interchange good offices and essential services, rather than that the sun is wholly independent, and simply gives outright, as philosophy has hitherto conceived, and we think the dawn of a better day has come." The author demonstrates his views clearly, and the argument stands in his favor. We recommend all who are interested in this problem to read this interesting and instructive book.

PROCEEDINGS OF KINGS COUNTY MEDICAL SOCIETY, Dec., 1878.

The most interesting paper in this volume was one in connection with the presentation of the fissured sternum of the late Dr. Groux. This fissure was two inches wide. It was not an arrest of osseous development but a central fissure, and looking through it within the chest a pulsating tumor, the heart, could be seen. Dr. Groux had the power of stopping the beating of his heart at will, it is said. The question of the possibility of this power was discussed. Both Dalton and Flint, Jr., deny that such power has been proved to exist. Dr. Groux, in some cases, at least, only stopped the pulse at the wrist. The very notable case of Col. Townshend occurred 150 years ago, and was only observed once. J. Milner Fothergill, however, asserts that there is an eminent English physiologist who has this power.

LECTURES ON LOCALIZATION IN DISEASES OF THE BRAIN, delivered at the Faculté de Médecine, Paris, 1875. By J. M. CHARCOT, edited by Bourneville, and translated by Edward P. Fowler, M.D., of New York. 8vo, pp. 133. Illustrations. New York: William Wood & Co., 1878.

THE LOCALIZATION OF CEREBRAL DISEASE, being the Gulstonian Lectures of the Royal College of Physicians for 1878. By DAVID FERRIER, M.D., F.R.S., etc. Demy 8vo, pp. 142, with illustrations. New York: G. P. Putnam's Sons, 1879.

THESE are two newly issued, small, but valuable books. The former will be welcomed in its English dress by the readers in this country, since anything from the pen or lips of M. Charcot is at once treasured by the profession. This author has labored so assiduously in the field of cerebral localization, both alone and in collaboration with M. Pitres and others, that he is in a position to speak *ex cathedra*. Our author exposes the anatomico-histological researches of Duret, Foville, Huguenin, Meynert, and others, as well as relates his own pathological observations, and those of others, bearing upon the subject under consideration. The subject matter is excellently arranged, and the text well illustrated by woodcuts. Dr. Fowler deserves our thanks for his very satisfactory and classical translation.

II. Ferrier's work is intended as a supplement to his "Functions of the Brain," wherein he detailed his experiments upon monkeys and other animals. The volume in hand deals in a well-arranged manner with the conclusions to be drawn from the author's experiments on animals as they relate to human physiology and pathology. Each special "centre" is described, mapped out, and illustrated by pathological cases and drawings. The views of Brown-Séquard, Saucerotte, Bouillaud, Hughlings-Jackson, and others are reviewed and criticised. While the author has clearly localized the various divisions of the "motor tract" as the result of his researches in comparative anatomy, he has drawn largely from the observations of Franck and Pitres, Charcot, and a host of others for his support from pathology. In comparing these two works we may say that M. Charcot's book is principally devoted to the study of the minute anatomy of the brain—the circulation, the course and relation of the fibres, cells, etc.—and to the physiology of the great cerebral centres. Nevertheless, the topography of the convolutions is not omitted. In Ferrier's book, however, we are treated to a complete exposition of the physiology of the "motor area," and to this alone. These books are the complement of each other. Possessed of both, the student of cerebral physiology will have the means at hand for a thorough understanding of "localizations," a difficult study.

IS PHTHISIS PULMONALIS CONTAGIOUS, AND DOES IT BELONG TO THE ZYMOTIC GROUP? By W. H. WEBB, M.D. Phila., 1878.

THE aim of this monograph is to prove that both the above questions should be answered in the affirmative. The author has spent much time and research in fortifying his position, which he sustains by clinical testimony and analogical reasoning. Nearly fifty prominent physicians are cited as inclining to the view that phthisis may be contagious. Many strongly illustrative cases are given, and such facts as the absence of phthisis from the South Sea Islanders and North American Indians, before their association with Europeans, are mentioned. Altogether the author makes out a very good case. We

believe it to be pretty clearly shown from clinical study and recent laboratory experiments that phthisis *may* be in a certain sense contagious. That it always is, however, or that it is a zymotic disease, can hardly be proved. But the fact of a possible contagiousness is an important one to bear in mind, and thanks are due Dr. Webb for so forcibly calling attention to the matter.

A PRACTICAL MANUAL OF THE DISEASES OF CHILDREN, with a Formulary. By EDWARD ELLIS, M.D., late Senior Physician to the Victoria Hospital for Sick Children; late Physician to the Samaritan Hospital for Women and Children; and formerly Obstetric Physician's Assistant to University College Hospital. Third edition. Pp. 213. New York: William Wood & Co., 1879.

DR. ELLIS's Manual on Diseases of Children has been issued by Messrs. William Wood & Co. as the second volume of their "Library of Standard Medical Authors." For a ready reference book it is not too much to say of it that we do not know of a book that has so much condensed in 213 pages, and yet not omitting anything essential, as the one under review. It makes no claim of being a systematic work, and therefore omits all controversial questions. Of course, in a work of this kind, there are some points which might have been more fully mentioned. This criticism we think is applicable to the notice of the diseases of the kidney, in which no mention is made of anything but "acute desquamative nephritis." About 40 pages are devoted to "general therapeutical hints and formulary." The volume has a very full index. It is printed on good paper, is well got up, and does credit to the publishers. We notice that the color of the binding comes off and is rather a blemish.

ELEMENTS OF COMPARATIVE ANATOMY. By CARL GEÖENBAUR, Professor of Anatomy, and Director of the Anatomical Institute at Heidelberg. Translated by F. Jeffrey Bell, B.A., and translation revised, etc., by E. RAY LANKESTER, M.A., F.R.S., etc. 8vo, pp. 624. London: Macmillan.

THE present volume, although a treatise in itself, is an abridgment of the author's larger volume, which has become so deservedly popular with students of anatomy. The general arrangement of the book is systematic and treats of the subject under the general heads of Protozoa, Coelenterata, Vermes, Echinoderma, Arthropoda, Brachiopoda, Mollusca, Tunicata, and Vertebrata. Each of these subdivisions are exhaustively treated in detail, and the salient points of differences clearly brought out. In fact, upon the latter method of treatment of the subject rests the real excellence of the work, and makes it a most desirable and valuable text-book for the student.

A MANUAL FOR THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., etc. Second American from third revised and enlarged English edition. 8vo, pp. 945. Philadelphia: H. C. Lea, 1879.

THE work before us is the American reprint of the last London edition, and has the advantage over the latter in being of more convenient size, and in being compressed into one volume. The author has rewritten the greater part of the work, and has succeeded, in the amount of new matter added, in making it markedly distinctive from previous editions. A few extra pages have been added, and also a few new illustrations introduced. The publishers have presented the work in a creditable style. As a concise and practical manual of British surgery it is perhaps without an equal, and will doubtless always be a favorite text-book with the student and practitioner.

Reports of Societies.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Feb. 24, 1879.

DR. A. E. M. PURDY, VICE-PRESIDENT, IN THE CHAIR.

PRIMARY ACUTE PURULENT INFLAMMATION OF THE MIDDLE EAR.

DR. H. KNAPP read an elaborate paper on the above subject, based on the statistics of 2,527 cases of ear disease seen private, and 6,102 cases seen in hospital practice. Among the former acute perforative otitis media occurred in 182, among the latter in 382 cases, that is, 6.53 per cent. of the whole number. He presented the statistics which he had collected of 27,359 ear patients treated at different institutions in America, and 6,562 patients treated in European institutions. The former showed the occurrence of perforative otitis med. in 6.08 per cent., the latter in 6.27 per cent. of the cases; almost the same proportion in both. Dr. Knapp had anticipated that the rapid changes of the American climate produced a greater number of cases of acute ear disease than the more equable climate of Europe.

As to the occurrence of acute purulent otit. med., he had prepared statistical tables, to show the relative frequency of the disease at the different ages of life and different months of the year.

Childhood (1st to 10th year) showed the greatest number, *i. e.*, 32.42 per cent. 62 per cent. of the cases occurred in the winter months; 38 per cent. in the summer months. In 85.71 per cent. of the cases only one ear was affected with perforative acute otitis; in 14.29 per cent. both ears.

ETIOLOGY.

The causes of the disease were given as follows:

Pharyngitis and rhino-pharyngitis	37.36	per cent.
Coryza	26.37	"
Sea-bathing	8.79	"
Scarlet fever	7.14	"

Then followed, with a smaller percentage, diphtheria, measles, pneumonia, improper use of the nasal douche, cold water and alcohol accidentally entering the ear, eczema of the auricle, mumps, and varioloid.

The dangers of sea-bathing were pointed out under two heads: local and general. Local, by the low temperature, the large quantity of salt, the impulse and contamination of sea-water. General, by the great cooling of the whole body, the cold and damp sea-air, and the dampness of the bed linen and covers. Several interesting cases of the disease, caused by diphtheria and the improper use of the nasal douche, were reported.

SYMPTOMATOLOGY.

Not entering into the whole symptomatology of the disease, Dr. Knapp presented detailed statements as to the beginning and duration of the otorrhœa and the termination of the disease. Concerning the latter, the following were the results obtained:

Perfect recovery with good hearing took place in	64.83	per cent. of the cases.
Discontinued treatment, when convalescent	7.69	p.c.
Transition in chronic aural catarrh	3.85	"
" " otorrhœa	4.39	"
Seen only once	17.03	"
Death	2.19	"

It followed that perfect recovery, at least in 80 per cent., was the rule in acute otit. med. pur. The fatal cases were reported in detail.

TREATMENT.

In speaking of the treatment, Dr. Knapp laid greater stress on the necessity of rest than was commonly done.

He thought that in acute inflammations of small organs, rest and care were just as essential to secure a complete recovery as in that of large organs, where rest was a matter of necessity, not of choice. The bad and lasting consequences resulting from imprudence and lack of care were convincingly dwelt upon.

The local treatment consisted in instillations of warm water into the ear; leeches around the ear; inflation of the drum, at first cautiously through the catheter, afterward according to Politzer's method; attention to the naso-pharyngeal cavity; astringent gargles; nebulizers; posterior nares syringe; steaming of the ear when the disease had suddenly ceased and the pain continued or increased; paracentesis of the drum; opening of the mastoid process; incisions down to the bone in the meatus and behind the ear, to liberate subperiosteal collections of pus; cleansing of the ear by syringing and wiping with a dentist's cottonholder; the use of astringent injections into the ear, which in the acute period should be avoided and afterward be suited in strength to the copiousness of the discharge and the proliferation of the mucous membrane. The indications, dangers, results, and the manner of application of the different modes of treatment, were duly dwelt upon. The paper will be published in *extenso* in the forthcoming number of the *Archives of Otolology*.

The paper being before the Society for discussion—

DR. D. B. ST. JOUX ROOSA remarked that he fully agreed with most of the conclusions reached by the author of the paper, and believed that that fact indicated there must be exactness in our knowledge upon this subject, because they were conclusions which had been reached by two men, who were working apart, and yet in the same department.

With reference to the question of statistics, there was a singular unanimity in those presented in Germany and in this country.

The proportion of acute suppuration of the middle ear, in one thousand cases, reported by Dr. Roosa, some years ago, was a little under three per cent. The proportion was increasing somewhat; and out of 3,173 ear cases occurring in his private practice, 102 were acute suppuration of the middle ear, one or both sides. The proportion was even greater than that; because he saw a considerable number of cases which were not recorded. Apart from statistics, he thought it was true that there was much more acute aural suppuration than either the speaker or himself knew about. For, many, if not all the cases of chronic aural catarrh, which were seen in such large numbers, were once acute cases. Besides that, earache occurred so commonly in childhood that many general practitioners never thought of reporting the fact; and nearly always those cases of earache were cases of acute aural catarrh, and often cases of acute aural suppuration. Among patients suffering from chronic aural catarrh it was a very common observation that they had been "getting deaf for several years, and finally thought it was time to see something about it," and in that way we obtained the knowledge that many cases of acute aural trouble were not seen by a physician. There were practitioners (they did not live in New York, he hoped) who absolutely ignored earache; and if they were to go into a house to prescribe for a case of

pneumonia or other disease, and were told that some member of the family was suffering from most intense pain in the ear, they would not listen to the story, much less prescribe for the case. Some of them would direct that the ear be wrapped up well with a poultice, and would tell the mother that "when the drum-head had broken Johnny would be better." But there was a great deal of acute aural disease which was recovered from very rapidly. To illustrate: he not long since saw a patient who first felt pain in the ear at about six o'clock, and at ten o'clock in the same evening the drum of the ear was very red; there was intense pain and other evidence of acute aural catarrh. A few applications of warm water from a tablespoon, without any other treatment, quieted all the symptoms. The patient slept well; and the next morning, upon examination, it was found that there was only a mere trace of redness of the membrane remaining.

With reference to the question of *rest*, he was not aware that any, who treated aural disease to any great extent, would doubt the correctness of the advice given by the author of the paper. What the author of the paper had said with regard to the *serious nature* of acute suppurative inflammation of the middle ear could not be overestimated.

With reference to paracentesis of the drum-membrane, in cases of acute catarrh of the middle ear, he thought the operation had very probably been overdone. There had been such a lethargy with reference to treatment of acute aural disease that it was necessary to insist upon operative interference in proper cases, and that had led to the opinion that otologists opened every drum-head which was reddened. But they did not do anything of the kind. The treatment of acute aural catarrh or acute aural suppuration was the simplest which could be imagined. If the ear was kept clean by the gentle use of warm water, the patient kept in bed, the pain subdued by the use of opium, and the bowels kept open, nothing, except an unwise interference, would prevent the drum-head from being restored, even when the disease had gone on to perforation.

He expressed his sympathy in the effort which the author of the paper had made to impress upon every one the importance of properly treating this important affection.

DR. C. R. AGNEW remarked that he agreed essentially with Dr. Knapp, and felt personally indebted to him for this admirable *résumé* of the subject. He did not think that Dr. Knapp would claim to start a new school of otology or to set forth views which were peculiar. They were those which were quite surely justified by the practice of all who treated diseases of the ear. We all appreciated the absolute necessity of rest, and practically that was secured because of the inability of the patient to locomote and pursue his ordinary avocation.

Dr. Agnew, however, was not quite so certain that his experience would lead him to the conclusion that rest in the supine posture was so valuable in these cases as Dr. Knapp's experience had led him to consider it to be. He had had the misfortune to have two attacks of acute inflammation of the middle ear, which, fortunately, resolved without perforation. He very well remembered the first attack, which came on about eleven o'clock at night, and the pain was so extremely severe that he found rest in the supine posture impossible, and he was obliged to rise from his bed and walk about the room. He took morphine freely, and while walking about the room, it asserted its hypnotic effect so strongly that he was obliged to

lie down; but as soon as he assumed the supine position the pain returned, and he was compelled to seek the upright posture. He had, therefore, recommended patients to sit rather than lie, and he thought the effect upon the circulation was favorable to resolution of the inflammation.

With reference to local depletion, he thought the same effect upon the inflammation might be obtained by applying a single leech just within the external auditory canal, as by applying several about the ear.

With reference to the use of warm water with a syringe or spoon, he agreed with the author of the paper and the speaker who had preceded him.

He thought it probable, if called in consultation with the same gentlemen, that he should agree with reference to the evidence which was to decide the question of paracentesis, but he did not think his experience justified the assertion that, when a drum-head was bulging, it was better to make a paracentesis than to wait until the lapse of one or two days in order to see whether discharge would not take place from the Eustachian tube. He thought, however, the possible damage which might be done to the mechanism of the middle ear by matter held in the drum-cavity was much greater than any possible injury which could come from paracentesis of the drum-head, provided syringing of the external auditory canal was avoided. He felt bound to say that he had never seen mischief done to the ear by paracentesis under circumstances which Dr. Knapp had described, when the drum-head was bulging and there was threatening perforation. The analogy between certain conditions of the eye, calling for puncture of the cornea, and certain conditions of the middle ear, calling for paracentesis of the drum-head, was a good one; but, like other parallels, it must not be pushed too far. He thought the paper by Dr. Knapp would put the subject of otology upon a better basis than it had heretofore occupied.

DR. PROUT directed attention to the effect produced in the ears by sea-bathing. He thought Dr. Knapp did not dwell sufficiently upon the passage of water into the middle ear through the Eustachian tube. He believed it occasionally happened that water entered the middle ear through the Eustachian tube, especially when the person swam upon the back.

He objected to the analogy between paracentesis of the cornea for hypopyon and paracentesis of the drum-membrane in acute suppurative inflammation of the middle ear. He favored paracentesis in cases of inflammation of the middle ear, rather than paracentesis of the cornea in cases of hypopyon. If there was not sufficient fluid to cause bulging of the drum-membrane, but simple redness, paracentesis should not be performed.

For local treatment he had found a useful combination to be laudanum, glycerine, and borax water, in acute external or middle ear trouble.

DR. SAMUEL SEXTON thought the operation of paracentesis was now carried too far. His attention had just been drawn to a report where the operation was performed forty-five times in an institution where only thirty-seven cases of acute purulent inflammation of the middle ear were reported, and he also found, on reviewing his own cases in the New York Ear Dispensary, he had operated on one-sixth of all such cases which were there treated. Saunders, the English surgeon, who was perhaps the first to recommend the operation, over seventy years ago, drew the line for operating when the accumulation of fluid in the tympanum partook of the nature of an abscess which threatened to burst, which was a good guide after all.

Dr. Sexton expressed his surprise that greater importance had not been given in the paper to the symptom of pain. When called to these cases, his first concern was to alleviate the anguishing pain which attended them, and to allay inflammation. In a great number of acute purulent inflammations of the middle ear there would be found to exist painful inflammations of the connective tissue in the neighborhood of the tympanum. In such cases suppuration was often averted or hastened to a conclusion by maturation, under the use of calcium sulphide, and, during its use, pain was in many instances greatly alleviated. As to the use of Politzer's air-douche in these cases, Dr. Sexton was not in the habit of resorting to it, as he saw no advantage to be gained by inflating the middle ear in acute cases; and reference having been made to the increase of the acuity of hearing during the period of inflammation, he would say that he regarded the temporary improvement of hearing as secondary in importance to the relief of pain and inflammation.

Dr. A. H. BUCK remarked that he had little more to say than to lay rather more stress upon the use of warm water in the beginning of acute ear trouble. He believed that early in the disease, especially in children, if the membrana tympani could be poulticed by pouring warm water into the ear with a spoon, in a great majority of cases the ear trouble could be arrested. Upon that practical point he would lay great stress. With reference to the question of paracentesis, he held the view expressed by Dr. Agnew. He believed that the harm which came from the operation, when properly performed, was small when compared with the harm which came from abstaining from its performance. The indications for the operation were so clear it seemed strange that any one should hesitate to resort to it, namely, bulging of the drum-membrane remaining after leeches, warm water, and simpler means had failed to afford relief. The pain was due to the pressure, and the incision relieved the pressure. He believed that the lack of success in the treatment of subacute and acute purulent inflammation of the middle ear was due largely to the fact that we had no more definite instructions relating to local treatment than the simple statement, use instillations of this, or that, or the other remedy. He thought the entire secret of success in treatment was found in adopting certain minute procedures. In the first place, the ear should be thoroughly cleansed, and then if instillations simply were used, the chances were that the remedy would not reach the membrane lining the middle ear, or at least reach it in very small quantities.

Dr. C. E. HACKLEY remarked, with reference to keeping the patient quiet, that it might seem almost impossible, but he thought those who had paid any special attention to diseases of the ear had frequently noted the difference between acute otitis media and boils occurring in the ear. Where the pain was as great in the one as in the other, the patient suffering from otitis media was inclined to keep quiet, whereas, if suffering from a boil in the ear, he was upon the constant move.

In the beginning of the disease he had seen as much relief follow snuffing warm water as from instillations into the ear. In children who could not adopt that method, he had observed decided benefit from the use of opium internally, in small doses.

With reference to etiology, he had learned, incidentally, that perforation of the drum of the ear was nearly as common in one lying-in asylum as was purulent ophthalmia in other institutions.

He believed that ear trouble following sea-bathing

was frequently caused by sea-water entering the middle ear through the Eustachian tube.

Dr. O. D. POMEROY remarked that he concurred in nearly all the statements which had been made, and added something in the way of personal experience with regard to relieving pain. He thought sufficient stress had not been laid upon measures for relieving that symptom. He had been accustomed to use warmth, perhaps more than others, and had employed dry rather than moist warmth. He was prejudiced against the use of moist warmth, because he had seen otorrhœa induced by its use. He referred to a case in which poultices had been faithfully employed in the treatment of acute otitis media, and, when they were removed, the pain soon ceased, and recovery followed without further treatment. Indian-meal, heated until browned and then put into a bag which could be fastened to the ear, was with him a favorite application. A hot brick wrapped in a napkin, or a bottle of hot water, was serviceable. For the relief of pain in the ear in small children, he had obtained good results from the use of a small quantity of black pepper wrapped in cotton and introduced into the ear; it relieved pain in a remarkable manner, and with that the inflammation.

He had been able, in his own case, to trace the attack up the Eustachian tube, and many times had been able, by applying a strong solution of nitrate of silver (60-80 grs. to the ℥ i.) to the throat, to relieve the pain and arrest the further progress of the disease.

Dr. E. GRUENING referred to opening the mastoid process in cases of otitis media. He had performed the operation seven times—five times in chronic cases, and twice in acute cases. He was confident that in the acute cases he saved the lives of the patients, and from those cases felt that the indications for the procedure could be formulated.

The first patient was a man thirty years of age, who had acute otitis media from bathing. Perforation of the drum-head occurred; but, in spite of that, the inflammation spread to the mastoid cells. The skin over the process became red, there was great pain, and the process was painful upon pressure. An incision was made, and for some hours the pain was relieved. The pain returned. The incision was enlarged, and it bled freely. High fever developed, there was severe pain in the head, the patient became delirious, and had a rigor. Dr. A. H. Buck was called in consultation, and it was decided to open the mastoid process. An abscess was found, a quantity of pus escaped, complete relief followed, and the man recovered.

In the second case the indications were the same, and the operation was performed with the same result. Dr. Gruening was surprised that none of the gentlemen had mentioned the operation, especially as Dr. Knapp had said that he was not in favor of it.

Dr. PINCKNEY alluded to the similarity between the symptoms in fatal cases of inflammation of the middle ear and the symptoms of typhoid fever, and thought there might be danger of mistaking one for the other.

Dr. F. A. CASTLE referred to the fact that in very small children there was a liability, because of the inability of the child to direct attention to the seat of pain, to overlook acute inflammation of the ear, and thus many cases were permitted to go on to suppuration and perforation of the drum-membrane.

Dr. KNAPP, in closing the discussion, subscribed to the suggestion made by Dr. Agnew, with reference to the erect posture. He dwelt upon rest in bed, be-

cause he regarded it as most favorable in reducing the action of the heart and breaking the force of the circulation.

With reference to opening the mastoid process, he had simply related his own experience; but certainly if pus was retained there, and it could be diagnosed as such, the operation should be performed. He thought the indications were not very frequent, since the exit of that pus into the middle ear would not be difficult. The operation became necessary chiefly when, in chronic cases, the mouth of the antrum became plugged with inspissated material.

With reference to applying a leech to the inner surface of the auditory canal, because a greater effect would be produced than by applying leeches about it, he thought that was true, but the objection which he had was that leech bites were sometimes followed by erysipelatous inflammation, and in that case the tissues became swollen, filled the canal and prevented the discharge from the ear from escaping readily.

With reference to the question by Dr. Prout concerning diagnosis, Dr. Knapp states that he had entered only such cases as really showed a discharge.

With regard to instillations reaching different portions of the drum cavity, he meant to state that, in the beginning of the disease, antiphlogistic treatment, by rest in bed, etc., was the principal feature, and that he preferred to treat the parts about the drum cavity rather than the drum cavity with remedies; resolution would take place in the natural decline of the inflammation. He had found in his experience that the use of caustics, and strong astringent solutions, in the first stage of acute inflammation of mucous membranes, was apt to aggravate the inflammation, even giving it a different character. Afterwards the rule was entirely different.

On motion made by Dr. Piffard, a vote of thanks was extended to Dr. Knapp for his valuable paper.

The Society then proceeded to the transaction of business.

DR. SAMUEL SEXTON was elected delegate to the State Medical Society, to fill the vacancy caused by the election of Dr. Horace P. Farnham as permanent member.

The Society then adjourned.

Correspondence.

THE POWER OF CARBOLIC ACID TO ABORT THE PUSTULATION OF SMALL-POX.

CHING-KIANG, CHINA, JAN. 30, 1879.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the "RECORD" No. 421, November 30th, it is stated on the authority of "*The Lancet*" that the efficacy of carbolic acid in aborting the eruption of variola is proved to be nothing; and secondly, that further investigation is required.

Of the value of the acid as an internal agent in the treatment of small-pox I am now unable to speak, but I have good reason to regard it as possessing power to abort pustulation if brought in direct contact with the eruption. For the past six years it has been my sole remedy in the treatment of small-pox, with the exception mayhap, of a night draught or a laxative—and during that period I have used it constantly in a somewhat extensive foreign and native practice. I

cannot better explain my method of treatment, than by an example from my case-book:

E. S., aged 34, merchant, has not been vaccinated since infancy; was taken ill at Shanghai, January 10th, twelve days after his visit to a man-of-war in this port of Ching-Kiang, on which small-pox had appeared some days before. Returned to his home on the third day after the disease had declared itself, and I saw him at midnight. Patient delirious; high fever; pulse 130; temperature 102°. He was at once placed in a large apartment with an open fire, the windows were opened, and venetians closed to exclude light. (The windows were not again closed during his illness, although snow fell, and the weather was unusually severe.)

January 14th.—The eruption has appeared, the face is much swollen, the eyes cannot be opened, there is a copious flow of saliva, and the patient is unconscious. Pulse 110; temperature 100°. Ordered to have face, neck, and arms frequently and freely anointed with a solution consisting of acid carbolic, ʒjss.; glycerine water, āā, ʒi., and to have the entire body sponged twice daily with a like solution.

January 16th.—Patient much better. Pustulation fully accomplished, and there is no delirium, and little fever. The pulse never again rose beyond 85, or the temperature above 99°. On the eighteenth day he visited me at my office, and while his face exhibited proof of how extensive had been the eruption, I was able to assure him there would be little sign left of his trouble, and so it proved, for I saw him after an interval of a year, and the pits on his face were limited to five.

I have not spoken of his secondary fever, because there was none, and it is a stage in small-pox I have long ceased to anticipate, regarding it as "dependent on absorption into the circulation of pus in a state of decomposition, or some product arising therefrom," which may be destroyed as formed, or even its formation prevented by an antagonistic agent, like carbolic acid. The application of a strong solution at first gives great pain, but very shortly is readily submitted to, even asked for, as it allays irritation, and the desire to scratch. Those pustules which are disposed to coalesce remain discrete, while those which are scattered fail to reach the size arrived at on such parts of the body, where, experimentally, the lotion is not applied. This at least has been my experience.

Yours faithfully,

A. R. PLATT, *Medical Officer.*

IMPERIAL MARITIME CUSTOMS, CHING-KIANG, CHINA.

Obituary.

JOHN M. WOODWORTH, M.D.,

SUPERVISING SURGEON-GENERAL, MARINE HOSPITAL SERVICE.

THE news of the death of Supervising Surgeon-General John M. Woodworth was wholly unexpected, save by those who were in attendance upon him during the last days of his illness. Within a week of his death he was seized with typhoid pneumonia, complicated with erysipelas, and being already much worn down by the arduous duties of his office, his remaining vital energies rapidly succumbed. Death occurred Friday, March 14th. Dr. Woodworth was born at Big Flats, Chemung Co., N. Y., Aug. 15, 1818. His parents soon after removed to Illinois, and at the War-

renville Seminary young Woodworth commenced his preliminary education, completing it at the University of Chicago. He next studied pharmacy, engaged in business, at the same time he commenced the study of medicine, graduating in 1862, in the Chicago Medical College. He then entered the army, first as Assistant Post Surgeon at Camp Douglas, and afterward in the field as Assistant Surgeon of volunteers. He was with Sherman's army from Corinth to the sea, being successively promoted to Surgeon, Medical Inspector of the Fifteenth Corps, and Medical Director of the Army of the Tennessee. He was complimented in general orders for his energy in the establishment of field hospitals during the Atlanta campaign, and again, in the subsequent campaign, for his moving ambulance hospital, which carried 100 wounded men from Atlanta to Savannah and placed them in hospital there without the loss of a single life, although a number of important operations had to be performed by the way. Brevetted Lieutenant-Colonel for distinguished services, three years after being mustered out of the service, he was appointed Post Surgeon of the Soldiers' Home at Chicago, and Sanitary Inspector of the Board of Health.

He then visited the hospitals of Berlin and Vienna, remaining abroad a year, and returning to Chicago, commenced the practice of his profession. The marine hospital service having been created in 1871, he became its chief officer, with the title of Supervising Surgeon-General. It is an act of ordinary justice to the deceased to say that the present efficiency of the service is due to his skilful system of organization and his remarkable executive ability. He discarded the system of appointing on political grounds, introduced competitive examination, and substituted the wholesome and inexpensive pavilion hospital for the heavy, costly, and badly-ventilated structures he found in use. Marine and hospital hygiene were his specialties; but as a naturalist he was scarcely the inferior of Prof. Baird, and as a histologist ranked as an expert, having passed the winters of 1859, 1860, and 1861 under the tutelage of the former in the Smithsonian Institution, and served as Professor of Histology for a year or more in the college at which he was graduated. His principal scientific works and papers are: the "Mystery of Life," published in 1871; "Regulations of the United States Hospital Marine Service," 1873; "Hospitals and Hospital Construction," 1873; "Cholera in 1873 in the United States;" "Migrants and Sailors in their Relation to Public Health;" "Safety of Ships and those who Travel in Them," and "Quarantine with Reference to Yellow Fever." His work on the "Nomenclature of Diseases," 1874, is the standard reference of the marine hospital service.

Largely through his instrumentality the National Quarantine Act became an accomplished fact, and by his prompt and skilful interpretation of its provisions he achieved a national reputation. During the late yellow fever epidemic he devoted himself to the sufferers and succeeded in establishing a commission of inquiry, which was afterwards merged into that of the Commission of Experts, of which he was appointed by Congress as president *ex-officio*. With the work done by this commission our readers are already sufficiently familiar. During the past few months Dr. Woodworth devoted himself to the procuring of legislation bearing upon the creation of a National Health Bureau. His untimely death will be greatly regretted by the medical profession, and by that large class of persons whom he was the means of befriending in their dire calamities.

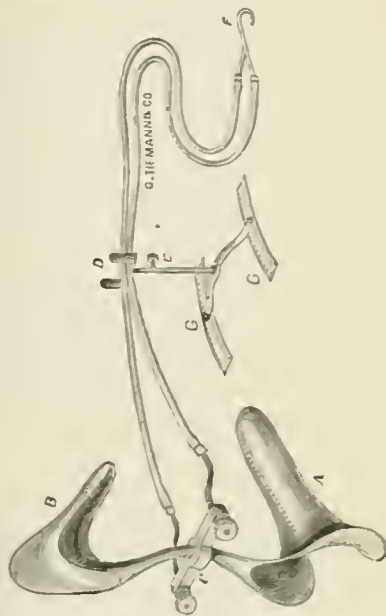

New Instruments.

AN ADDITION TO THE SIMS'S SPECULUM FOR MAKING THAT INSTRUMENT SELF-RETAINING.

By B. E. FRYER, M.D.,

SURGEON U. S. ARMY.

WE have devised a very simple addition, which can be made to any Sims's Speculum, and which readily allows of that instrument being used as a self-retaining one. The accompanying wood-cut illustrates the speculum with this addition applied to it.

A and B are the blades of the instrument; at C two parallel bars, running at right angles to the shaft of the speculum, are clamped firmly by circular milled nuts, which turn upon two cylindrical bars, which latter, at their further extremity, are slightly curved. Upon each of the ends of the curved bars is fastened a piece of India-rubber tubing, and the tubing is united in a metal hook at F. At D, the tubes pass over what we call the "bridge," which has a base at C. The vertical portion of the bridge allows of being raised or lowered, and of retention at the desired height by a screw at E.

The flange of the blades, or specular portion of the instrument, is modelled after that of Emmet, and these blades are so bent as to make with the handle or shaft an angle less than that in the Sims's instrument as usually made; this lessened angle, as is now generally known, having been found a more convenient one.

The mode of using the instrument is quite simple. The cross-bars being loosened by turning the milled nuts, are slid up the handle out of the way, the blade to be used is introduced (the patient being of course in the Sims's position) the cross-bars are brought down again, as shown in the woodcut and fastened; the bridge is placed on the patient's sacrum, over the clothes, and the rubber tube carried over the patient's right shoulder. The operator now draws upon the

speculum, as is done in the Sims's instrument until sufficient perineal retraction is had, when the tubes, which have been carried over the patient's right shoulder, are drawn upon by the patient (or assistant), and either held in her right hand or are fastened by the hook to a staple in the table on which she is lying. It will be found that a very slight strain by the patient will retain the instrument, for the tubes bind, as it were, upon the shoulder, and allow of the retention of the instrument by a but comparatively slight muscular effort; and even if this effort is impossible, as it would of course in a prolonged operation, and in any case under anaesthesia, the hook could be easily fastened so as to hold the instrument firmly. The elasticity of the rubber tubes, it will be found, equalizes the tension admirably.

Of course it is understood that for the specialist, practising in a large city and with well trained assistants and a good nurse always at command, a self-retaining instrument is not essential, but for the general practitioner, who is frequently prevented from using the Sims's instrument, which is the best of all specula, simply from the difficulty in obtaining such aid, it is believed that a satisfactory self-retaining instrument will be very advantageous and desirable.

The instrument is made by Messrs. G. Tiemann & Co., New York.

In drawing the illustration of the instrument, the draughtsman has made a slight error, which however is unimportant and which will be readily understood. The curved bars, to which are attached the rubber tubes, should be turned a half circle, if the blade A is being used, which in the engraving it is represented as. The illustration shows the bars in proper position for the use of the blade B.

FORT LEAVENWORTH, KANSAS, February, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 9 to March 15, 1879.

TOWN, F. L., Major and Surgeon. To accompany the first detachment of recruits to the Pacific Coast, and upon completion of this duty report in person to the Commanding General, Department of the Columbia, for assignment to duty. S. O. 58, A. G. O., March 11, 1879.

TILTON, H. R., Major and Surgeon. To report to Commanding General, Department of the Missouri, for assignment to duty. S. O. 58, C. S., A. G. O.

DEWITT, C., Capt. and Asst.-Surgeon. To proceed to New York City, report in person to the President of the Army Medical Board for examination, for promotion, and upon completion of examination rejoin his proper station. S. O. 58, C. S., A. G. O.

LAUDERDALE, J. V., Capt. and Asst.-Surgeon. Assigned to duty at Mt. Vernon Barracks, Ala. S. O. 40, Department of the South, March 6, 1879.

DELOFFRE, A. A., First Lieut. and Asst.-Surgeon. To report in person to the Commanding General, Department of the South, for assignment to duty. S. O. 58, C. S., A. G. O.

PORTER, J. Y., First Lieutenant and Asst.-Surgeon. Granted leave of absence for one month, from 1st proximo. S. O. 41, Department of the South, March 7, 1879.

POWELL, J. L., First Lieut. and Asst.-Surgeon (recently appointed). To report in person to the Commanding General, Department of Texas, for assignment to duty. S. O. 58, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of Contagious Diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending March 15, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Mar. 8, 1879.	0	4	198	2	1	52	0	0
Mar. 15, 1879.	0	7	215	1	17	39	0	0

VITAL STATISTICS OF NEW YORK FOR 1878.—The Health Department of the City of New York furnish the following statistics:

Population of the City of New York, according to the New York State Census, estimated July 1, 1878, was 1,083,371; total births (not including still-births), 25,729; total marriages, 7,629; total still-births, 2,192; total deaths (not including still-births), 27,008; total deaths of children under 5 years of age, 12,410.

Percentage to the total mortality.—Deaths of children under 5 years of age, 45.95; deaths of persons 5 years of age and over, 54.05.

Number of deaths from—Small-pox, 2; measles, 272; scarlatina, 1,099; diphtheria, 1,007; croup, 499; whooping-cough, 382; typhus fever, 4; typhoid fever, 245; cerebro-spinal fever, 97; phthisis pulmonalis, 4,466; pneumonia, 2,288; bronchitis, 1,184.

Diarrhoeal diseases.—Children under 5 years of age, 2,598; all ages, 2,945.

Death-rate per 1,000 inhabitants, 24.93.

Meteorology.—Mean temperature (Fahr.), 53.52; mean pressure (barometric inches), 29.850; mean humidity (saturation 100), .74; number of miles travelled by the wind, 54,988; total rain-fall (in inches), 48.66.

TENIA MEOICANELLATA.—At a recent meeting of the Philadelphia Academy of Natural Sciences, Prof. Leidy exhibited two specimens of tapeworms, *Tenia Meoicanellata*, both retaining the head. These had been recently submitted to him for examination by Dr. James J. Levick and Dr. Walter F. Atlee. Tapeworm appears not to be a common affection with us. Several physicians, in extensive practice in Philadelphia, had informed him that they never had a case. During the last ten or fifteen years from one to two specimens annually had been submitted to him, but the present year he had seen five specimens. He had been surprised to find that all pertained to the species indicated. Formerly he supposed that our common species was the *Tenia solium*, but later experience would indicate that the *Tenia meoicanellata* is the more common. The distinction between the two had been observed only comparatively recently, so that no doubt many specimens formerly attributed to the former actually belonged to the latter.

When the head is present the two species are readily distinguished. The *Tenia solium*, whose larval form is found in the "measle" of pork, has the head provided with a crown of hooks. *Tenia meoicanellata*, derived from beef and mutton, has a larger head, which is unarmed. The ripe segments are also usually readily distinguished in the two species. In the *Tenia meoicanellata* the ovaries are divided into many more pouches than in *Tenia solium*.

In Dr. Levick's case the man had been in the habit of eating raw buffalo meat. In one of the specimens exhibited, the suckers of the head appeared as black spots, from the black pigment on their interior surface. The genital apertures were also black from the same cause. In the other specimen the head appeared less black from pigment about and around the position of the suckers, and the genital apertures do not appear black.

THE PHILADELPHIA WOMAN'S MEDICAL COLLEGE COMMENCEMENT.—The annual commencement was held in Association Hall, Philadelphia, on March 13th. The exercises were opened with a prayer by the Rev. Dr. D. O. Kellogg. T. Morris Perot, Esq., President of the Board of Corporators, conferred degrees upon twenty graduates. The degree of M.D. was also conferred upon Rachel L. Bodley, A.M., the Dean of the College. The valedictory address was delivered by Prof. Clara Marshall, M.D. The prize of \$50 for the best report of the lectures during the past term was awarded equally to Anna S. Kugler and Louisa Schneider, both of Pennsylvania.

THE COMMENCEMENT OF THE MEDICAL SCHOOL OF THE UNIVERSITY OF PENNSYLVANIA.—The Alumni Association of the Medical Department of the University of Pennsylvania held its annual meeting on Thursday evening, March 13th. The oration was delivered by Dr. Steiner, of Maryland. The following officers were elected: President, Geo. B. Wood; Vice-Presidents, John L. Atlee, Meredith Clymer, W. S. W. Ruschenberger, and T. J. Gallagher; Treasurer, Wharton Sinkler; Executive Committee, Hiram Corson, Ed. Hartshorne, Wm. Hunt, Andrew Nebinger, John H. Packard, H. Lenox Hodge, James H. Hutchinson, James Tyson, Wm. F. Norris, Samuel Ashhurst, Thomas J. Yarrow, R. A. Cleemann, Wm. Pepper, S. S. Stryker, C. B. Nancrede, DeF. Willard, Louis Starr, Charles Baum, Charles M. Seltzer, and Thomas H. Cathcart; Corresponding Secretary, H. R. Wharton. The orator for 1880 is Traill Green, of Easton, Pa.

The annual commencement of the Medical Department of the University of Pennsylvania took place on Friday, March 14th, at the Philadelphia Academy of Music. The exercises were opened with prayer by the Rev. Samuel E. Appleton, D.D., after which Provost Stillé conferred the degree of M.D. upon ninety-one graduates, and that of D.D.S. upon twenty-five graduates. The first prize of \$100 for the best essay was awarded to Wm. G. Davis, of Pennsylvania, and the second prize of \$100 was divided between F. H. Cathcart and D. Cerna, of Pennsylvania. Those who were mentioned as distinguished were G. E. Abbot, Ph.D., Wm. H. Burk, and Wm. E. Casselberry, Pennsylvania; J. M. Frazier, Texas; Peter McGough, Pennsylvania; E. T. Reichert, Pennsylvania, and J. S. Stone, W. Virginia. The gold medal anatomical prize was awarded to Frank O. Nagle, of Pennsylvania, and the prize for the best list of anatomical anomalies found in the dissecting room to L. P. Carbonell, Cuba. The valedictory address was spoken by Prof. John Ashhurst, Jr.

PREGNANCY IN THE ELEPHANT.—At the invitation of Mr. Tule, the manager of the "Great London Circus," a number of medical gentlemen, among whom were Professors Joseph Leidy, R. A. F. Penrose, and Harrison Allen, of the University of Pennsylvania, and Drs. Henry C. Chapman, John H. Brinton, and Frank F. Maury, visited the winter quarters of the circus at Twenty-third Street and Columbia Avenue, in Philadelphia, on Friday, March 14th, in

order to inspect a female elephant said to be pregnant.

During the course of the examination some points of great interest to the medical and scientific world were brought out.

The female elephant believed to be pregnant had been covered twice by a male elephant at Concord, New Hampshire, on the 25th of May, 1878. At the time of examination she was consequently in the tenth month of pregnancy.

The two breasts, which are situated immediately between the front legs in the elephant, were full and swollen. The nipples were very prominent, and pointed outwards and downwards instead of directly downwards. The milk veins on the surface of the abdomen were also very prominent.

The general opinion hitherto held with regard to the act of copulation on the part of the elephant has been that it is performed while the female lies on her back. This is the view taken in all works on the subject. Additional reasonableness was no doubt lent to this view by the fact that the penis of the male elephant when artificially caused to be erected by titillation of the rudimentary mammary glands points downwards and backwards, the glands curving inwards upon itself, and not forwards and upwards as in the human species, and that this state of affairs seemed to be demanded by the position of the urethra in the female, the opening of which lies well between the hind legs, and the calibre of which points almost directly upwards towards the rectum.

In this instance, however, the act of copulation had been twice performed, and on both occasions the male had mounted upon the back of the female, and the penis, instead of curving backwards as is the case under artificial sexual excitement, had *curved forwards and upwards*. These facts were very thoroughly authenticated. This proves that previous ideas upon this subject have been altogether erroneous.

The fact was shown, to the great wonder of those present, that the elephant's height is always equal to twice the circumference of the soles of its feet, the natives in India employing this means of determining the height of a captured elephant.

Curious glands, sebaceous in origin, were pointed out by the keeper in the roof of the elephant's mouth and behind the eyes. In the glands behind the eyes wax is wont to accumulate, and causes much annoyance to the elephant unless removed.

It was further shown that the tongue of the elephant does not possess any frenum.

As the period of normal pregnancy in the elephant is twenty months, it was expected that the calf would be born, if nothing unforeseen should occur, on January 25th, 1880. The birth of an elephant calf away from India is a great rarity.

TRANSACTIONS OF THE KENTUCKY STATE MEDICAL SOCIETY, Frankfort, Ky., April, 1878.—Besides the regular contributions on medical subjects, several memorial addresses were delivered on the late Dr. L. P. Yandell. Dr. Charles H. Todd, of Owensboro, was elected *President*, and Dr. L. S. McMurtry, of Danville, *Secretary* for the ensuing year.

RUSH MEDICAL COLLEGE.—Dr. James Nevins Hyde has been made a professor of "Dermatology and Venereal Diseases" in Rush College; and Dr. John E. Owens has received the appointment of professor of "Orthopedic Surgery" in the same institution. Both Chairs are now, for the first time, established in the regular course of this college.

JEFFERSON MEDICAL COLLEGE COMMENCEMENT.—At the annual meeting of the Alumni Association of Jefferson Medical College, held on Tuesday afternoon, March 11th, the following officers were elected: President, Sam'l D. Gross, M.D., LL.D. Vice Presidents, Addinell Hewson, M.D.; Edward Caswell, M.D.; Elwood Wilson, M.D.; and P. S. Connor, M.D. Treasurer, Nathan Hatfield, M.D. Recording Secretary, Thomas H. Andrews. Corresponding Secretary, Richard J. Dunglison. The Annual Address before the Alumni Association was delivered on Tuesday evening, March 11th, in the lecture room of the college hospital, by Dr. Edward T. Caswell, of Providence, R. I., in the presence of a large audience. The subject of the address was "The Present Phase of the Alcohol Question from a Medical Point of View."

The Fifty-fourth Annual Commencement of Jefferson Medical College was held in the Philadelphia Academy of Music, on Wednesday morning, March 12th. The Rev. Thomas F. Davies opened the exercises with a prayer, after which Dr. Gardette, the President of the Board of Trustees, conferred degrees upon *one hundred and ninety-six graduates*.

The following prizes were awarded by the Dean:—A prize of \$100, by Henry C. Lea, Esq., for the best thesis, to Henry C. Boenning, of Penn., with honorable mention of the theses of Frank E. Stewart, of New York; Wm. L. Kneedler, of Pa.; Carlos M. Brown, of Cal.; Monroe Bond, of New Hampshire, and Wm. S. Hoy, of West Va. A prize of \$50 for the best essay on a subject pertaining to surgery, to Bernard R. Lee, of Pa., with honorable mention of the theses of Norman H. Chapman, of Illinois, and Henry Ness, of Pa. A prize of \$50 for the best anatomical preparation, to Wm. L. Kneedler, of Pa. A prize of \$50 for the best essay on a subject pertaining to obstetrics, etc., to David C. Lichtler, of Va., with honorable mention of the theses of Howard F. Hansell, of Pa. A prize of \$50 for the best essay on a subject pertaining to Materia Medica and Therapeutics, to Louis Weiss, of Colorado, with honorable mention of the thesis of Albert T. Poffenberger, of Pa. A prize of \$50 for the best essay on a subject pertaining to Physiology, to Wm. C. Caball, of Del. A prize of \$50 for the best essay on a subject pertaining to the theory and practice of medicine, to Jno. L. Yard, of Pa., with honorable mention of the thesis of Wm. L. Rodman, of Kentucky. A prize of \$50 for the best essay on a subject pertaining to chemistry, to Geo. W. Cram, of Pa., with honorable mention of the thesis of James R. Duggan, of Georgia. A prize of a gold medal, by the demonstrator of surgery, for excellence in bandaging, to Lawrence F. Flicke, of Pa., with honorable mention of G. A. Scroggs, of Ohio. A prize of a gold medal, by R. J. Levis, M.D., for the best report of his surgical clinic at the Pennsylvania Hospital, to Chas. M. Gandy, of N. J., with honorable mention of Norman H. Chapman, of Ill., Addinell Hewson, Jr., of Philadelphia, and Bernard R. Lee and Wm. H. Righter, of Pa.

After the delivery of the class valedictory by Geo. T. McCord, the valedictory address was read by Dr. James Aitken Meigs, Professor of the Institutes of Medicine and of Medical Jurisprudence. This address was a novelty of its kind, being entirely in verse of classic metre.

THE PHILADELPHIA DENTAL COLLEGE COMMENCEMENTS.—The Pennsylvania College of Dental Surgery held its Commencement at the Academy of Music, in that city, on Friday evening, February 28th. There

were 42 graduates. Prof. J. Ewing Mears, M.D., delivered the valedictory address.

The Philadelphia Dental College held its annual Commencement at the same place on Thursday evening, February 27th. There were 49 graduates. Prof. Sam'l B. Howell, M.D., delivered the valedictory.

The meeting of the Alumni Association of the Philadelphia Dental College was held in the college building, on Friday morning, Feb. 28th, when papers were read by Drs. T. C. Stellwagon, of Phila.; C. E. Francis, of N. Y.; L. Ashley Faight, of Pa.; F. L. Bassett, of N. J.; A. N. Roussel, of Pa.; and Prof. Royce.

IPECACUANHA AS A RELIABLE AND POTENT OXYTOIC.—Dr. J. H. Carriger, of Knoxville, Tenn., claims that *Ipecacuanha* is a reliable and potent oxytocic, safer than ergot, and that it facilitates the dilatation of the rigid os. Two grains was the usual dose; prompt effects followed.—*New York Med. Jour.*, Nov., 1878.

PROF. ALFRED STILLÉ, of the University of Penn. Medical School, in accordance with a determination expressed by him to serve but fifteen years, when he was elected in 1863 to the chair of the Theory and Practice of Medicine, lately handed in his resignation. At the special request of the Trustees, however, the doctor was persuaded to withdraw the resignation.

PROF. WM. H. BYFORD, who has occupied the chair of Obstetrics and Diseases of Women in the Chicago Medical College since its organization, twenty years ago, has resigned to accept the chair of Gynecology in Rush College. Prof. Dr. Laskie Miller retains the chair of Obstetrics in Rush College.

WALLACE'S CRANIOCLAST.—Prof. Ellerslie Wallace, of Jefferson Medical College, exhibited to his class, upon a recent occasion, a new and valuable cranio-clast, devised by himself, and made by Mr. Gemrig, of Philadelphia. The blades are of the Hodge shape, but hollow and unfenestrated. The peculiar value of the instrument depends upon an ingenious mechanism, by means of which two long teeth are sprung in the hollow of each blade so soon as the instrument has first been placed in position, claspings the foetal head, and has then been slightly relaxed so as to allow these teeth room to act. Dr. Wallace recently, in consultation, delivered a child, first crushing its head, when all other instruments had utterly failed. The instrument will not release its hold until either the woman has been completely delivered, or the head of the child has been torn from its body. The price of the instrument is \$50.

WOMAN'S HOSPITAL, STATE OF ILLINOIS.—There has been difficulty of late in the management of the Woman's Hospital of the State of Illinois, between the board of lady managers and Dr. Jackson, the surgeon-in-chief. As a result, Dr. J. has resigned with the rest of the medical staff. A new staff has been called to the institution, at the head of which is Prof. Byford. The other members are Drs. Rolan, Merriman, Nelson, Sawyer, and Flood.

A LOCAL ANÆSTHETIC.—R. Pulv. camph., 3 vi.; æther. sulph., f. ̄i. M. Apply to the gum surrounding the tooth to be removed until the gum turns white, when the tooth can be extracted with scarcely any pain.—*Dental Cosmos*.

PHOSPHIDE OF ZINC IN HYPOCHONDRIA.—On the ground of three observations, Trubert recommends the phosphide of zinc in hypochondria, in the daily dose of 12 milligrammes (gr. 1½). He has also found this remedy to be more efficacious than any other in the treatment of hysteria.—*Der Irrenfreund*.

Original Communications.

ON SOME OF THE SURGICAL USES OF THE ACTUAL CAUTERY.

By ALFRED C. POST, M.D., LL.D.,

VISITING SURGEON TO THE PRESBYTERIAN HOSPITAL, IN THE CITY OF NEW YORK.

(Read before the Medical Society of the State of New York, Feb. 6, 1879.)

THERE is an old adage, "Quod medicamenta non sanant sanat ferrum: quod ferrum non sanat, sanat ignis."

There is no doubt that the actual cautery has often been misapplied, and that its use has been blindly resorted to by persons who have been ignorant of the true pathological conditions of the diseases in which it has been employed, and of the exact therapeutical indications for their treatment. Thus I have heard of a quack who, when called to treat an obstinate ulcer, covered its surface with inflammable materials, which he set on fire, saying that he did not know how to cure the sore, but he did know how to cure a burn.

But I am well satisfied that, in appropriate cases, and with proper precautions, the actual cautery is a remedy of great value, as a means of relieving severe and protracted suffering, of arresting the progress of disease, of preventing extensive disorganization of important parts, and of averting fatal results of morbid action.

At an early period of my professional life, during a temporary residence in Germany, my attention was drawn to the value of this important remedy by a pamphlet published by Ritter von Kern, of Vienna, entitled "Ueber die Anwendung des Glüheisens in der Verhandlung der Gelenkkrankheiten."

Soon after my return to this country I began to employ the remedy in the treatment of chronic diseases of the joints, and to direct the attention of other surgeons to its value as a therapeutical measure in this class of cases. And I have not been disappointed in my expectation of the valuable results to be obtained from this mode of treatment. And having had such ample proof of its beneficial effects in diseases of the articulations, I have been led by analogy to apply the same remedy in other diseases characterized by obstinate, severe, and disorganizing inflammation, or by severe and protracted pain, not yielding to other treatment. I propose, on the present occasion, to lay before the Society some of the results of my experience, and to indicate some of the directions in which further observations may advantageously be made.

The term actual cautery may include any form in which heat may be applied to the surface of the body so as to produce a greater or less degree of irritation of the part to which it is applied, and a greater or less degree of disorganization of the tissues which are immediately involved. The agent may be a bundle of solar rays, concentrated by a lens, a metallic or other body of strong conducting power, heated by fire or by an electric current, a flame directed upon the surface by means of a blow-pipe, or a combustible body ignited in contact with the surface.

The action of the heat may be so gentle as simply to redden the surface, or it may occasion vesication, or it may disorganize the skin throughout a part or the whole of its thickness, or the deeper tissues may be involved in the same disorganizing process. The different forms of the actual cautery, and the different

degrees of their action, are applicable to the treatment of a variety of morbid conditions.

I will here enumerate some of the principal therapeutical uses of the actual cautery in its different forms:

I.—It is employed as a hemostatic. This was one of its earliest applications. And before the introduction of the ligature as a means of arresting arterial hemorrhage the cautery was much more extensively used for this purpose than it is at the present time. But there are many cases in which the ligature cannot be applied without deep and extensive incisions in the midst of important parts, where the actual cautery may be used as a substitute with great advantage. And there are other situations, as in the fauces, the vagina, and the rectum, where the ligature cannot be applied, and where the actual cautery is our principal reliance for the arrest of hemorrhage. There are certain precautions which are necessary to be observed in order that we may obtain the best results from the employment of the cautery as a hemostatic.

1st. The hemorrhage should be temporarily arrested, if possible, at the moment when the cautery is applied. If the seat of the hemorrhage be in one of the extremities this object is best accomplished by the application of Esmarch's elastic bandage. In other situations pressure may be made by means of a sponge, squeezed as dry as possible, and withdrawn at the moment when the cautery is to be applied. The application of the cautery in the midst of a puddle of blood is, of course, a very unreliable remedy.

2d. The cautery should be heated only to a dull red heat, and the application to the bleeding surface should not be prolonged. If the cautery be at a white heat it destroys the coats of the vessels more rapidly than it coagulates the blood, and may thus increase the hemorrhage instead of arresting it. The same effect may be produced by a cautery at a red heat if the pressure be too great, or if it be continued too long a time. If the cautery be at a black heat it may be applied more firmly, and it may be kept a longer time in contact with the tissues.

In selecting a cautery to be used as a hemostatic we may be governed, in some measure, by the condition of the part to which it is to be applied. We may use for this purpose the old cauterizing iron, heated by a charcoal fire, by a Bunsen's burner, or by a spirit blow-pipe, or we may have recourse to the galvanic cautery or to the benzine cautery. The simple and inexpensive cauterizing iron may be used with entire satisfaction in most regions of the body. But in the fauces, and in the deeper parts of the vagina or of the rectum there is an advantage in the use of the galvanic or the benzine cautery, as either of these instruments may be used with more deliberation and with more precision.

II.—The actual cautery is employed in the treatment of vascular tumors, with the intention of constricting the vessels, of coagulating the blood, and of exciting plastic exudation, by which the whole of the affected tissue is solidified, and its vascularity diminished. For this purpose the cautery may be used in a variety of forms. In the treatment of superficial telangiectases, involving the arterial capillaries of the skin, the solar rays, concentrated to a focus upon the vascular surface by means of a lens, will accomplish the object speedily, without any breach of the surface, and without the formation of a scar to disfigure the patient. This method was introduced by Mr. Augustus Barnes, and an account of it published in the *Medical and Surgical Reporter* by Dr. Pineknay W. Ellsworth, of Hartford, Conn., and quoted in the *MEDICAL REC-*

ORD of Dec. 15, 1866. (The same class of morbid growths may be treated by the flame of a blow-pipe cautiously directed upon the surface. But the more common mode of applying the actual cautery in the treatment of telangiectasis is by the use of cauterizing needles, which are made to penetrate the interior of the diseased tissue. The needles should be blunt at the point, as, if they penetrate the tissue mechanically, they will give rise to troublesome hemorrhage. They should be heated to a dull red heat, and should be applied at a great number of points, that the influence of their application may be extended to the whole of the morbid growth.

A very convenient instrument for this purpose is the multiple cautery devised by Dr. Thorp, of Chango Co., in this State. It consists of six metallic wires set in a frame, at a distance of a sixteenth to an eighth of an inch apart, so that, at each application, the skin is penetrated at six distinct points. I have frequently used this instrument, and it has yielded very satisfactory results. The galvanic and benzine cauteries may also be used advantageously in the treatment of telangiectasis.

In the subcutaneous venous telangiectasis, where the arterial capillaries of the skin are not involved, the skin may be dissected from a portion of the surface of the tumor, and a small globular cautery may be made to penetrate the morbid growth. In this way the disease may be cured, and the formation of a disfiguring cicatrix may be avoided.

III.—The actual cautery is employed in the removal of morbid growths which are situated in narrow and deep cavities, where their removal by excision would be attended with the danger of uncontrollable hemorrhage, as in the fauces, and in the deeper parts of the vagina and the rectum. In such cases the galvanic cautery is most advantageously employed, either by encircling the neck of the tumor with a platinum wire, which is then heated by means of a galvanic battery, or by excising with the cautery knife. Care should be taken not to apply too high a degree of heat, or to penetrate the tissues too rapidly, as the danger of hemorrhage would thereby be greatly increased.

IV.—The interior of a morbid growth greatly distending the vagina may be destroyed by repeatedly plunging into it a heated cautery iron, thus reducing its bulk, and making it possible to extract it through the vulva. In this way I succeeded in removing an enormous fibroid mass arising from the posterior lip of the os uteri, and filling the pelvis, so that I could not move it until I had reduced its bulk with the cautery. The operation was performed in the Presbyterian Hospital, in New York, and was reported to the New York Academy of Medicine. In the performance of the operation I had the advice and assistance of Prof. T. G. Thomas.

V.—The actual cautery is a remedy of great value in the treatment of severe and obstinate articular inflammation. I have had large experience in the application of the remedy to this class of cases, and I can confidently recommend it to the profession as a most valuable therapeutical agent. I have usually employed, in these cases, a globular cauterizing-iron, attached by a narrow stem to a wooden handle. I heat the iron to a white heat, and apply it so as to penetrate through the skin into the subjacent connective tissue. I usually apply it at two to four points, the patient being in a state of anesthesia at the time of the operation. I direct ice-water dressings for a few hours, and subsequently the ointment of balsam of Peru, or of salicylic acid.

As illustrations of the beneficial effects of the application of the actual cautery in articular diseases, I will select two cases out of a considerable number in which the remedy seemed to me to be the efficient means of preserving life.

The first case was that of a young man who was admitted into the Presbyterian Hospital, under my care, for retention of urine, resulting from a very close stricture in the bulbo-membranous portion of the urethra. He was a young man of intemperate habits, and a very unfavorable subject for surgical treatment. I could not succeed in introducing any instrument through the stricture, and as the bladder was greatly distended, I plunged into it above the pubes, a hollow needle connected with an aspirator, and drew off a very large quantity of urine. I repeated the aspiration morning and evening for three days, and finding the stricture impassable, I then proceeded to perform external urethrotomy without a guide. Having divided the stricture, I was able to pass a steel sound thirty millimetres in circumference through the whole length of the urethra into the bladder. There was no further trouble in the evacuation of the urine, but three or four days after the operation, the patient had an attack of acute synovitis of the right knee. He suffered severe pain and tenderness in the affected joint, and there was a great amount of constitutional disturbance. The limb was supported in a slightly flexed position, on a double inclined plane, and the usual remedies were employed to combat the inflammation. But for a number of days the case went on from bad to worse, and I had serious apprehensions for the life of the patient. I then had the patient etherized, and applied the actual cautery at four points, two on each side of the joint. The application was a very thorough one, extending deeply into the subcutaneous tissues. On recovering from the anesthesia, the patient expressed himself as being greatly relieved since the application of the cautery. Two hours after the application his temperature was 2° lower than before the cauterization, and the average temperature for a fortnight after the application was 2° lower than for a corresponding period before. A steady improvement in the condition of the patient occurred until the time of his discharge from the hospital.

The second case was one of a boy about ten years of age, whom I saw in Jersey City in consultation with Dr. Quimby. When I was summoned to the consultation I was not aware of the nature of the case. I found the boy suffering greatly from morbus coxarius in its third stage. The leg was flexed upon the thigh, and the thigh upon the trunk, so that the knee was almost in contact with the chin, and every attempt to extend the limb occasioned great agony to the patient. There was great febrile excitement, with high temperature, rapid and feeble pulse, and very marked emaciation. The patient could not be placed in any position in which he was free from pain, and his rest was greatly disturbed by his constant sufferings arising in part from the distorted position of the limb. The patient was etherized and the limb was then brought down into an extended position, parallel with its fellow, and maintained in that position by extension with a weight and pulley. There was a fire burning in the grate, and the poker was readily heated to a bright red heat, and applied behind the trochanter major, burning through the thickness of the skin to the extent of two-fifths of an inch in breadth and about three inches in length. The extension of the limb and the cauterization were followed by an immediate improvement in the con-

dition of the patient. The pain was relieved, the fever subsided, and the appetite and strength returned. When I saw him a few months afterwards, his limb was straight and free from deformity, but the hip was in a state of fibrous ankylosis. He was able to walk with a firm step; he had a ruddy complexion, had gained many pounds in weight, and presented the appearance of perfect health. It appeared to me that the treatment which was employed had been the means of saving him from the rapidly approaching fatal termination of his disease.

VI.—I have found the actual cautery, in some cases, an efficient means of restoring motion to paralyzed limbs. The cases in which I have been successful have been for the most part those of peripheric origin, where there was no morbid condition of the nervous centres. The cases have been chiefly those where a limb has been paralyzed by pressure upon its principal nerve, or by some other form of mechanical injury. The form of cautery which I have used for this purpose has been chiefly the moxa, or the burning of a combustible body upon the surface of the limb. I generally place three or four pieces of camphor along the course of the nerve, surrounding each piece with a coil of wet rag, and set fire to them, allowing them to burn until they are consumed, or extinguishing them with the wet rag if they seem to be burning too long. Each piece of camphor is of a conical or hemispherical shape, from three-eighths to half an inch in diameter. The action of the moxa applied in this way seems to be more exciting than that of the cauterizing iron, and it does not occasion as profound disintegration of the tissues.

VII.—I have employed the actual cautery with great satisfaction in the treatment of a number of cases of severe, protracted, and obstinate neuralgia. I can recall several instances of severe neuralgia of the anterior crural nerve which were promptly and permanently relieved by the application of the cautery at two or three points over the seat of the pain.

A few months ago I removed a deep-seated tumor from the neck of a woman about 50 years of age. The tumor was situated beneath the sterno-cleido-mastoid muscle, which was partially divided during the operation. The wound was dressed antiseptically, but not with all the details of Lister's method. It united substantially by the first intention. Soon after she began to complain of severe neuralgic pain on that side of the neck. Failing to relieve the pain by milder methods, I made a free application of Thorp's multiple cautery at a number of points over the seat of pain, with entire relief. After the lapse of a number of weeks the pain returned, and was again relieved by another application of the cautery.

I have applied the actual cautery for the relief of neuralgic pains in various parts of the body, and have seldom failed to obtain marked alleviation, if not absolute removal of the pain.

VIII.—I have employed the actual cautery for the relief of cystitis, with a degree of success which seems to me to warrant further trials of the remedy in obstinate cases of that very distressing disease. Several years ago I was attending an old gentleman, who was suffering severely from prostatic cystitis, and the neck of whose bladder was very intolerant of the introduction of instruments, so that it was found impracticable to carry out a thorough system of catheterization and irrigation of the bladder. I proposed to him the application of the actual cautery as a probable means of relief. He inquired whether I had ever used the remedy in a similar case. I replied, that I had not; but having derived great benefit from its

use in severe and obstinate cases of inflammation affecting other deep-seated organs, I reasoned from analogy that it would be likely to exert a favorable influence in cystitis. He refused to allow a trial of the remedy. I afterwards had an opportunity of testing the value of the cautery in the following cases:

CASE I.—Patrick Reddy, *ætat.* 63; born in Ireland; admitted to Presbyterian Hospital on the 6th June, 1877, under the care of Dr. Briddon.

Previous History.—Twenty years ago the patient first noticed that the left side of the scrotum was swollen, and he complained of pain over the region of the left kidney. The scrotal swelling was about half the size of a man's head. He wore a bandage with relief. For the last three months there has been a prominence above the pubes, attributed to a distended bladder. At this time, on walking, he would be obliged to pass his urine once or twice per hour; if he failed to do so, it would dribble away. This condition grew worse, until two weeks ago, when he could no longer pass a stream of urine by voluntary effort; but, unless the bladder were emptied with a catheter, there would be a constant dribbling. On rectal examination, the prostate was found to be moderately enlarged. A large prominence could be seen and felt above the pubes, caused by the distended bladder, supposed to contain two or three quarts of urine, as twenty ounces were drawn off without perceptible diminution of the swelling. The patient was sounded for stone, with a negative result. A large swelling was found on the left of the scrotum, about the size of a cocoanut; it was thought to be a hydrocele, but on applying the dioptric test, it was not found to be translucent.

Directions were given to introduce a catheter three times a day, and draw off a portion of the contents of the bladder, not emptying it entirely for several days, to avoid the shock which would be likely to occur if the over-distended bladder were too suddenly evacuated.

June 7th.— $\bar{\xi}$ l. drawn off; abdomen still prominent; 8th. $\bar{\xi}$ lxx. drawn off; 9th. $\bar{\xi}$ xc. drawn off; 10th. $\bar{\xi}$ lxxxij. drawn off; 11th. $\bar{\xi}$ lxxiv. drawn off. Urine is of a much darker color; on examination, it is found to contain pus and blood-corpuscles in large quantity.

13th.—The average daily quantity of urine drawn off by the catheter has been about $\bar{\xi}$ lxxv., in addition to which an estimated quantity of $\bar{\xi}$ vij. to x. has dribbled away. His temperature has risen to a point varying from 100 to 104 in the evening. At each catheterism he has complained more or less of a feeling of prostration.

25th.—Since the last date the patient has complained of severe pain when the catheter has been introduced. He has had numerous chills with febrile paroxysms. The urine is drawn off with difficulty, in consequence of the presence of several false passages communicating with the urethra. During the past few weeks there has been marked progressive emaciation. To-day the house-surgeon, Dr. Buechler, tapped the hydrocele, and drew off about $\bar{\xi}$ xij. of an albuminous fluid.

30th.—Since the last report, patient has had daily injections of gr. $\frac{1}{2}$ acetate of lead dissolved in two ounces of water. To-day it was stopped, and two ounces of a solution of a drachm of salicylic acid in a pint of water were directed to be injected three times a day to prevent the decomposition of the urine, which had become quite fetid.

July 7th.—In addition to the five grains of sulph.

quinia, which the patient is taking morning and evening, he was directed to take $\frac{3}{i}$. of infus. diosm. crenat. four times a day.

16th.—The urine is for the most part quite clear, but sometimes it becomes fetid.

19th.—Patient has recently had several attacks of diarrhœa and vomiting, for which a mixture containing sulph. morphæ, tinct. capsic., and chloroform has been ordered. The dose of infus. diosm. crenat. has been increased to $\frac{3}{ij}$. three times a day, and a twentieth of a grain of sulphate of strychnia was also ordered to be taken morning, noon, and night. He was also ordered to be faradized daily, one pole being brought into communication with the lumbar region, and the other with the perineum.

20th.—The vomiting and diarrhœa have ceased.

Aug. 1st.—The patient came under my care to-day. The urine is drawn off with a catheter, and the bladder washed out at regular intervals as before. Appetite and general condition somewhat improved.

Aug. 15th.—The urinary symptoms remain stationary. Changed the injection to nitric acid, in the proportion of one drop to an ounce of water.

30th.—Etherized the patient and applied the actual cautery at two points above the pubes, to a sufficient depth to destroy the skin.

Sept. 1st.—There is a marked improvement in the condition of the patient. The pain in the region of the bladder is greatly relieved. The urine, instead of constantly dribbling, is retained ten minutes or more at a time, and then comes in a small stream and without pain. In every respect the patient expresses himself as feeling much better than at any previous time since he entered the hospital. He bears the introduction of instruments much better than before the cauterization.

6th.—For two or three days there has been a hard swelling in the perineum, to the left of the rhaps. It is slightly painful and tender. Poultices have been applied to it. It is now reduced in size, quite hard, free from pain, and very slightly tender on pressure.

12th.—The patient does not retain his urine quite as well as immediately after the cauterization. But he continues to improve in health and spirits. His bladder is still washed out with water acidulated with nitric acid.

22d.—Ordered Ung. Sabin. to keep issues open.

29th.—Patient sits up the greater part of the day. He walks about the ward, and feels in every way stronger and better. He can sometimes retain his urine for an hour or two after the irrigation of the bladder. The lump in the perineum has increased in size, and has again become painful. Ordered poultices to be reapplied.

Oct. 1st.—Fluctuation was detected. A puncture was made, but no pus escaped.

2d.—A little pus escapes from the opening, mingled with urine.

10th.—Most of the urine escapes through the opening in the perineum. The patient is in good spirits, eats with a good appetite, and has a healthy complexion.

30th.—Patient continues to gain strength. He can retain his urine for three or four hours, and he ejects it in a good stream, and with considerable force.

Nov. 5th.—The acid injections now cause some irritation, and are directed to be discontinued, and the bladder to be irrigated with simple tepid water. The dose of the sulphate of strychnia is reduced to one-thirty-second of a grain, three times a day.

27th.—The patient was discharged from the hospital in a good state of health, cured of his incontinence of urine, and evacuating his bladder by voluntary effort, and without pain. He did not hesitate, at any time after the cauterization, to ascribe his improvement to the application of the cautery.

CASE II.—Simon Stanley, ætat. 62. Born in Ireland. Admitted into Presbyterian Hospital, May 13, 1878, under care of Dr. Briddon.

Previous History.—About forty years ago patient had gonorrhœa, which lasted about six months. He denies having had any other venereal disease. Five years ago, while lifting a heavy weight, he had a hernial protrusion, which has not occasioned any serious trouble. Otherwise he has enjoyed good health until about two years ago, when, without any assignable cause, he began to suffer from a desire to urinate every fifteen or twenty minutes. When he retained his urine a longer time, he suffered pain. He continued in this way about a year, when he became worse, urinating once in five to ten minutes, and suffering pain in the glans penis. This pain was relieved immediately after he evacuated his bladder. He urinated more frequently during the day than during the night.

Present Condition.—Patient complains of pain in the lumbar region, with frequent desire to urinate, and pain in the glans penis before evacuating the bladder.

Examination of Urine.—Sp. gr., 1010. Reaction slightly acid. Slight pulverulent sediment.

On microscopical examination, found pus corpuscles, epithelial cells of the bladder, mucus, and no casts. On chemical examination, slight traces of albumen were found. The following prescriptions were ordered:

R. Liquor potassæ,
Tinct. hyosyami, $\bar{a}\bar{a}$ $\frac{3}{ss}$.
Aque ad..... $\frac{3}{ij}$.
M.

Sig. A teaspoonful in half a tumbler of water three times a day, after meals.

R. Tritici repent..... $\frac{3}{ij}$.
Aq. bullient..... Oij.
M.

Sig. The whole quantity to be taken in twenty-four hours.

14th.—Urine can be retained longer; patient suffers less pain, and feels stronger. An attempt was made to sound him for stone, but the bladder was so irritable that the sounding was unsatisfactory.

20th.—Patient was etherized, water was injected into the bladder, and patient was sounded with Thompson's searcher, but no stone was detected. The prostate was found to be enlarged.

21st.—All medicines were discontinued. Ordered a solution of eight grains of acetate of lead in a pint of water. One ounce mixed with an ounce of hot water, to be injected into the bladder and allowed to escape. This injection to be made three times in succession, to be followed by immediate escape of the fluid, and then a fourth injection to be retained.

24th.—There is some improvement in the symptoms.

29th.—As the vesical irritation continues to be very troublesome, Dr. Briddon had the patient etherized, and applied the actual cautery above the pubes, making an eschar about an inch in diameter.

30th.—Patient feels better; he retains his urine longer, and suffers no pain on micturition.

June-12th.—Continued improvement.

17th.—Patient is suffering from toothache. Ordered three drops of Fleming's tincture of aconite to be painted on the gums every two hours. It afforded immediate relief.

July 11th.—The vesical symptoms are steadily improving. Yesterday, while patient was attempting to get out of bed, he bruised one of his testes. Today it is swollen and painful. Cloths wrung out of ice-water were ordered to be applied.

12th.—The ice-water afforded no relief, and was accordingly discontinued; warm poultices were substituted. The washing out of the bladder was temporarily discontinued.

16th.—Ordered the following prescription:

R. Ext. belladonna..... ʒ j.
Ung. simpl..... ʒ j.
M.

Sig. Anoint the scrotum over the inflamed testicle.

18th.—The orchitis has entirely subsided. The washing out of the bladder is ordered to be resumed.

Aug. 20th.—Continued improvement.

Sept. 7th.—Patient was discharged at his own request. His general health is much improved. He can retain his urine from one to two hours while he is going about, but when he is recumbent he is obliged to evacuate his bladder more frequently.

Dr. Briddon and myself were both satisfied that this patient was greatly benefited by the application of the actual cautery.

In the two cases of cystitis which I have reported, the improvement following the application of the actual cautery was so prompt, so decided, and so persistent, as to constitute a strong argument in favor of a further resort to the remedy in severe and obstinate cases. A careful consideration of the facts in connection with these two cases will show clearly that I do not propose the actual cautery as a substitute for other well-known remedies, but as an auxiliary to be used in conjunction with them. In our attacks on disease, we may well imitate the tactics of a skilful general, who, while he leads the main body of his army to attack the enemy in front, at the same time sends a chosen division to the flank or rear of the hostile position, that the rout may be more certain and more complete.

IX. The last use of the actual cautery which I will propose, is in the treatment of varicose veins.

In the great majority of cases of varicose veins of the lower extremities, the palliative treatment, by methodical pressure, is to be preferred to any attempt to obliterate the diseased veins. And the introduction of elastic bandages for this purpose, as advocated by Dr. Martin, of Boston, in an essay read before the American Medical Association, has furnished the profession with a far more reliable means of carrying out this indication than it had previously enjoyed. But, nevertheless, there are cases of extreme severity in which the disease cannot be controlled by palliative measures, and the obliteration of the diseased veins affords the only chance of placing the patient in a position to engage in the active pursuits of life. In such cases I would suggest the actual cautery as a means of accomplishing this desirable end. It is only recently that my attention has been drawn to this method, and I have only resorted to it in one instance. The patient was a man who had passed middle age, and who had suffered much inconvenience from a varicose condition of the saphena vein and its branches, on one of his legs, greatly interfering with his ability to work for his living. I

used canterizing needles at a large number of points along the course of the enlarged veins. The local inflammation following the application was very slight, and there was scarcely any constitutional disturbance. A radical cure was promptly effected. An account of this case was published in the *MEDICAL RECORD* of Jan. 18, 1879.

If similar results should follow the application of the remedy in a considerable number of cases, it will constitute a valuable addition to our therapeutical resources.

ON THE TRAUMATIC ORIGIN OF SUB-FASCIAL, DEEP-SEATED, OR COLD ABSCESS.

COMMONLY CALLED CONSTITUTIONAL OR SCROFULOUS ABSCESS.

By LEWIS A. SAYRE, M.D.

(Read before the Medical Society of the State of New York, Feb. 6, 1879.)

UNDER the head of "Scrofulous Abscess," Prof. Samuel Gross (*A System of Surgery*, Vol. I., p. 141, 1866) remarks, that "The scrofulous abscess is of such frequent occurrence, and possesses, withal, such distinctive features, as to entitle it to a separate consideration." "It is never met with except in strumous constitutions."

Psoas abscess he regards (Vol. II., p. 184) as an "essentially strumous disease, which can occur only in persons of a strumous disposition."

Dr. J. M. Chelius (*System of Surgery*, Translated by J. F. South, Philadelphia, 1847, Vol. I., p. 57) states that cold abscesses "are always the consequence of a general cacochemic or dyscrasic affection."

Geo. H. B. Macleod, M.D., F.R.C.S.E. (*Outlines of Surgical Diagnosis*, First Am. Ed., New York, 1864, p. 63), remarks, that "cold or chronic abscess occurs generally in young persons of a lymphatic or scrofulous temperament."

Dr. Frank H. Hamilton, A.M., says (*The Principles and Practice of Surgery*, New York, 1873, p. 40) that, "chronic or cold abscesses occur almost exclusively in persons of feeble constitutions, and especially in persons of strumous habit."

From the careful observation of several cases of deep-seated abscess that have come under my personal care, occurring in persons of previous good health and from healthy parents, and in which cases the disease could be distinctly traced to a traumatic origin, I am inclined to doubt the statements of the above quoted authorities and the generally prevalent opinion that these abscesses must necessarily be connected with a constitutional cachexia and arise from a constitutional condition without some local exciting cause. In fact I am inclined to doubt even the possibility of their existence without being excited by some local injury, even when occurring in persons with a depraved constitution. I am very much more inclined to agree with the statement found in *A System of Surgery*, extracted from the works of Benjamin Bell, of Edinburgh, by Nicholas B. Waters, M.D., Philadelphia, in 1792, where we find (page 432, under the head of Lumbar Abscess) the following: "This disease seems, in general, to be induced by a bruise, twist, or some other injury of the small of the back." It is my opinion that the etiology of all other deep-seated abscesses, excepting specific and glandular enlargements, will be found to be the same as Benjamin Bell has here given for lumbar abscesses.

Many of these abscesses may arise from a blow or bruise, but most of them arise from a wrench or strain of the muscles, in many instances tearing off more or less of their fibrous insertion at their periosteal attachments. In many instances these attachments are so deep-seated as to give no local manifestations that can be detected, or when superficial they are not of sufficient extent to attract immediate attention to the slight exudation, or effusion which takes place; this exudation or effusion is the result of a strain or rupture of some tissue, but owing to the fact that it is situated in a locality which is normally poorly supplied with absorbent vessels, is not taken up, and being unsuspected, the effusion is continued, and being increased by constant irritation and motion, finally undergoes a degenerative metamorphosis into pus.

The pus may be at first very small in amount, and being deep-seated, unsuspected, and not detected, increases in quantity and burrows in different directions in the tissues, taking that course where the least resistance is met with, and may thus continue burrowing for many months, or even years, until the pus has found its way, by a more or less tortuous course, to the surface of the body, where it can be detected as a fluctuating tumor. During all these months the retained pus has been a noxious element in the system, and has produced the constitutional disturbance which we find in connection with this disease, as the result of this absorption to a greater or less extent, thus poisoning the system, or, by its mere mechanical presence, producing pressure upon the adjacent parts, thereby interfering with their nutrition and vitality, and causing pain by pressure upon the nerves, thus keeping up a continuous irritation, until finally the general system becomes involved, and we thus have the constitutional disturbance produced by the presence of the abscess instead of the abscess being the result of a previously vitiated constitution, as is generally supposed.

Thus it will be seen that we have had for a long time in the system the very conditions which are sufficient to deprave the general health even of the most robust, and, owing to the fact that this depraved condition of the general health is usually observed before the pus has reached the surface, or the abscess has been detected, the profession has been wont to attribute the abscess to the depraved condition instead of what is the true explanation, namely: that the depraved condition is due to the presence of the abscess.

The following are a few of the cases that have come under my personal observation and have led me to make the above remarks.

CASE I.—B. H., Tenth Street, New York; age twelve years, brought to me in June, 1876, by Professor T. M. Markoe, M.D., with the following history:

Patient's father died at about fifty years of age, from disease of the heart. Mother is a robust, healthy woman, and she has six other children, all of whom are healthy. This boy had always been a healthy child until the summer of 1875, when he spent some time in the White Mountains, in Vermont. At the hotel where he was staying there were several cases of sickness which were attributed to bad drainage and the contamination of the water thereby. After his return to the city in the fall he seemed to have a general malaise, weakness and loss of appetite without any distinct symptoms, but he was thought to be suffering from malaria. Quinine and tonics were used without benefit. In the month of February, in getting out of a bath-tub his brother suddenly discovered that one of his buttocks was larger than the other;

this being made known, Dr. Markoe, who had the case in charge, was again sent for and his attention drawn to the swelling. He discovered an abscess under the gluteal muscles of the left side and extending above the crest of the ilium. He opened this abscess just above the posterior crest of the ilium in the lumbar space, and gave exit to a very large amount of pus, the exact number of ounces not being determined. A spica bandage was applied and worn. The abscess discharged for some months and finally closed, but every few weeks it would break out again and discharge. This was the condition when the patient was brought to me in June. The above condition was looked upon by Dr. M. as the local manifestation of a malarial and constitutional disorder.

Upon stripping the patient and making an examination I found the left gluteal region much broader and flatter than the other, with a swelling upon the posterior portion of the thigh three inches below the tuberosity of the ischium. Upon pressing this tumor pus escaped through the opening which had previously been made above the posterior crest of the ilium. A long flexible probe was then passed into this opening downward and backward over the ilium towards the sacrum, then bent forward and downward and made to be distinctly felt upon the posterior aspect of the thigh, some three or three and a half inches below the tuberosity of the ischium, but no dead bone could be detected. A counter-opening was now made at this point which gave exit to some two or three ounces of pus. The probe being passed in at this lower opening went directly upward and inward and immediately came in contact with dead bone at the tuberosity of the ischium. So soon as the location of the dead bone was determined the young lad exclaimed: "Why! that is the very place where I got hurt when the horse bucked with me in the mountains last summer." Upon a more careful inquiry it was discovered that from the day of this injury, which he received while riding, he complained for some time of severe pain at that place, having difficulty in sitting down, and was obliged to suspend his horseback exercises. From this time he acquired the habit of sitting upon his opposite buttock, which gave rise to a twist in the body which the family had been disposed to attribute to his general debility.

From the above history it would seem that the boy's trouble was clearly due to a traumatism, and this view is further strengthened by the fact that he was perfectly healthy previous to the injury which he had received. Probably the reason that this injury had been overlooked and forgotten is, that he only complained of the local tenderness for a few days. This tenderness afterwards subsiding, and being lost sight of by the prominence of his general debilitated condition, which was due to the irritation of the pus which had been formed at this point, and being so deep-seated, was not detected, nor even suspected, until months after, when the pus had made its way externally under the gluteal muscles upward and presented itself as a fluctuating tumor above the crest of the ilium.

The diagnosis now being clear that we had a case of necrosis of the tuberosity of the ischium, a free incision was made down to the dead bone and the necrosed portion removed. Carbolized water was freely injected, escaping through both openings; an india-rubber drainage tube was drawn through the upper opening to the lower opening, traversing the incision over the tuberosity. The wound was dressed with Peruvian balsam and oakum, and the walls of

the abscess firmly supported by a roller bandage. From this time the boy's improvement was rapid, and terminated in a perfect recovery, and he has since remained so, showing no sign of constitutional taint whatever; but on the contrary is an exceedingly vigorous and robust boy.

CASE II.—A very similar case will be found in the *London Lancet* for July, 1871, occurring in the service of Mr. Callender, of St. Bartholomew's Hospital. The patient was a man who had been treated in the hospitals of London for six years for serofulous disease of the hip-joint. Various abscesses upon the back and thigh had been discharging during all these years and had gradually exhausted the patient. I was called in consultation as to the propriety of excising the hip-joint; but upon examination I found that the hip joint was perfectly sound, and that the disease was necrosis of the tuberosity of the ischium. Mr. Callender made an incision down to the tuberosity of the ischium and removed a piece of necrosed bone, and the man made a rapid recovery. It was then discovered that the man had some years previous been a stage-driver, and had received an injury at this point from the jolting of the stage while riding over rough roads, and this had resulted in a necrosed condition of the ischium.

CASE III.—In September, 1878, I was called by telegraph to Wilmington, Delaware, to see a gentleman, with Dr. W. R. Bullock and Dr. Jas. A. Draper, who was supposed to have hip disease. The patient had been an active, robust lawyer, between forty and forty-five years of age, who had been taken ill some six months previous with what was then supposed to be rheumatism of his left hip. After some weeks of fruitless treatment he was sent to the hot springs of Virginia; but as he grew gradually worse and more feeble Dr. Cabel, of Virginia, advised him to return to his home in Wilmington. At this time it was suspected that caries of the hip-joint had become developed, and Dr. Agnew, of Philadelphia, was called to see him, who decided that the hip-joint was not organically involved; but the patient was now so far exhausted that he thought no treatment would be of avail, and hence suggested nothing. I was then telegraphed to to see him, and reached the patient twenty-four hours afterwards. I found him delirious, greatly prostrated, and in a profuse perspiration; in fact, presenting all the symptoms of pyæmia. Upon a careful examination I was enabled to corroborate Dr. Agnew's opinion in regard to the hip-joint not being involved. I, however, detected a large abscess deep under the gluteal muscles. By firm pressure over the gluteal region a fluctuating tumor appeared upon the posterior and outer portion of the left thigh. Dr. Bullock had already suspected an abscess in this region, and had aspirated it just before my arrival, but obtained nothing. I therefore made a free incision over the fluctuating tumor over the outer portion of the thigh and gave exit to a very large amount of pus. The ordinary probes were not of sufficient length to reach the bottom of the abscess; a silver catheter was therefore passed, and with it I detected a ridge of denuded bone about the middle of the ilium along the line where the gluteus medius muscle is attached. The catheter was then turned with its projecting point towards the surface and a counter opening made through the gluteal muscles, when this curved line could be distinctly felt uncovered of its periosteum. A drainage tube was then drawn from one opening to the other. The patient never became entirely conscious, and died at the end of a week of pyæmia. After the abscess had been discovered, and

the location of its origin definitely fixed, which was the origin of the gluteus medius muscle, some gentlemen friends of his, being present, stated the following circumstances:

In March last he had acted as one of six pallbearers in carrying a very large man, weighing nearly three hundred pounds, to the church, and back to the hearse, and then to the grave. One gentleman remembered distinctly of his complaining that he had hurt himself at that point when he attempted to lift the coffin, but it had entirely passed from their minds until this time. Another friend who was present said that the night after the funeral the patient spent the evening with him at his house, and in getting up to go home he placed his hand upon this portion of his hip and said that he had either strained it or had got rheumatism. From this time the trouble continued until he was sent to the hot springs of Virginia as above stated.

CASE IV.—W. K., Forty-ninth Street, near Fifth Avenue, New York. Forty-three years of age; a vigorous, robust, and well-developed man, who in going down his front stoop, which was glazed with ice, slipped, and in attempting to save himself from falling, made a great muscular effort, and was seized with a pain in the upper and anterior portion of his thigh about four inches below Poupert's ligament. He was brought in a carriage to my house immediately after the accident. There were no external appearances that would attract attention to any portion of his thigh unless it might be a very slight depression at the point I have mentioned. At this point the pain was so intense that I could account for it in no other way than that he had ruptured some of the fibres of the crureus, or torn them from their periosteal attachment. I advised complete rest in bed, with the leg elevated and thigh lifted, and the application of a firm roller bandage, carrying it over the thigh; this treatment to be kept up for a week or ten days until the parts had time to regain their integrity. The patient seemed to think I was making a more serious case than the appearances would justify, and sought other advice. He was told that it was a matter of trifling importance and that he might go about his work. . . . In the course of about five weeks he detected a discoloration of the thigh at some distance from the point of injury, both upon the inside and outside. About three months afterwards I was again called to see him and found a large abscess in his thigh, which I aspirated and afterwards opened antiseptically after Lister's plan, and he then made a prompt recovery.

CASE V.—A. M. S.; age two and a half years. Brought to me in January, 1853, with symptoms of lumbar abscess. The patient at this time was in a tolerably good condition. Upon examination I thought I detected deep-seated pus; a consultation was held by Drs. Willard Parker and Valentine Mott, who were unable to detect fluctuation and advised the local application of iodine and the internal administration of cod-liver oil. In the following March or April the patient returned to the city, and Drs. Parker and Valentine Mott saw him in consultation with me, and both agreed at this time that my first diagnosis was correct, and that there was deep-seated pus. The abscess had now become quite marked and easy to recognize; they advised a valvular incision upon the left side. It was my wish to have a free incision, but being overruled, the abscess was evacuated by a valvular incision, the air being cautiously excluded and the wound hermetically sealed and a bandage placed over it. The patient went to the country in

June, and in July following there were two valvular incisions made upon the right side; both times with my protest, as I was anxious for a free incision. On account of the reduced condition of the patient he was again sent to the country, near the sea-shore, in order that he might get the benefit of salt water bathing and sea-air. In September I was called to the sea-side to see him as he was thought to be dying. He had become greatly emaciated, had hectic fever, entire loss of appetite, and was drenched with a copious perspiration. The tumor was now quite prominent, particularly upon the right side. The father now gave his full consent for me to proceed with the case as I desired, as he would prefer to have him die to have him suffer as he was then doing, and wished me to perform the operation which I had at first proposed. I immediately made a careful incision around the posterior crest of the ilium, giving exit to a large amount of pus, and upon exploration I at once came in contact with necrosed bone extending from the superior to the posterior spinous processes of the crest of the ilium and leading down to the junction of the sacrum and the ilium, this portion being denuded of its articular cartilage, and was carious. A considerable portion of the necrosed bone was scraped away and the wound filled with Peruvian balsam and oakum, and the child put to bed.

After the incision had been made and the bone was found diseased, the mother then said that that was exactly the place where her child had hurt himself by falling off from a trunk backwards against the base-board, while they were at Saratoga, in the August previous to the time of my seeing him. She had forgotten all about this until it was brought to her mind by determining the location of the diseased bone.

From the hour of the operation he improved in all his symptoms; the hectic fever subsided, his sweats ceased, and his appetite returned. The wound went on discharging for some five or six months, at the end of which time it closed. The patient subsequently made a complete and perfect recovery, and grew to be a vigorous and robust man, able to perform the active duties of a civil engineer upon our Western frontier.

This patient was seen fifteen years afterward by Dr. LeRoy M. Yale, who met him and entered the following note in my history book: "The patient is in no way inconvenienced by the old disease; no sign of it remains, save a cicatrix some four inches in length, which has considerably contracted in size since the incision was made."

CASE VI.—L. H. S., Fifth Avenue, New York, age 20. He had previously enjoyed perfect health. He began one afternoon to complain, without apparent cause, of feeling sick and unable to continue his daily avocation. He complained of a circumscribed pain upon the right side between the ninth and tenth ribs, at the point of their greatest curvature. In the evening of the same day he was seized with excessive nausea, and vomited freely the food which he had taken during the day, which was almost wholly undigested. The next morning he complained of this localized pain, which led me to suspect that he had received some injury at this point. I questioned him very closely, but he positively asserted that he had in no wise been injured. The case progressed, but as he was no better, and fearing some grave visceral disturbance, I called Dr. Austin Flint in consultation, who, upon a careful examination, could detect no serious difficulty, and gave a favorable prognosis under expectant treatment. The patient for a time remained able to sit up and to go out riding, but after some weeks he began to have chills one or more times per day, and his gen-

eral prostration became much more marked. Dr. A. L. Loomis, then saw him in consultation with Dr. L. M. Yale, a number of times, both looking upon the case as one of malarial origin, and that the liver was involved. Mercury and quinine were advised and taken in liberal doses for some weeks without any improvement. Blisters were then applied over the liver, and repeated at intervals of a week for some time; tincture of iodine was also locally used. His general health became completely broken down, and upon a more careful examination Dr. Loomis now decided that there was chronic enlargement of the liver from malarial poisoning, which could probably be relieved by a two years' residence in a high altitude. The pain and difficulty of breathing at this time had become so great that the patient had become unable to take exercise even in the easiest riding carriage, and he was taken to the Hot Springs of Virginia, for the purpose of having the "Hot Spout" which is celebrated for its action upon the liver after mercurials have failed to produce the desired effect. I might here state that the idea that the liver was the source of the trouble was maintained, notwithstanding there was no jaundice whatever of the skin or conjunctiva, and the stools were natural in color. I accompanied the patient on his Southern trip. We reached Richmond by steamer, the patient bearing the trip with a considerable degree of comfort; but his trip from Millboro to the Springs, though only sixteen miles distant from the railroad station, took three days, during which time the patient suffered immensely from the jolting of the vehicle in which he was riding. On arriving at the Springs I found Drs. Cabel, of Virginia, and Stewart, of Georgia, and a number of other well-known Southern physicians, who at my invitation examined the patient and manifested a great deal of interest in the case. All these gentlemen were of the same opinion as Dr. Loomis; I could not agree with them, and still felt quite confident that there was deep-seated pus and that it was not connected with the liver. The first day that the patient was subjected to the "Hot Spout," the temperature of the water being, I think, 98° or 100°, he was much more comfortable, and this bath was followed by an exceedingly dark colored evacuation from the bowels. This gave great encouragement, and I was inclined to adopt the views of my medical friends. But in the course of two or three days his breathing became much more rapid, and the distention over the liver and lumbar region becoming more distinct, I felt confident that I detected fluctuation, and decided to explore it even if it were connected with the liver, inasmuch as five months had elapsed since the commencement of the trouble, which would have been quite time for peritoneal adhesions to have taken place. In the presence of Drs. Stewart, Cabel, and a number of other medical gentlemen whose names I cannot now remember, I made a puncture with a tenotome nearly two inches in depth; no pus escaped, but as the instrument could be easily moved from side to side, I was confident it was in a cavity, and by partially withdrawing the instrument, which was narrower in the blade than at the heel, pus escaped beside it, and I therefore, without removing the knife, made a four-inch incision diagonally across the quadratus lumborum muscle, which gave exit to an exceedingly large amount of pus, I think something over a quart. This gave the patient instant relief from all his worst symptoms. Some days after, while dressing the wound, I discovered a prominent tumor in the right hypochondrium, upon the pressing of which pus was found to escape in the opening in the lumbar region.

Some days after this the tumor increased in size and required firm pressure to evacuate its contents; a consultation was had with the medical gentlemen there present, and it was decided to make an incision down upon this tumor rather than to run the risk of the further burrowing of the pus. A careful dissection was made through the superficial and deep fascia, external oblique and the transversalis muscles, and I immediately came in contact with pus and some four or five ounces evacuated. A probe being passed in, and being found too short, a catheter was substituted and made to travel under the upper border of the tenth rib. A wire was then placed within the catheter and it was found pressing firmly against the transverse process of the tenth dorsal vertebra. A careful incision was made down to the end of this catheter, the wire withdrawn, and a rag, wet with carbolized oil, passed through the eye of the catheter and drawn through the wound, thus giving it free drainage. This procedure gave the patient great relief, and from that time his improvement was rapid and within a few weeks he was brought home. When the rag which had been introduced to give free drainage to the part had remained in about two months, it was then divided in the middle and made into two. This was in September. In the January following, as the sinuses still remained open and it was impossible to close them, Dr. A. B. Crosby put the patient under chloroform and connected the openings by a free incision under the border of the tenth rib, its whole length. After this had been done I found upon examination a half inch band of transverse fascia, behind which was pus. This I cautiously divided. It was then discovered that the last digitation of the serratus magnus muscle at the eighth or ninth rib had been torn from its attachment. When the patient recovered from the influence of the chloroform and his condition was explained to him, he immediately asked if lifting could have done this, and stated that the day before he had been taken sick he had strained himself by trying to raise the hind wheels of a carriage which were frozen in the mud, by placing his shoulders underneath the axle. From the time the fascial band above referred to was divided, and free exit was given to the pus, he began to improve, and completely recovered in about six months, and has remained in perfect health.

ALBUMINURIA IN PERSONS APPARENTLY HEALTHY; WITH THE PROPER METHOD FOR DETECTING IT.

By JOHN MUNN, M.D.,

ASSISTANT MEDICAL DIRECTOR UNITED STATES LIFE INSURANCE COMPANY, HANT, NEW YORK.

For several years past it has been the custom among many of our life insurance companies to require an examination of the urine when persons have made application for a policy, though only in cases where the amount was large, as, for example, \$10,000 or over, or where, from the personal history or physical appearance, a kidney difficulty was suspected. From the fact that nearly ten per cent. of all the deaths of policy-holders in the United States Life Insurance Company, from whose records these figures are taken, occurred from Bright's disease, it was considered judicious to require an examination of urine in as many cases as possible, with the view of ascertaining in what percentage of applicants the urine was abnormal. This work was undertaken in the latter part of 1877. The result was that so many cases of albuminuria

were discovered among those presenting themselves for insurance, that an examination of the urine was deemed necessary in the case of each applicant, and accordingly an order to this effect was issued by the executive. This furnished the opportunity to study the urine of persons apparently in perfect health and it was determined to make careful records of each case, using the most delicate means possible to detect any variation from the normal condition.

For our purposes, it was necessary to be able to discover albuminuria in its incipency, and to do this special precautions were taken. It was found that after having boiled urine and added to it nitric acid, albumen, even though present in considerable quantity, might easily be overlooked if the test-tube were not perfectly clean and bright, or if it were not held in a light properly shaded. It is not sufficient to hold the tube before a dark background, as is sometimes done, as the light from the window or burner dazzles the eye. It is necessary that the light enter the room through a comparatively small opening, and that it fall upon the test-tube, allowing the eye of the observer to rest upon a background entirely dark.

The case with which one may detect any solid substance in a liquid may be readily appreciated when we remember how completely filled with floating particles the atmosphere appears when a ray of sunlight enters a dark room through a small aperture, while in the same room with open windows the air seems perfectly clear.

After many experiments, the following plan has been found to answer the purpose fully: I have placed immediately below the window glass, and extending up to it, a large square of black pasteboard. The dark window shade is then drawn down to meet the upper margin of this pasteboard, and carried out at the bottom about one foot. Immediately under this the test-tube is held. By this method nothing but reflected light meets the eye. If anyone will place in a perfectly clean test-tube urine containing a considerable quantity of albumen, boil the upper portion, incline the tube to an angle of forty-five degrees, allow two or three drops of nitric acid to trickle down to the bottom, hold before an open window, or an unshaded burner, and afterward place in light reflected as described above, he will lose his faith in tests for albumen as ordinarily undertaken.

It is important that the acid should be carefully added, drop by drop, while the tube is in the reflected light, as in this manner the test is far more delicate. It has also appeared that albumen in a urine, alkaline, neutral, or even faintly acid, will not be readily detected. The urine must be distinctly acid, and when it is not, should be rendered so by the addition of acetic acid, and thoroughly well shaken before boiling. Unless this precaution is taken, albumen will be overlooked in many cases.

It is also necessary that the urine be allowed to stand quietly in the test-tube at least five minutes after the nitric acid is added, at the expiration of which time, if no cloudiness appears, it may safely be pronounced non-albuminous.

The following table is made up of cases coming under my own observation. The heart and lungs were normal in each, and nothing satisfactory was found to account for the albuminuria. Nor was there anything in the physical appearance of any, save possibly two, to warrant any suspicion of a renal disease. Each one considered himself in perfect health and really appeared as if he were. They were all excluded solely on account of albuminuria, and formed eleven per cent. of those presenting themselves to me for examination.

In nearly every case two or more specimens taken at different times were examined and albumen found in each.

No. OF CASE.	OCCUPATION.	AGE	WEIGHT	HEIGHT	PULSE.	ALBUMEN.
1	Bank clerk....	21	123	5-8	76	Well marked.
2	Com. merch't.	23	180	5-6	86	Slight trace.
3	Lawyer.....	23	138	5-7	78	Abundant.

23	Mer. agency business.....	61	161	5-9	78	Well mkd trace.
24	Publisher.....	61	165	5-8½	66	A trace.

In a number of cases, the applicant having been advised of the cause of rejection, returned to me, saying that his family physician had examined a specimen of his urine, and found it perfectly normal. I have been able, however, in a few such instances—indeed, whenever a personal interview has been had—to convince the physician that the examination, as made by him, would not have detected any but a considerable quantity of albumen, and great surprise was expressed on demonstrating the case with which it is possible to overlook albumen, unless proper care is taken in the analysis. Such experiences have strengthened the conviction that tests as ordinarily made are far from being satisfactory, and I feel compelled to make this assertion boldly.

While it is impossible to deduce definite conclusions from the limited number of cases given above, it is interesting to note that albuminuria was found as frequently in the young as in the old, half the number being under forty-five years of age; that in nearly half the number there was excessive weight; that the pulse was rapid in nearly all, though very little importance may be attached to this. Casts were found in but two cases.

There is great difference of opinion as to what the clinical significance of albuminuria really is, but that it should exist in eleven per cent. of a large number of individuals considering themselves perfectly healthy, and with no discoverable cause for its presence, is a fact worthy of consideration. When no discomfort is produced by it, our attention as physicians may not be called to these cases until a late period, when other manifestations of kidney disease appear. Consequently such cases are rarely observed. It is proposed to keep the cases here noted, together with such others as may come to my notice, under close observation; to examine the urine from time to time, and note whatever changes occur in it and in the general condition of the individual.

* Applied for insurance and was accepted in December, 1877; no examination of urine. Applied again in three months, but was rejected, both sugar and albumen being found in urine. Died three months later.

By so doing for a number of years, we may hope to approach a little nearer to the real significance of albuminuria.

These investigations thus far seem to warrant the following conclusions:

1. Albuminuria does exist in a far greater proportion of individuals apparently in perfect health than is ordinarily supposed.
2. The method of testing as commonly practiced, fails to detect any but a considerable quantity of albumen, and it is absolutely necessary to use light properly shaded.
3. The urine, if not distinctly acid, must be rendered so before boiling.
4. In an alkaline urine, unless properly acidulated before boiling, at least five minutes must elapse after adding the nitric acid before it is safe to pronounce it non-albuminous.
5. The early morning specimen frequently contains no albumen, while that voided later in the day does. Consequently a morning specimen, which physicians usually require for analysis, is not to be depended on in testing for albumen.
6. Carelessness in procuring specimens, which are often received in an unclean vessel, or placed in a partially cleansed bottle, or in foul test-tubes (unfortunately used by many physicians), renders the analysis untrustworthy.

The vessel receiving and conveying the specimen, and the test-tubes used in testing it, must be absolutely clean; the re-agents used must be chemically pure.

The production of bacteria is favored by uncleanness in the urine receptacle. If such urine remains for a few hours in a warm room in a stoppered or unstoppered bottle, a cloud will appear, indicating the presence of bacteria in myriads. At this time no test for albumen is satisfactory. By careful filtration through many successive layers of ordinary filter paper we can remove many of them, but nothing short of porous clay is thoroughly successful. This latter method is obviously inapplicable. The moral is, never examine any but fresh urine for albumen.

50 E. THIRTY-FIRST STREET, N. Y.

Reports of Hospitals.

THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Prepared for THE MEDICAL RECORD.)

SOME INTERESTING POINTS IN THE DIAGNOSIS AND PROGNOSIS OF TYPHOID FEVER.

THE case was that of a sailor, admitted to the hospital on the 27th of January, who had been in good health until four days before his admission, when he complained of chilliness, of fever, and of nausea, but of no headache. His nose bled profusely, and his bowels became very loose. Upon his admission *his face was singularly flushed*, and he had a severe pain in his back. His temperature was 104½° F., his pulse 92, and his respirations 24 to the minute. Nothing could be detected in the condition of the lungs to account for the heavy flush on his face. Upon examining the urine it was found to contain granular hyaline casts and bladder-epithelium. It was re-examined, with the same result.

The man remained in the same condition, with morning remissions and evening exacerbations, and with a few bronchial râles in his lungs, until the afternoon of the day after his admission, when profuse epistaxis supervened, and the characteristic rose-colored spots appeared on his abdomen, which grew swollen and tympanitic. *Still there was no headache.* On the evening of January 31st the man's temperature was 103° F. Between January 27th and February 1st there was *never a difference of more than one degree between morning and evening temperatures.* On the morning of February 1st the pulse was only 84, and the respirations 20 to the minute. The tongue was of the characteristic appearance—dry, cracked, reddish at spots, devoid of coating, varnished-looking. The typical spots on the chest and abdomen were slightly raised, and disappeared upon pressure. There was some gurgling in the right iliac fossa, and a moderate amount of abdominal distention. The bowels, after admission, were easily controlled by a single opium suppository daily.

On February 1st the face was still flushed. The breathing was rather harsh, and there were a few dry râles in the lungs. Still no headache, and intellect clear.

Dr. DaCosta, in his examination of the case on February 1st, and remarks upon it, developed some points of much novelty and interest.

The first sound of the heart he found to be very feeble, and there was most marked throbbing of the vessels at the root of the neck. He considered the case to be different from the great majority of cases.

He wished to lay great stress upon the presence of albumen in the urine upon the eighth day of the disease. The case would have to be very closely watched. The presence of the albumen might be explained in either one of two ways—(1) there might have been pre-existing disease of the kidneys as a complication of the fever, or (2) the typhoid fever had produced the disease of the kidneys. If the latter alternative were the true one—and it so seemed to him—the case was a very grave one, for the albumen was noticed as early as the fifth day of the disease. *Early albuminuria, as a symptom, never occurs in the course of typhoid fever unless the case is to be a very grave one.* Albumen is quite commonly found in the urine of typhoid fever patients in the third week of the disease. *The slight difference between morning and evening temperatures so early in the attack was another bad sign.*

Furthermore, the first sound of the heart was thus early altered. Alteration in the first sound of the heart does not usually occur until late in the course of the disease. *When the heart is affected early, it becomes a warning.*

In closing, Dr. DaCosta wished to call attention to the existence of flushed face, *without any disease of the lungs.* *It always was enough to raise suspicions as to the nature of the disease, especially when accompanied by great throbbing of the vessels at the root of the neck.* This fact had struck him many years ago, and, upon entering a sick-room and finding these coincident symptoms, he used to make a rough diagnosis of typhoid fever at once, without any further examination.

All these symptoms being as they were, it was determined to shape the treatment accordingly. Up to February 1st, the man had been taking ℥ij. of whiskey daily. This quantity was at once increased to ℥ij. Together with this, gtt. x. of muriatic acid was given every four hours. The daily distributed dose of quinia was gr. x. The man's diet was very

carefully regulated, consisting principally of beef-tea and milk. Diarrhœa was checked by opium suppositories. The patient was sponged morning and evening with tepid water.

Feb. 20th.—The man is now convalescent, having been carried through the attack by careful treatment. The albuminuria has disappeared.

ARTERIO-VEINUS ANEURISM.

There was recently a very interesting case of this description in the wards: that of a man whose pistol had been discharged accidentally while he was taking it out of his pantaloons pocket, the load passing completely through the right thigh from within outward, and piercing both the femoral artery and vein. Immediately after the accident the man was cognizant of a sawing sound caused by the passage of the arterial blood into the vein. When the patient returns from his home whither he has gone to settle his affairs, it is the intention of the attending surgeons to ligate the femoral artery above and below the point of injury.

INDICATIONS AGAINST PARACENTESIS THORACIS.

The case had been in the wards for some time with the history of an attack of pleurisy following exposure. When the patient was first admitted in November, examination revealed an old right-sided pleurisy with some evidence of abscess of the right lung. Subsequently the signs of pleuritic effusion developed rapidly, and it was very evident that there was considerable effusion in the lower part of the chest.

The question which arose was whether, with the evidence of a right-sided pleurisy, which remained rather stationary, together with the suspicion of tuberculous disease, resort should be had to aspiration, or whether the endeavor should be made to get rid of the effusion by medicinal means. When the patient was first admitted he had already had the effusion for several months.

Upon thinking the case over and considering the strong probability of disease of the lung itself, though masked; finding also, no marked irritative fever, and having, therefore, no reason to suppose that the chest was full of pus, Dr. DaCosta concluded to try and get rid of the effused serum by medicinal means, and determined not to tap the chest. The result justified the conclusion reached.

On February 1st the dulness still remained low down in the right chest. The voice was transmitted from all other parts of the lung. So too, with regard to the vocal fremitus. The breathing was also fuller and deeper.

The treatment consisted principally in the administration of the tincture of the chloride of iron with acetate of ammonium. Occasionally a Dover's powder was given at bedtime. The food was generous and counter-irritation was frequently made with iodine or blisters.

From the good results already shown, Dr. DaCosta was confident that this treatment ought to be persevered in.

The patient is at present taking a tablespoonful of Basham's mixture four times daily, and a tablespoonful of cod-liver oil thrice daily, on account of the suspected latent disease of the lungs.

The case was regarded as proving that it is never wrong in old cases of pleural effusion to give a fair trial to medicinal means first, and never to try tapping until we are quite sure that all other modes of relief are of no avail.

The three points particularly suggested and empha-

sized by the case were: (1) that we should be guided rather by the effects of an effusion than by the time it has lasted; (2) the value of Basham's mixture and repeated counter-irritation in the treatment of chronic pleurisy; (3) the possibility of tuberculous disease of the lung as a co-existent factor is always an additional reason for not tapping, since surgical interference should never be attempted when this complication exists.

THE TREATMENT OF FRACTURED PATELLA.

Dr. Thomas G. Morton has treated all the cases of fracture of the patella which have been brought into the wards for several years past with his improved modification of Malgaigne's hooks. In every instance the treatment has been permanently successful. Dr. Morton's first modification of the Malgaigne hooks consisted in making the hooks longer and straighter, but this improvement was shown to be of but slight advantage. Dr. R. J. Levis then made a further modification of the Malgaigne pattern, by cutting it into two separate pairs of hooks. This modification also was thrown aside after using it once. The last and most useful modification by Dr. Morton consists in cutting the hooks into two separate pairs, each pair consisting of one fixed and one movable hook. This modification will be fully explained and its benefits illustrated in an article from the pen of Dr. Morton, soon to appear in the *American Journal of the Medical Sciences*.

THE TREATMENT OF FRACTURED CLAVICLE.

Dr. D. Hayes Agnew treats fractured clavicle by perfect rest on the back in bed, with the head slightly elevated. But as the patient soon becomes restless, and as it is impossible to secure perfect quiet after the third day unless a nurse be secured to arrest every motion of the patient both by day and night, at the end of that time and when the ends of bone have, as it were, lost their disposition to get out of place, the patient is raised carefully from the prone into a sitting posture and put in restraint by the introduction of an axillary pad four inches wide and five inches long, and tapering rapidly to a point, which elevates the arm and supports the shoulder, while a long strip of adhesive plaster, $3\frac{1}{2}$ inches wide (Sayre's dressing), is passed round the body with a loop to support and elevate the arm.

ANEURISM.

Dr. James Hutchinson has seen considerable benefit derived from the administration of very large doses of the iodide of potassium. In one case lately in the wards, as much as sixty grains of this drug was taken thrice daily with the effect of quite markedly diminishing the size of the aneurism. Some time since in the case of an aneurismal sac bulging from the sub-clavian artery, Dr. Richard J. Levis carried pieces of horse hair through the walls of the sac and so succeeding in producing partial coagulation of the blood, but not enough to materially benefit the case.

PNEUMONIA.

The routine treatment of pneumonia in the wards of the hospital consists in the internal administration of from eight to twelve grains of quinia daily, together with a moderate amount of nitrate of potassium and of the tincture of digitalis every two or three hours. Plenty of stimulus is administered. In a case recently under treatment, Dr. DaCosta gave in place of the nitrate of potassium a teaspoonful of the spirits of ammonia in water every three hours as an alkali.

This use of ammonia (as an alkali) was so successful in Dr. DaCosta's hands that Dr. Hutchinson tried it in one of his cases with equally good results.

SURGICAL SHOCK

Is treated by the hypodermic injection of carbonate of ammonium mixed with brandy.

Progress of Medical Science.

INTRAVENOUS INJECTION OF MILK.—In a case of extreme exhaustion consequent on typhoid fever, Dr. McDonnell, of Dublin, made an intravenous injection of milk with very gratifying results. The operation was performed on the 22d of January, in the presence of several members of the profession. The milk was fresh drawn from a cow on the premises, and about ten ounces passed into a vein at the bend of the elbow. During the injection the pulse rose and became fuller and stronger; immediately after the completion of the operation the pulse became feeble, the respiration labored, and the capillaries congested. This stage of depression lasted about two hours, when a distinct and truly remarkable reaction took place. The patient passed a quiet night, and expressed himself as much better and stronger on the following day. On the seventh day after the operation the patient was making good progress, taking nutriment freely, although, of course, weak and exhausted.—*The Lancet*, February 1, 1879.

THE PHYSIOLOGICAL RELATIONS OF HYPOXANTHIN AND LACTIC ACID.—Hypoxanthin, or, as it is sometimes called, sarkin, is well known to be a frequent, if not constant constituent of the blood of leukæmic patients, and the means of detecting it were greatly improved by Salkowski. It remained uncertain, however, whether it was to be considered as always present in healthy blood. This, and several other points in regard to it, have recently been investigated by George Solomon, who has published the results at which he arrived in the *Zeitschrift für Chemie* (B. II., 1878, p. 94). He finds that hypoxanthin is a normal constituent of the marrow of the bones in man, and that it is also normally present in various glandular organs. It is always present in blood obtained after death, both in man and in dogs. Its presence in the blood and other organs after death in leukæmic patients affords no assistance in determining the pathological changes occurring in that disease. With rare exceptions, hypoxanthin is only found in the blood after death. Its absence from blood drawn from a vein during life is probably due to the fact that it rapidly undergoes oxidation. The same holds good of xanthin. Lactic acid is also nearly constantly present in the blood after death, and its presence in the blood of leukæmic patients after death is therefore destitute of significance. Lactic acid is absent, and probably for the same reason that hypoxanthin is absent, in the greater number of specimens of blood drawn from the veins during life. The lactic acid of the blood abstracted after death is, in all probability, the result of the decomposition of the carbo-hydrates of the blood. Lastly, hypoxanthin and xanthin are produced outside of the body by the action of the pancreas ferment on fibrin.—*The Lancet*.

PHYSIOLOGICAL ACTION OF NARCISSA.—About two years ago Mr. Gerrard, of London, extracted from the flowering bulbs of the common daffodil an alkaloid,

to which he gave the name Narcissa, and which seemed, in its physiological action, in many respects, to resemble atropia. Later, from the bulbs which had done flowering, an alkaloid was obtained, apparently similar in its general chemical characters to the first, but differing markedly in its physiological action. These two alkaloids were carefully studied by Sidney Ringer, M.D., and E. A. Morshead, M.R.C.S., and their investigations show that the alkaloid from the flowering plant: I. Dries the mouth. II. Checks the cutaneous circulation. III. Dilates the pupil, especially in topical application to the eye, the dilatation being preceded for a short time by contraction. IV. Quickens the pulse. V. In a great measure antagonizes the effects of muscarin and pilocarpin on the heart of frogs. VI. Directly applied to the frog's heart slows and weakens its contractions.

While the alkaloid extracted from the bulb after flowering: I. Causes copious salivation. II. Probably increases cutaneous secretion. III. Internally applied slightly contracts the pupils; topically applied, dilates the pupil, but less so than the alkaloid of the flowering plant. IV. Slightly relaxes the bowels. V. Causes slight faintness and nausea.

An extract of the flowered bulbs exhibits emetic and purgative properties not possessed by the alkaloids. Mr. Gerrard also prepared alkaloids from the bulbs of the common snow-drop (*Galanthus nivalis*), both before and after flowering, and these exhibit a complete parallelism with the alkaloids from the daffodil.—*The Journal of Physiology*, Jan., 1879.

DIABETES; DEATH FROM SO-CALLED ACETONÆMIA.—Kussmaul was the first to direct attention to that peculiar mode of death in diabetes to which he gave the name acetoneæmia. The symptoms he observed were sudden oppression in the chest, as if there were some obstacle to breathing; violent, and for the most part hurried, respiratory acts; accelerated heart's action, and rapid coma, which lasts till death. Dr. Southey reports three cases, occurring in his own practice, in which death took place preceded by similar symptoms, and which he considered identical with the acetoneæmia of Kussmaul. They were all three marked by a peculiar soporous condition, with dry tongue and cyanosis; not hurried breathing but pulmonary blood-stasis; no evidence of lung consolidation; noisy, stertorous, apoplectic-like breathing, but no paralysis; intellectual capacity retained, but exercised only under strenuous and unwilling effort. Of the precise nature of the blood-changes, which gave rise to these clinical phenomena, Dr. Southey is uncertain; but in all three cases, when the respiratory symptoms appeared, the peculiar sweet-hay halitus of diabetes was absent, and, if this halitus be due to the excretion of acetone by the lungs, the suppression of its excretion may account for the accumulation of the poison in the blood; or the sudden increase of its quantity in the blood may arrest the respiratory circulation and chemical interchanges.—*The Lancet*, Feb. 8, 1879.

ŒSOPHAGOTOMY.—Œsophagotomy, though an established operation, is sufficiently rare to render the following case of interest. On July 6th the patient swallowed a piece of the vulcanite plate belonging to her artificial teeth. The fragment was a flat triangular bit, half an inch long by a quarter broad, and had a piece of silver wire a quarter of an inch long projecting from one end. A pricking pain was soon complained of, in the course of the œsophagus, a little above the midpoint of the sternum, increased by the recumbent position, and in that posture accompanied

by a feeling of suffocation. Nothing but fluids could be swallowed, and even these occasioned considerable pain. A week after the accident profuse salivation set in, which lasted for two days. On July 21st her voice began to fail, and by August 1st she could only speak in a whisper. The pain grew worse, and on the 16th of August the operation of œsophagotomy was performed in the usual manner. After some search the missing fragment was found, lying against the anterior wall of the œsophagus, about two and a half inches below the œsophageal notch, and was easily removed with a pair of urethral forceps. The upper portion of the wound was then brought together, but the lower part was allowed to gape, and was covered by a piece of lint dipped in carbolic oil. For the first forty-eight hours she was fed *per rectum*, afterwards *per vias naturales*, a portion of the food trickling through the wound, but no other inconvenience being experienced. After this the patient did well, the wound was healed by October 10th, and by November 21st the voice had become quite natural. At this date there was no pain, and no difficulty in swallowing.—*The Lancet*, Feb. 1, 1879.

EPITHELIOMA IN KASHMIR.—According to Dr. Maxwell, epithelioma is much more common in Kashmir than in other parts of India or in Europe; but considerable clinical variation from the European disease is observed. Fully 50 per cent. of the cases recorded occurred on the abdomen, and 27.7 per cent. on the thighs, regions but seldom affected in Europe, where the face is affected in about one-half of all cases. Dr. Maxwell's epitheliomas usually presented the appearances of irregular, nearly circular or oval ulcers, from the size of a sixpence to that of a crown, with everted indurated edges, an irregular coarsely-granular base, of a yellowish or brick-red color, discharging a little purulent or sanguino-purulent fluid, which, on microscopic examination, was sometimes found to contain characteristic nests or globes of epithelial cells. They are of slow growth, and are much less malignant than the European epitheliomas; no case of return of the disease being recorded during ten years of observation. The lymphatic glands are rarely affected, are never cancerous, and but seldom enlarged. Age and sex appear to have about the same influence as in Europe. The disease is attributed to the kángri or fire-pot, which every Kashmiri carries about with him or her, for purposes of warmth. These kángris consist of clay pots, about four inches in diameter, encased in wickerwork, and contain live charcoal, or wood ashes. They are carried under the night-gown-shaped garment, which both men and women wear, and are often in contact with the abdomen. A portion of the wickerwork not uncommonly wears off the heated clay vessel, which, if carelessly held, may severely burn the skin of the abdomen and thighs. Many of the sores had, to the patient's knowledge, originated in burns from the kángri. It is interesting to remark the analogy between the heated clay-pipe causing epithelioma of the lip in Europe and the heated-clay kángri, causing the same disease on the abdomen of the Kashmiris.—*The Lancet*, Feb. 1, 1879.

UNUNITED FRACTURE.—An hypodermic injection of glacial acetic acid (℞.v.-x.) between the ununited ends of the bone is highly recommended by Mr. Fitzgerald, surgeon of the Melbourne Hospital, in the treatment of *ununited fractures*. At first it is attended by very sharp pain; this rapidly subsides. In this surgeon's hands this treatment has been uniformly successful.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 29, 1879.

THE STATE BOARD OF HEALTH OF ILLINOIS AND THE MICHIGAN MEDICAL ACT.

IN our last we alluded to the Illinois State Board of Health, a body created by the Legislature of that State with full power to regulate the practice of medicine within its jurisdiction. Among the edicts of this board was one forbidding what it termed unprofessional advertising. It was not long before the board had an opportunity of testing the powers conferred on it by statute. The board, it appeared, took exception to certain advertisements inserted in the Chicago papers by a Dr. Aiken, and notified him that if continued it would revoke his license. Upon this he applied to the Cook Circuit Court for an injunction to restrain the Board of Health from interfering with his license. The decision of the court was to the effect that the Legislature had given the State Board full power to regulate the practice of medicine as it saw fit, and that if it declared that certain advertisements or other practices were unprofessional, and ordered their discontinuance, that there was no doubt but that the statute gave them plenary jurisdiction in the matter. The injunction was therefore refused. The case was then carried to the Appellate Court of Illinois on the question of the constitutionality of the law creating the State Board of Health. The Appellate Court has recently decided that the law is constitutional, and confirms the board in all its powers. It will be remembered that this board is a sort of mixed commission, consisting of representatives of the regular, homœopathic, and eclectic methods of practice. The good work which it has already done in Illinois can hardly be over-estimated, and unless some unforeseen obstacle should arise, that State will soon be purged of the most obnoxious forms of quackery. The influence of the Illinois law has, however, not been confined to that State, but has been felt in neigh-

boring States, and even here, in the arrival and settlement of many who have failed to come up to the requirements of the Illinois regulations. Let a few more Western States pass similar laws, permitting only those who have had a medical education to practise, and we will soon see New York State deluged with a class of practitioners who will find the climate of the East more congenial than the one they are obliged to leave.

The act passed by the Legislature of this State May 11, 1874, should have been denominated an "Act for the Encouragement and Protection of Quackery," for in its practical applications it has well merited this title, as a careful perusal of it in connection with some of the other laws of the State will show. Some of the laws still extant, however, appear to give the various county medical societies of the State certain powers in this matter which should not be overlooked, but be brought to an early test. The State has, however, conferred co-ordinate powers on certain sectarian societies, and it becomes a question of serious moment whether the regular societies should alone undertake the defence of the rights of the profession, or whether there should be a co-operation of all educated and legally qualified practitioners; or, again, whether it is not better to leave everything *in statu quo*. Without a fuller acquaintance with all the facts in the case we are hardly in a position to come to a definite conclusion. It is certain, however, that unless a change occurs it will soon be a difficult matter for the average qualified practitioner to earn a respectable livelihood. Those now in high position and of established reputation may not experience suffering in their own day, but to our certain knowledge a goodly number of thoroughly qualified and capable men are at present sadly straitened in their circumstances, and their number is likely to increase rather than diminish, unless something be done to prevent the increase of unqualified practitioners. As we before remarked, this matter should receive the prompt attention of the officers of the county societies. We have every reason to believe that the officers of our own county are fully aware of the gravity of the situation, and have taken the questions involved into very serious consideration; but what action they will take in the matter we have no means of knowing.

A medical bill has been recently introduced into the Michigan Legislature which appears to receive the general approbation of the profession of that State. Instead of a mixed board, like that of Illinois, it provides three separate State boards of co-ordinate jurisdiction, representing the regulars, homœopaths, and eclectics. In fact, it is little better than the New York law of 1874, and, if the bill becomes a law, Michigan will soon share with New York the distinction of being the paradise of quacks.

THE LUNG-PLAGUE.

UNDER the authority of a recent act of the State Legislature active measures have been taken for stamping out pleuro-pneumonia amongst cattle. All veterinary surgeons or owners of cattle are now required to report every case of the disease that comes under their care, and the animal is then either quarantined, or slaughtered. The emergency demands such energetic action, for contagious pleuro-pneumonia is an insidious, obstinate, and destructive disease which only the most persistent efforts can eradicate. These our Legislature, with a somewhat surprising foresight, has provided for.

The contagious diseases of cattle have in many respects a peculiar history, and their study may in time throw much light upon human pathology. Thus there is a unique disease in the form of the Texas, or splenic fever, of which the pathognomonic lesion is an enlarged and disintegrated spleen. This affection is enzootic, and is analogous somewhat to remittent fever in man. Yet it can be propagated, like cholera, by the excrement, and has therefore peculiar features, whose further examination may add to our knowledge of infections.

The present lung-plague has a morbid anatomy and a clinical history which resemble, in many respects, acute phthisis. It is, however, an infectious and purely contagious disease, and has its pathological analogue in small-pox.

Contagious pleuro-pneumonia began its recorded ravages in Europe nearly two hundred years ago. It was imported into this country in 1843, and has since then spread all along the Atlantic States, from Massachusetts to Virginia. It was driven out of Massachusetts and Connecticut after a seven years' fight, but has remained in the other States to a greater or less extent. The disease has an incubation of from one to sixteen weeks, or even more. At the end of this incubation it may develop only in a latent form, giving but few symptoms.

These two facts of a long incubation and possible latency add to the danger and difficulties connected with the disease.

In a well-marked case the invasion begins with shivering; the temperature is 104° or 105°, and there is a cough. Without attempting to enumerate them all, there will develop subsequently the symptoms and signs, such as pain, loss of appetite, peculiar posture, mucous discharges, etc., which would naturally attend a high fever, and a pleuro-pneumonia of one or both lungs. The animals gradually become weaker, and may die within a week or two in the acute stage, or linger on to die later, with evidences of marasmus and purulent infection, or they may recover. The disease lasts in its acute stage from one to three weeks. Then follows either death, immediate or slow, or convalescence, which extends over from one to three months. The mortality varies largely, but on

an average perhaps from a quarter to a half of the cases will die. The post-mortem examination shows a pleurisy with serous and plastic exudation, and a pneumonia with fibrinous exudation which passes through the stages of red and gray hepatization as in man. Later in the disease there may be empyema, cavities, interstitial increase, gangrene, and the various forms of lung disorganization. Either one or both lungs may be affected.

A search for the germ or even constant bacteria in this disease has been made in vain. Nevertheless there is a specific virus which is contained in the breath, the blood, and secretions. The disease may be communicated through the air, by inoculation, and by the act of coition.

The men who attend the cattle may also convey it. It can be inoculated into other animals, but probably not into man. The contagium is not so active in the early part of the disease, but even during convalescence it may infect the healthy.

No treatment will modify the course of the symptoms very much, and indeed, no treatment but the axe to the os frontalis is now recommended, except in special cases.

If a drop of the fluid squeezed from the lung is inoculated near the root of the tail, it will, as a rule, cause a local inflammation only, which will nevertheless give the animal immunity for about two years. This practice is not often advisable, however, for it may produce the full disease, and it always makes the animal a centre of contagion.

Slaughtering is the only efficient method of dealing with the trouble, and this is being done largely at present. If our State continues to act with its present vigor, we may expect to be rid of this unfortunate affection in a few years.

THE SANITARY INSPECTION OF OUR PUBLIC SCHOOLS.

THE progress which has been made recently by the Board of Education in investigating the sanitary condition of school-buildings is quite significant. From the time the *New York Herald* published a report of an inspection of the public schools, last December, until the present, the pressure of public opinion has compelled an action on the part of the Board of Education which it positively refused to do before. Every person who was not a member of the board in question had good reason for believing that the sanitary condition of the schools was exceedingly bad. All suggestions bearing upon reform in such matters were ignored by the Commissioners. Medical experts spoke in vain, medical societies passed resolutions which were tabled, and even the Health Board was hampered in its spasmodic efforts at inspections. Laws which might have been made for improving the sanitary condition of the schools have been defeated because the board concluded that there was

no necessity for them. This has been the case for the past six years and until the *Herald* report was made public. At the meeting of the board, succeeding the said publication, the matter of sanitary reform was brought up, and, by a vote of nineteen to two, promptly was referred to the Committee on Warming and Ventilation, of which Mr. Wickham was chairman. This gentleman, who at first thought it was only necessary to lower the sashes in the school-rooms to secure all the necessary ventilation, had reason to change his views very decidedly as he gave time and attention to the matter. After six weeks of investigation one hundred and thirty reports were made from principals of schools regarding deficiencies in ventilation, heating, and the like. As a result of this mass of adverse testimony regarding the sanitary condition of the schools, Mr. Wickham resigned his chairmanship of the committee at the last meeting of the board, maintaining that it would take eight hours of inspection daily for some time to come to investigate the different cases properly.

The admission on the part of the distinguished commissioner, that any inspection was necessary at all, is such an important one for the cause that he may be forgiven for resigning the chairmanship of his committee at such a critical moment. From this point, however, we can count upon the chances of real progress being made in these necessary investigations, some sensible conclusions reached and some practical suggestions made. This hope is warranted by the appointment of Mr. Isaac Bell as chairman of the committee. This gentleman has so thoroughly identified himself with the cause of sanitary reforms heretofore, and has rendered such valuable service to the cause of school hygiene in particular, that his appointment on the committee will be received with the greatest satisfaction by the profession and the public at large. We have no doubt that the inspections will be thorough, and that the recommendations which will be made will bring about desirable results. Although the inspections which should have been made during the past six years will be crowded into a period that would scarcely occupy as many weeks, it is nevertheless quite important that a report should be made with the least possible delay, not only for the sake of the school-buildings which are at present crowded with scholars, but also for those buildings now in process of construction.

INSANE ASYLUM REFORM.

THE recent speech, made in the State Senate, against the Commissioner of Lunacy and his office, together with the subsequent petition to the Legislature for an investigation into the management of the State insane asylums, give ground for hope that the attempts at reform, which we have heretofore frequently urged, will at length be made. It is time that some initiative

measures were taken; and therefore, although we cannot endorse either speech or petition as perfectly just, they are both very opportune.

The Commissioner of Lunacy was attacked by Senator McCarthy, who introduced a bill to abolish the office altogether, and transfer its duties to the State Board of Charities. His charges appear to be pretty well sustained, but we wait to hear from the commissioner himself before passing judgment upon them. They apply, at any rate, rather to the fitness of the commissioner for the position than to his honesty and conscientiousness. But, whatever may be decided about the incumbent, we do not believe that his office should be abolished, or that the State Board of Charities should perform its duties. These are laborious, responsible, and important; and they should not be imposed upon an unsalaried board which is already overworked. We believe, rather, that much of the inefficiency of the present commissioner's labor is due to his being alone, with limited power and limited scope of action. It is difficult for a single individual to be a thorough inspector and reformer of the institutions of a large State. He can scarcely escape the effects of a social and political environment, both of which tend to make him lax in his duties. With a board of lunacy, however, composed of several members, and with well-defined authority and duty to keep the exact state of asylum management before the public, some genuine reform can be accomplished; and not only accomplished, but made permanent. It is by such means that British asylums have been brought to their present high pitch of excellence, and it is time for the system to be adopted by us. Indeed, it is doubtful whether an investigation into the management of the asylums, however complete, will result in any permanent good, unless some such organization is created.

Of the petition which prays the Legislature for an investigation, we will only say this: Its object is excellent, for it will disclose to the public and impress upon their attention, the undoubted evils of asylum management, already known to a few. The petition itself, however, might have been made stronger, both by dropping certain very trivial charges which only increase its bulk, and by adding such other ones as would show, what is really the case, that the State is quite as much at fault in the present matter of mismanagement, as the medical superintendents, who have to accommodate their institutions to inadequate laws, meagre appropriations, and political influences.

A NEW ANTIPERIODIC.—A decoction of *chestnut bark* (outside bark of the tree, 403; boiling water, 1 qt.; steep fifteen minutes) is extolled by Dr. R. F. Hood. Clear out the bowels with a good purge. Then let the patient take a teacupful of the decoction every three hours till the day of the expected return of the paroxysm; then wait till the 6th, 7th, 13th, 14th, 20th, 21st, and 27th days after, when repeat the same treatment for each respective day.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 26, 1879.

DR. E. L. KEVES, PRESIDENT, IN THE CHAIR.

DEFORMITY PRODUCED BY A BURN.

DR. A. C. POST presented two photographs, representing the deformity produced on the face of a young lady by cicatricial tissue following a burn. When twenty years of age she fell face foremost upon a fire. In consequence of the burn there was extreme eversion of the upper eyelid upon the left side, and considerable eversion upon the right side. Her eyebrows were entirely destroyed, and her forehead was covered with cicatricial tissue. A series of operations were performed, commencing December 22, 1876, the last being about two years after the first. The feature of special interest in the case, besides overcoming the ectropion and other deformities, was replacing the eyebrows by flaps transplanted from the temples, the hairs being plucked and trimmed to give them proper form. At the time he performed the operation he supposed it was the first time that new eyebrows had been formed; but he had subsequently ascertained that Dr. Pancoast, of Philadelphia, had done the same thing, but that the operation had never been published except transiently, and had not been known to the general profession.

The details of Dr. Post's case will appear in the transactions of the American Medical Association for 1878.

MYXO-SARCOMA INVOLVING THE LEFT SIDE OF THE UPPER JAW.

DR. POST also presented two photographs, one exhibiting a front and the other a side view, of a myxosarcomatous tumor in the left side of the upper jaw. The tumor was remarkable for its extremely rapid growth. The man, a short time before Christmas, 1878, had two or three carious teeth extracted from the left side of the upper jaw, and, at about that time, noticed for the first time that there was a tumor connected with the alveolar process. Its entire growth, therefore, had apparently taken place within about eight weeks. He was admitted to the Presbyterian Hospital, under the care of Dr. George F. Shrady, who would have operated had he not been prevented by sickness. There was obvious reason for immediate operation, the growth of the tumor being exceedingly rapid, and repeated hemorrhages having occurred, and accordingly Dr. Post performed the operation that afternoon. The specimen was presented, and consisted of a tumor which involved the entire alveolar portion of the jaw, the substance of the jaw being almost entirely destroyed. The only portion of the bone which retained its integrity was the roof of the antrum and the nasal process. There was also an enlarged gland under the angle of the lower jaw. It was the opinion of some of the surgeons that the enlargement might be merely sympathetic, and therefore the gland was not removed. There was one circumstance in connection with the operation which was a matter of some interest. At the suggestion of Dr. Briddon the nasal cavity was not opened until all the dissection above was made, and the blood-vessels secured. When that was done the head was held over the table so that the blood

gravitated away from and not towards the fauces. The first incision was made just below the orbital brim, and extending to a point over the malar bone. A second incision was made by the side of the nose, but was not completed until the orbital brim was exposed, and a section made below it into the antrum with Hay's saw. The second incision was then completed by extending it around the ala of the nose, and through the middle of the lip. The bone was then fully exposed, two teeth were extracted, the alveolar process was divided, and with the handle of a pair of forceps the mass was pried out. The soft consistence of the tumor did not permit of its removal by seizing with forceps. A portion of the growth extended apparently into the cells of the ethmoid bone. As much as possible was scraped away, and chloride of zinc of the strength of one drachm to the ounce was applied as thoroughly as could be to the portion remaining. The portions of the wound not touched with the chloride of zinc were covered with carbolic acid, one to thirty. Lint was introduced to fill the cheek, and held in position by a thread, which was passed out of the angle of the mouth around the ear and over the temple to the forehead, where it was secured by adhesive plaster. The edges of the wound were then carefully united by sutures, and the patient was left in a comparatively comfortable condition.

DR. HOWE asked Dr. Post if he experienced any more difficulty in making the necessary dissection than when the incision was at once made through the lip?

DR. POST replied that the operation was not prolonged by the method, and certainly the time during which blood flowed into the nasal cavity was diminished, and also the time which the head was held over the table was diminished.

ANEURISM OF THE ARCH OF THE AORTA UNSUSPECTED DURING LIFE.

DR. J. L. PEABODY presented a specimen of aneurism of the arch of the aorta that had not been suspected during life. The history of the case was as follows: Frank Smith, æt. 38 years, a native of the United States, single, and a seaman, about three months ago caught cold. Since that time he had had cough so severe at times as to cause vomiting and shortness of breath. One month ago he began to have purulent expectoration. He had carache upon the left side for about four weeks, but there was no discharge. A few days ago he had a chill, which was followed by fever and sweating. When admitted to the New York Hospital there was slight exaggerated respiration, but otherwise the chest signs were negative. Treatment: quinine. He had a second chill. The treatment was continued, and the chills ceased. On the 21st day dry râles were heard at the apices of the lungs, and there was a small quantity of blood in the sputum. On the 22d day a systolic murmur was heard at the base of the heart. On the 25th day the patient was suddenly seized with profuse hæmoptysis, and died before anything could be done.

Autopsy.—Body anæmic, but tolerably well nourished; no marks of external violence; no œdema; nostrils and mouth blood-stained; frothy blood on face. A few loose adhesions were found over both lungs. Trachea and bronchi filled with blood. A small sac was found on the descending portion of the arch of the aorta, just below the level of the bifurcation of the trachea. It communicated with the left bronchus by a linear opening about one-quarter of an

inch long. The size of the sac was about half that of a hen's egg. It was united by firm adhesions to the root of the left lung. Blood was extravasated throughout the lung-tissue. Heart normal in size and appearance. The other organs were normal. There was no clot in the aneurism.

PYÆMIA WITHOUT EXTERNAL WOUND RECOGNIZED OR RECOGNIZABLE UPON CAREFUL EXAMINATION—MICROCOCOCI IN THE MALPIGHIAN TUFTS OF THE KIDNEY.

DR. PEABODY also presented a microscopic specimen which exhibited micrococci in the Malpighian body of the kidney. It was prepared from the kidney of a patient who gave the following history:
